This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

PHILADELPHIA:
HENRY C. LEA'S SON & CO.
1881.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

Entered according to the Act of Congress, in the year 1881, by HENRY C. LEA'S SON & CO., in the Office of the Librarian of Congress. All rights reserved.

BY SUBSCRIPTION.

MEDICINE—Revised Edition—Just Ready.

M OF MEDICINE.

RUSSELL REYNOLDS, M.D.,

nd Practice of Medicine in University College, London.

WITH NOTES AND ADDITIONS

HENRY HARTSHORNE, M.D.,

ssor of Hygiene in the University of Pennsylvania.

ome royal octavo volumes, containing 3052 closely printed double-column pages, with 351 illustrations.

PRICES.

	Cloth.	Sheep.	Half Russia.
er volume	$5 00	$6.00	$6.50
Per set	15.00	18.00	19.50

OME I. contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.

OLUME II. contains DISEASES OF THE RESPIRATORY and CIRCULATORY SYSTEMS.

VOLUME III. contains DISEASES OF THE DIGESTIVE and BLOOD GLANDULAR SYSTEMS, OF THE URINARY ORGANS, OF THE FEMALE REPRODUCTIVE SYSTEM and OF THE CUTANEOUS SYSTEM.

Reynolds's System, as a work of reference in medicine, is unexcelled and unequalled, and should be in the library of every physician. Dr. Hartshorne, the American editor, has contributed articles on cholera morbus, cholera infantum, trichina spiralis, bronchocele, pernicious anæmia, and spermatorrhœa, besides making such additions to many other articles as the progress of medical science since the volumes first appeared, required. The task he undertook has been well performed, and the thanks of all American physicians are due to the American editor for affording them the opportunity of obtaining at a reasonable price such a magnificent cyclopædia of the practice of medicine, embodying as it does the views of the most learned members of the medical profession of Great Britain. We earnestly advise all our readers to buy the volumes and *read them.*—*Canadian Journ. of Med. Sci.*, Oct. 1880

It gives us pleasure to recommend most cordially this System of Medicine, not merely to the student but also to the busy practitioner of medicine.—*Amer. Journ. of Med. Sciences*, Aug. 1880.

Reynolds's System of Medicine is a work so full in detail, yet so exclusively practical in character, that it is indispensable as a work of reference for every practising physician. It is more nearly a cyclopædia of practical medicine than any other work with which we are familiar. In the reprint before us the entire text of the English edition has been preserved except in the case of some very elaborate tables, fully elucidated in the text, while much has been added chiefly in the form of entirely new articles on subjects not treated in the English edition. For the production of this great cyclopædic treatise, the profession owes Dr. Hartshorne, the American editor, an everlasting debt of gratitude.—*Louisville Med. Herald*, Aug. 1880.

As a work of reference, Reynolds' System of Medicine is the most thorough and complete in the English language. Each subject has assigned it a distinct author, whose special merits are fully and clearly put before the reader. We know of no work whose value so appeals to the wants of the profession and so important to the practitioner.—*Southern Medical Record*, Nov. 20, 1880.

Regarding the work as a whole, we give it our earnest commendation. It places within the reach of the average physician a series of monographs, written by some of the most eminent men of the age, upon an extremely wide range of subjects. It is the latest and best cyclopædic work on practical medicine written in our language.—*St. Louis Clinical Record*, Aug. 1880.

Valuable as the work was when issued in England, the labors of Dr. Hartshorne have added very greatly to its worth, and it can now but be regarded as the best encyclopædia of medicine extant.—*American Practitioner*, Aug. 1880.

These three ponderous volumes contain a vast amount of valuable information; as works of reference in the library of the discriminating practitioner, the medical investigator, and the medical teacher, they are of real value.—*Chicago Med. Journ., and Examiner*, Aug. 1880.

In style, economy of space, clearness and brevity; in comprehensiveness, excellence of description, and practical utility, it is admirable.—*Chicago Med. Rev.*, July 20, 1880.

As a treatise on the Practice of Medicine, the three volumes constituting this series are incomparable. Compendious in detail, and scientific in description, it can but eventually take the first place among present standard works on this subject.—*Atlanta Med. and Surg. Journ.*, Oct. 1880.

These three volumes are a whole library in and of themselves. As works of reference they are destined to be for many years regarded as the very highest authority on medical subjects. Language is scarcely adequate to express the actual value to general practitioners of such a system of medicine as this of Professor Reynolds.—*Cincinnati Lancet and Clinic*, Aug. 21, 1880.

GALVANISM, OR FARADISM? WHICH IS TO BE USED, AND WHEN?

A CLINICAL LECTURE DELIVERED AT JEFFERSON COLLEGE HOSPITAL,

BY ROBERTS BARTHOLOW, M.D., LL.D.,

PROFESSOR OF THERAPEUTICS AND MATERIA MEDICA IN JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

GENTLEMEN: We have had before us many cases in which the applications of electricity have been directed. Sometimes it is the galvanic, sometimes the faradic current which we employ for diagnosis or for treatment. A little inquiry will easily demonstrate, that, if we use electricity as it should be used, both kinds of batteries are necessary. In the purchase of an instrument, the buyer is sometimes misled by the statement that a particular battery furnishes all the currents—a primary or galvanic current, and the various secondary currents. A faradic instrument, of course, furnishes an induced current, and the induction exerted between the coils of the primary wire may be utilized, as well as that from the secondary wire, so that various modifications of the induced currents are available. But no one should be deluded into believing that a faradic battery can also furnish a galvanic current. Pray, do not understand me as saying that the two forms of batteries cannot be combined in the same apparatus. These may, of course, be put in one box, both faradic and galvanic combinations, and the dealers now make very beautiful and perfect instruments of this kind.

I am thus minute in stating these elementary facts, because I am frequently interrogated by students and physicians in regard to these points. I start out with the declaration, then, that if you expect to use electricity in a truly scientific way, you must be provided with both kinds of apparatus, either separately, or combined in one box. Much may be done by faradic application alone; but in its own sphere, and if employed merely to affect the imagination of the patient, it will be quite as successful as both. I hope none here present, however, will descend to electricity quackery, whether openly or under the guise of its scientific use. As I proceed with

the subject, I will indicate in passing the form of current used in particular cases. I wish also to address myself more especially to current delusions about the use of electricity. Let us take for illustration a common form of paralysis—hemiplegia. No spectacle is more often seen than the tinkering of an old hemiplegia with a faradic battery. The muscles are daily shaken up, and physician and patient are finally at their wits' end, for no improvement follows: No one, at all acquainted with the subject, would expect to benefit an ordinary hemiplegia by faradizing the muscles of the paralyzed members, unless two conditions existed: 1, wasting, degeneration, and impaired electro-contractility; 2, late rigidity. In many cases of hemiplegia, the muscles are of their normal size and firmness, and readily respond to faradic stimulation; then no good can be done by applying electricity. When late rigidityexists, the faradic and galvanic currents are useful if rightly applied. Observe the conditions present. On one side the flexors rigidly contracted, and drawing in the fingers on the palm. The nails cannot be cut, and the cast-off epidermis accumulating decomposes; ulcerations occur, and a horrible fetor is given forth. On the other side, the extensors of the fingers, relatively less powerful in the normal state, also, are now relatively weaker, and are unable to oppose the over-action of the extensors. As the galvanic current, when continuously applied, allays spasm and over-action, the flexors should have proper galvanic applications. As the extensors are weak and need stimulating, the faradic current should be applied to them. The same method of management is applicable to *torticollis*, or wry neck. On one side are the rigid, over-acting muscles; on the other, a group of weak or paretic muscles, quite unequal to maintain the contest with their antagonists. To galvanize and relax the one, and faradize and strengthen the other, are the obvious indications, and the successful method of treatment.

In paralyses due to disease of the spinal cord both forms of currents are applicable to diagnosis and to treatment. Thus, we meet with cases in which the muscles react differently to the faradic and galvanic currents—cases in which the muscles will not respond to faradic, but will respond to galvanic stimulation. There are other examples of paralysis in which the muscular contractility to both currents is retained; and still other cases present themselves in which the response to current stimulation is impaired merely and not lost.

I have already stated a fact, of which you have repeatedly seen the verification in this amphitheatre, that in ordinary hemiplegias the electro-contractility is preserved. When paraplegia, for example, is produced by disease of the dorso-lumbar enlargement of the cord, which is the centre for the nerves proceeding to the lower extremities, the power of the muscles to respond to the faradic current is presently entirely lost, but these paralyzed muscles are then found to contract to a slowly interrupted galvanic current. Further, when a paraplegia is due to disease of the cord, *above* the dorso-lumbar enlargement, leaving that untouched, the muscles of the lower extremities respond readily to the faradic and galvanic currents. In still other cases, say, disseminated myelitis, with lesions all along the cord, leaving tracts of healthy tissue, the muscles connected by nerve filaments to the diseased part of the cord lose their power to contract, and those muscles connected with the healthy parts of the cord retain their power to contract, on faradic stimulation. In fact, the diagnostic point is, that paralyzed members receiving their innervation from a diseased part of the spinal cord lose their electro-contractility to the faradic current, and

preserve it when that part of the cord from which the nerves are given off is in a healthy state, although elsewhere the cord may be diseased. The importance, then, of using both currents is very obvious. But there are other examples, not less striking. In cases of disease and injury of motor nerve trunks, the contractility of the muscles receiving filaments from them is variously affected. When the initial hyperæmia occurs in neuritis, the irritability of the nerve, for a brief period is heightened, and the muscular contraction occurs with abnormal readiness on faradic and galvanic stimulation; but soon the electro-contractility declines, and is then extinguished as to the faradic current, but is retained as to the galvanic current. Not only do the muscles fail to respond to the faradic current, but they respond with more than usual readiness to the galvanic current—to a less strength of current than indeed suffices to move the healthy muscles. There are differences as to anodal and cathodal opening and closing of the circuit, which are expressed in definite formula, but not to distract your attention from the fundamental proposition, I merely mention this fact. The muscles degenerate as the injuries to the nerve proceed, and finally they cease to respond to the galvanic current. If the nerve recovers from the effects of the inflammation, the contractility of the muscles to the faradic current is finally restored, and the response to galvanic excitation lessens in readiness until it becomes normal.

It has been observed that in these cases of neuritis, the response to the will, as recovery takes place, precedes by many days the response to the faradic current, reversing the order in which the loss of contractility occurred. These changes in the muscular reaction to galvanism and faradism, are entitled by Erb "the reactions of degeneration," an expressive phrase coming into general use, and with which you should be familiar. These reactions of degeneration take place when the spinal cord or the nerve trunks are diseased. They are typically exhibited in the cases of facial paralysis. A current of cold air directed against the seventh nerve in front of the external auditory foramen—the *pes anserinus*—produces, sometimes, a paralysis of all the muscles to which the nerve filaments are distributed. You have had various examples of this malady brought before you, and its peculiarities pointed out. In a short time after the muscles are paralyzed, it is found that no movements can be induced by a faradic current, never so strong, and that a galvanic current barely strong enough to cause contractions on the healthy side will act energetically on the paralyzed muscles. These facts have been exhibited in cases in your presence. If we compare such a facial paralysis with that which accompanies hemiplegia, we observe great differences in the reactions: in the latter both faradic and galvanic currents act energetically; in the former, only the galvanic produces responses.

Galvanism and faradism are much more important in the treatment of paralyses characterized by the reactions of degeneration than in hemiplegias. Both currents are required. As the galvanic current only can cause movements of the muscles, in certain cases, this must be applied until the contractility to faradism is restored—for it is found that persistent use of the former has this result. When the faradic current causes movements, it can then be continued until the cure is effected. If the degenerating muscles do not respond to either currents, then it may be concluded that the muscular elements have disappeared, being replaced by connective tissue and fat. Certain paralyses from disease of the anterior cornua of the spinal cord—infantile paralysis, for example—are character-

ized by the rapidity with which the muscles waste. These affections are designated by Charcot amyotrophic, to express this peculiarity. Electricity is our special resource to arrest these trophic degenerations. In these affections the reactions of degenerations are perfectly characteristic, and hence the galvanic current must be used until the contractility to the faradic current is restored. If the wasting of the muscles proceeds unchecked and the anatomical elements are destroyed, no electrical applications will be of any service. They must be undertaken, therefore, before the muscles are too far gone to be restored. When, by systematic excitation, the muscles have recovered their normal volume and contractility, electricity can accomplish nothing more, for the centric disease on which all depends may not be remediable.

In morbid states involving *sensibility* the faradic current is of little service. A very high tension current, with excessively rapid interruptions applied along the trajectory of a nerve, is sometimes serviceable in a neuralgia. The power to relieve pain is the property of the galvanic current. A descending stabile current is, theoretically, the best form of application to relieve the irritability of a sensory nerve, but in practice it is found that the direction of the current is of little moment, the relief being the same in what direction soever the electricity may be flowing. It follows then, of course, that the galvanic and not the faradic current is to be used in the treatment of neuralgia. The use of the faradic current in such cases is one of the medical delusions against which we must protest.

In the treatment of internal maladies the galvanic current is chiefly used. It has been abundantly proved that this form of electricity penetrates to the deepest organs and tissues, whilst faradism does not so penetrate. Galvanism affects the calibre of the vessels, and thus has an influence on the nutrition of the tissues. If the faradic current is applied directly to the sympathetic nerves, the vessels innervated by these nerves are thrown into a condition of tetanic spasm, and the blood stream is arrested. Applied on the surface, however, such effects do not follow, because the current does not penetrate sufficiently. The galvanic current does penetrate to the vessels when applied to the surface, and hence the important results which may follow its proper administration. It is important to understand the mode in which galvanism affects the circulation. We owe, I think, chiefly to the labours of Onimus and Legros the facts which I am now about to submit. The normal movement of a healthy arteriole is that known as vermicular. An impulse beginning at one point is transmitted by a succession of waves to a distant point, and as one part contracts, another dilates. Now Onimus and Legros have shown that whilst the faradic current tetanizes and stops the distribution of blood, the galvanic promotes and enlarges the vermicular movements, and thus increases the quantity of blood passing in a given time. The nutrition of organs and tissues must, necessarily, be promoted by the galvanic current. In this, probably, we have an explanation of Remak's "catalytic effects." The practical application of these principles is of much importance. If we wish to arrest hemorrhage from an organ, such as the uterus, to which we can apply the electrodes directly, which form of electricity ought we to use? the faradic or galvanic? The former unquestionably, for it not only causes strong uterine contractions, tetanizes, but it also affects the vessels in the same way. I need hardly stop to say that faradism is an excellent expedient in uterine inertia with hemorrhage.

On the other hand, suppose our object be to improve the condition

of an enlarged, flabby, and congested uterus, the vessels being dilated, the blood-streams sluggish—then the galvanic current should be applied, for under its use the tone of the vessels would be restored, and the blood-streams would be propelled with more force and rapidity. In any attempts to improve the nutrition of the deeper parts of the body beyond the reach of direct applications, the galvanic current only can be used, since the faradic does not diffuse to the necessary depth. In the treatment of those neuroses of the skin, due to changes in the condition of the sympathetic ganglia, remarkable results are often obtained from the form of galvanization known as centric. The tonic and reconstituent effects which follow the application of galvanism to the cervical sympathetic, to the pneumogastric, and to the spinal cord, are doubtless due to the increased action of the vessels and to the stimulation of the nervous apparatus presiding over the movements of the chylopoietic viscera. Also, doubtless, something is due to the action of the current on the trophic system. What explanation, soever, may be adopted, the fact remains that stimulation by galvanism of the important apparatus of animal and organic life, mentioned just now, has remarkably good effects in some disorders of nutrition. I may mention, in illustration, the curative influence of galvanism in exophthalmic goitre. I mean, of course, this malady as it does exist, free from any structural lesions of the heart and of the thyroid gland. Under the persistent use of galvanism the rapid action of the heart, the dilatation and increased pulsation of the vessels of the neck and of the thyroid, the enlargement of the thyroid due to enlargement of its vessels, and the protrusion of the eyes cease, and permanently cease in favourable cases.

There is a form of faradic application, which is alleged to promote nutrition—the general electrization of Beard and Rockwell—in which the whole surface is in turn stimulated by faradic applications to the skin. This acts on the cutaneous nerves and vessels, and does generally promote the activity of the nutritive functions, but it is slow and not efficient. Weir Mitchell applies the faradic current in another way. He throws all the muscles of the body in turn into action by a faradic current of sufficient strength. This acts by increasing the circulation and the oxidation processes in the muscles, for muscular contraction can no more take place than any force can be evolved without the consumption of material. As the most of the heat production of the body occurs in the muscular tissue, the increase of muscular contraction means increased temperature and consequent greater activity in the nutritive functions generally. Indeed, making all the muscles contract by a faradic current is exercising them, and thus Mitchell succeeds in exercising his patients without voluntary efforts on their part.

In further exemplification of the power of galvanism to affect the function of nutrition may be mentioned the solution of cataract, which, it is alleged, has been accomplished by application of a galvanic current to the affected eye. An additional case, lately published in Virchow's *Archiv*, by Dr. Neftel, of New York, has been warmly disputed by Knapp, Agnew, and Loring, who have shown that Dr. Neftel was over-sanguine.

Galvanism can alone be used to affect the condition of the brain and spinal cord. Faradism does not pass the barrier of the bony envelope to these parts, but galvanism has been experimentally shown to do so. That galvanism, and not faradism, should be used when it is proposed to reach these parts, seems, therefore, conclusive. There can be little question that galvanism is highly serviceable in certain vascular states of the intra-

cranial organs. We must bear in mind how galvanism affects the vessels, in order to apply it correctly. I have already stated that Onimus and Legros have shown how galvanism promotes the normal vermicular motions of the vessels, and is, therefore, indicated when the circulation is languid from paresis of the vessel walls. That state of the intracranial circulation which exists when atheromatous changes have occurred in the vessels, and the walls of the arterioles are yielding, and miliary aneurisms forming, and characterized objectively by failing memory, weakened power of attention, vertiginous sensations, etc., is much improved by the daily application of a weak galvanic current to the head, kept up for some weeks or months; the individual applications, however, being less than five minutes in duration.

The propriety and utility of applying galvanism to the brain, in cases of embolism and cerebral hemorrhage, are much disputed. The rule is to apply galvanism, only, after all acute symptoms have subsided. As, however, the collateral hyperæmia and œdema do much mischief, it is surely desirable to prevent or limit them. We possess no agents which can act on the contractility of the vessels with the promptness and efficiency of galvanism. If rightly applied, the current being weak, substantial good may be done in the direction I have indicated. Sudden, strong applications, shocks, may do serious harm. The relaxed state of the vessels following acute meningitis, or cerebro-spinal meningitis may be toned up, and soft, unorganized exudations remaining after the acute inflammation, absorbed, under the stimulation of galvanism, but only currents of moderate strength are at all proper. I need hardly add that faradic applications are useless under these circumstances, and could only do injury if persisted in.

As a general rule, in the neuroses of the respiratory organs galvanism is used rather than faradism, but there are some exceptions. Remarkably good results are obtained in some cases of asthma by galvanization of the pneumogastric, sympathetic, and phrenic. A very successful case has lately been reported in which faradism was alone used. I have seen hiccough promptly arrested by a strong faradic current, when galvanism was used in vain; but this success of the faradic application was due to the action of inhibition. The reflex hiccough was arrested by the simultaneous arrival at the centre of another impression. The method of treating hiccough by faradism consists in sending through the walls of the thorax a strong current, just as the spasm is about to occur. The result is—the hiccough is inhibited. Neuralgia of the cardiac plexus, of the solar plexus, and of the stomach, or gastralgia, are most effectively treated by galvanism. Torpor of the muscular layer of the large intestine may be successfully overcome by both currents, but they differ in action; faradism affects the bowel rather at the point of contact, and induces strong tetanic contractions; galvanism originates movements, which are propagated in a vermicular manner much more widely. The best results are obtained by a combination of the two agents.

No systematic attempts have been made to promote the functional activity of the chylopoietic viscera by galvanic treatment, but it is highly probable that this remedy might be used with good results. The state of functional depression, diseases characterized by impaired nutrition, etc., are those which might be much improved by systematic galvanic treatment.

Both currents are used in the maladies of the sexual system, male and

female. I have already indicated the principles regulating the employment of faradism and galvanism in uterine diseases. Probably faradism is more effective as a stimulant in amenorrhœa, as it is in uterine inertia, whilst galvanism is more serviceable in the vascular states characterized by relaxation. In the treatment of impotence in the male both forms of currents are useful, but their action is not the same. When the erections are wanting in force, due to imperfect filling of the veins of the erectile tissue, galvanism is more effective because of its power to increase the vermicular movements of the vessel's walls. When anæsthesia of the external organs exists, generally or in part, the faradic brush is serviceable.

In the treatment of affections of the chylopoietic system, one electrode properly insulated should rest in the rectum, and the other should be applied over the abdomen, all parts being brought successively within the circuit. A properly insulated electrode, flexible, and of the right length, could be readily introduced into the stomach. From such a position of the electrode, the current could be diverted to the various organs, and especially to the semi-lunar ganglion and solar plexus. The recent observations of Da Costa and Longstreth on the changes in the renal ganglion in Bright's disease, furnish an additional motive for further extension of galvanic applications by intra-stomachal electrodes.

Finally, gentlemen, as the manner of applying electrodes is important, I must say something of the details concerned. In faradic applications well-moistened sponge electrodes are used when it is desired to reach the muscles, for the conductivity of the tissues is determined by the amount of water present in them. When single muscles are to be stimulated, the olive-pointed electrodes of Duchenne are best, and they must be covered by soft leather, and not by sponge. When muscular groups of large size are to be acted on, large sponge electrodes may be used. The larger the electrode, and the more thoroughly moistened, the less the pain. When the skin alone is to be faradized, all moisture should be carefully wiped off, and some drying powder dusted over the surface. When galvanic applications are to be made, the form and size of the electrodes will depend on the object in view; for single muscles, and separate nerve trunks, small electrodes are employed; for large muscular groups, and for pain in many nerve filaments, large, well-moistened sponge electrodes are best.

The injunction, in systematic works, to add a little salt to the water with which the sponge electrodes are moistened, is proper only in the case of galvanic applications to the face and head. In neuralgias of the extremities, especially of long standing, I am convinced that we should use powerful currents, and, therefore, make the applications with large electrodes, moistened, but not with salt water. Not sufficient attention is paid to the duration and number of the *séances*. In galvanic applications about the head the sittings should not exceed five minutes, but they may be repeated several—say three—times a day. In neuralgias the applications should be more prolonged, and should be repeated at short intervals. Much better results would be obtained in these affections, sciatica, for example, if the applications of galvanism were fifteen minutes long, and repeated every three or four hours. These statements are based on some experience with these frequent applications, and are not merely speculative theories. In the treatment of muscular paralysis by faradism, it should be remembered that the muscles are readily fatigued, and that no benefit results from treatment which has this effect. As a rule, the smallest strength of current which will induce muscular contractions, is only

necessary. The individual muscles will bear exercise in this way from five to fifteen minutes, and the applications may be repeated about twice daily.

Every physician employing electricity as a remedy should give the necessary time and attention to the applications, and should resist the inclination to get through with them as quickly as possible, when numerous and fatiguing. Provided with suitable apparatus, and an adequate knowledge of the subject, the physician will find himself possessed of a most valuable remedy, capable of results which none other can achieve in its own province.

ON THE INTERDIAGNOSIS OF INSENSIBILITY FROM VARIOUS CAUSES.

By REGINALD SOUTHEY, M.D. Oxon., F.R.C.P.,
Physician and Lecturer at St. Bartholomew's Hospital.

GENTLEMEN: Questions somewhat of the following kind are likely to be put to you one day, and are full alike of clinical interest and medico-legal importance: What is the matter with an individual who has been picked up on the road insensible, irrational, or inarticulate, and about whom no antecedents whatever are known? Is he ill, drunk, drugged, suffering from brain concussion, or from coma after an apoplectic or epileptic fit?

Syncope, trance, catalepsy, and coma are names severally used by medical writers to designate states of insensibility which the lay public group vaguely under fits.

Syncope is fainting; it may be otherwise described as a condition of body in which there is a death-like pallor, with loss of muscular power and of consciousness. Trance is a state of death-like faintness in which, however, some consciousness is retained, although the person is unable to move or speak. A faint is ordinarily (when an individual has not lost a very large amount of blood) an exceedingly transitory affair. A person collapses rather than falls to the ground in a faint; his knees bend under him, he subsides into the sitting posture, his head drops forward, and by the time the head has thus sunk to the level of the heart, or below it, the circulation through the brain becomes sufficiently restored for consciousness to return. In a faint a person seldom bruises his face. Upon waking up he may feel sick or giddy, or alarmed, but his brain resumes its thinking function usually at once and entirely.

In states of trance—of which I possess no personal experience, but may refer you to accounts to be read in Smith's "Forensic Medicine," pp. 540–542, and Forsyth's "Medical Jurisprudence," pp. 125–130, 155, and pp. 165–188—it appears that the body is to all appearance inanimate, and there is no power to move a muscle, the limbs meanwhile remaining perfectly flexible. The peculiarity attached to this condition is that the individual may hear, see, and remember all that goes on about him. There is no perceptible pulse or respiration, and hence trance has been mistaken for death, but we possess no recent or philosophical observations upon this form of faint. The recorded cases do not tell us of the temperature, or whether or not the muscles react to galvanic stimulus. Burial alive in this condition, except at sea, is highly improbable, but in no case would you be justified in making a post-mortem or consigning a body to burial unless you were satisfied from the presence of rigor mortis or appearances of putrefac-

tion that death was actual. Catalepsy, again, is a rare inanimate condition; still I once had a case under my care which accorded well with the descriptions that have been given of it.

A young man of nineteen was picked up in Fleet Street insensible, not fallen, but standing stiffly, unable to move or to articulate. Here are the features that distinguish this state, all which he presented in other similar seizures which he had for several days afterwards while in the hospital. Thus while carrying something about, or sitting up in bed, or attempting to poke the fire, his eyes would suddenly acquire a fixed gaze, and he would remain arrested as it were in his act. We could set his limbs in any posture we pleased, and there he remained like a mesmerized cock, to the amusement of the nurses and other patients. I watched him on several occasions. There was not the slightest twitching or spasm of any of his muscles. His pulse was slow, and so were his respirations, his extremities cold and flabby, the axillary temperature remained natural. He would bear pinching or pricking without flinching, and took no account of our bawling his name close by his ear. There was no reason to think that he was feigning, and it would be difficult, I fancy, to feign and act a disease so well as he did. To quote from Dr. Copland's Dictionary, vol. i. p. 292: "The statue-like appearance and muteness of the cataleptic alone suffices to distinguish this disease. There is neither the lividity of asphyxia, the pallor and general flexibility of syncope, the stertor of coma, the paralysis of apoplexy, nor the movement and dreamy mental automatism of somnambulism."

Coma, however, because arising from very various causes, is the single one of the several states mentioned by them as likely to offer much difficulty in diagnosis. Coma may be due—1. To *pressure* exercised on the brain, arising (*a*) from within the ventricles, effusion therein; (*b*) from depressed fracture; (*c*) from effusions outside the brain between hair and membranes. 2. To *alteration* in molecular state of brain from some concussion, contusion, bruising, œdema, apoplectic extravasation. 3. To brain poisoning by insufficiently oxidized blood, uræmic blood, narcotics, anæsthetics, inebriants.

I cannot give you certain symptoms for diagnosing each of these causes of coma, but I may aid you in excluding some of them, and thus help you to arrive at a correct diagnosis in particular instances. The profound coma produced by serous effusion into the ventricles of the brain, to judge from what I have seen in dropsy, renal or cardiac, and by what happens in tubercular meningitis, is gradually reached through a stage of sopor. The individual at first is sleepy, then dreamy and slow of apprehension, difficult to awake, and finally incapable of being aroused at all. Reflex movements may be excited for a while, later the face is pale, the temperature falls. The breath is either Cheyne-Stokes or principally diaphragmatic and stertorous. At first there is power to swallow, afterwards acts of deglutition fail to be coördinated. The pupils are non-characteristic, but more often dilated than contracted. (*a*) The coma due to depressed fractures, or to effusion of blood or pus or fluid between the brain and the membranes, is as sudden in its advent as its cause may have been. Usually the breath is stertorous, the pupils are contracted, and the temperature is normal or above normal, the skin perspires profusely. No or only slight reflex response is made to galvanic or cutaneous stimulation.

You will be guided to the diagnosis of fractured skull by bleeding or oozing of bloody serum from the ear or nose or by ecchymosis of the eye, and towards large apoplectic effusion of blood upon the surface of the brain by the stertor of the breathing and complete absence of reflex irritability. (*b*) When the coma is due to alteration in the molecular state of the brain, local contusion, or apoplectic extravasations, the face is usually pale, the temperature fallen below normal;

the reflex irritability, although variable, is apt to be greater on one side of the body than on the other; the pupils may be unequal, and evidence of some hemiplegia is generally discoverable in the muscles of the face or eye.

It seems like hair-splitting in diagnosis to dwell upon what may aid you to distinguish between coma due to general compression of the brain substance and coma due to more localized brain injury, with general circulatory and nutritional disturbance, but I give you the best clues I can, such as have served me sometimes well; the evidence of any hemiplegia in a case of profound coma is always in favour of localized injury of brain rather than of general pressure.

The coma may, however, be due to some brain-poisoning, the sources of which I have grouped under heading 3. Now, deficiency of oxygen and excess of carbonic acid in blood produces coma—as, for example, in the inhalation of laughing-gas or nitrous oxide, when the face is black, the veins turgid, the skin hot, the muscles irritable, and reflex spinal irritability is heightened.

Again, the blood-poisoning may be due to the action of some gas inhaled which interferes with or arrests the oxygen-carrying properties of the blood-cells. Sulphuretted hydrogen and carbonic oxide both appear to act in this way. The circumstances of the accident, the conditions under which the person was found, as well as some significant clinical appearances, already discussed by me, should facilitate the recognition of this source of coma. This blood change, if profound, is not recovered from.

Brain-poisoning and coma by anæsthetics and inebriants are usually detectable by the odour of the breath of the comatose poison.

You may occasionally feel a little uncertain as between apoplexy and dead drunkenness. We had an illustrative case the other day in our wards. A man who had been intoxicated by rum was admitted, and very profoundly comatose he was. No reflex movements were excitable; his face was cyanotic; there were gurgling râles in his throat, and I believe he might have died suffocated if I had left him in the position in which the nurse had placed him in bed, for he had a large tongue and uvula, with somewhat swollen and œdematous fauces; and as he lay on a flat bolster, with his head back, his tongue slipped back in his mouth, and nearly closed the opening of the glottis. Propping him up with a bed rest, and pulling his tongue forwards, his breathing quickly improved, and his face assumed a less blue colour. Still for some ten minutes I was unable to get any movement of either leg by tickling the soles of the feet, and the pupils were unequal, one rather smaller than the other, and both quite irresponsive to the stimulus of light. It was true he smelt of liquor, but he was quite properly admitted by the house-physician, since treatment and lapse of time alone could decide whether his coma was due to alcohol alone, or to disease *plus* alcohol. You may remember what I ordered in that case, as a piece of practice which is prompt, rational, and attended by no possible risks—the throwing up the rectum of a pint and a half of cold water, with a tablespoonful of common salt dissolved in it. It brought him out of his profound coma at once, for he asked for a night-stool almost directly afterwards. The stomach-pumping and belabouring with a galvanic battery of a comatose person, who may be the subject of gravescent apoplexy, belong to the surgery of the past, when active practice corresponded too closely with lynch-law-like punishment.

In every case of coma count the respiration, observe the quality of the breathing, and its ordinary effect upon the blood by the colour of the lips. Examine the pulse carefully for quality, frequency, regularity. Touch the eyeballs, examine the pupils for reaction to light, their condition—dilated, contracted, unequal, irregular; tickle the soles of the feet, to test what amount of reflex muscular action can be co-ordinated. The breathing in most states of coma is

heavy and slow; notice if it be stertorous, Cheyne-Stokes-like, wholly diaphragmatic, or if the intercostals act. Next take temperature in the axilla or rectum. A remarkably low temperature, four degrees or more below normal, betokens usually uræmic coma, acetonæmia, or grave concussion of the brain. After epilepsy, apoplexy, intoxication, the temperature is more often normal, or even slightly above normal.

Uræmic coma will again be separately distinguished most often by some slight œdema of eyelids or extremities, wax-like pallor, bronchitic sounds, very foul breath, smelling of beef-tea; a brown furred tongue, pearly conjunctivæ, and dilated pupils bespeak urea poisoning. Diabetic coma is indicated by oppressed noisy breathing, effected by abundant muscular effort, but attended by some lividity in evidence of impaired oxidizing changes at the pulmonary capillaries, of which we at present do not understand the exact cause.

In the coma that has succeeded an epileptic fit you may expect to find bruises, torn or dirtied clothes, indications of the tongue having been bitten.

Finally, the mode of recovering consciousness after intoxication differs much from what is observed in persons recovering from the coma that succeeds an epileptic fit. After intoxication I have noticed that while the sense of hearing is recovered soon, the lower attributes of mind, the sensorial instincts, reappear early, the individual who was comatosely drunk hears correctly before he sees correctly, and sometimes before he can stand. It is curious to notice the manner in which he repeats a word of your question over and over again, like a parrot, and perceive how some grotesque idea grows out of the jingle or jangle of a phrase mumbled over more or less thickly.

How differently do the mental faculties recover after brain concussion and commotion as after epilepsy. How the intellectually reduced "egomet" is in a dreamy state and staggers in his gait, hears questions put to him correctly, answers them articulately, apparently rationally, but having done so straightway forgets what he has said, cannot tell where he is or what he is or was doing. He is conscious of some confusion in his own memory, and shows often some high measure of judgment in his distrust of himself, and says, "I cannot recollect where I was going."

Intellectual wholeness or sanity lies outside to-day's lecture, and I mention this merely as a clue to past coma, whether from drink or cerebral commotion.

It remains for me to point out the distinctive features of opium coma. There is profound stupor, with closed eyelids, contracted pupils, upturned eyeballs; the face is pale, the skin cool, clammy; the forehead beaded with heavy perspiration; the limbs are lax, but, for a while, reflex motions are readily excited. The respiration now slackens, falls in frequency, perhaps, as I have seen it do, to as low an ebb as 6 per minute, the pulse remaining fair at 80. The coma now is very profound; you may prick, stimulate by galvanism, call, flick, stimulate by what means you please, little or no further purposive response is returned by co-ordinated muscular movements. The body will not walk; it is only dragged about, if the advice given has been to walk the man about. Next the lips get livid; the surface of the body colder; the breath is sobbing, and at long irregular intervals; the pulse hardly to be felt at the wrist, and death is imminent by asthenia or sudden failure of the heart's action. Now for what may you mistake this coma, and what may be most easily confounded with it? Apoplexy into the pons Varolii, since, as was pointed out long since by Dr. Wilks, who illustrated the fact by several examples of cases that had fallen under his observation, apoplexy into the pons is attended by great contraction of the pupils.

If, then, in any case of profound coma, with extremely contracted pupils, you suspect opium to be its cause, but have no corroborative fact, no laudanum bottle,

no opium-smelling substance, or mark of subcutaneous morphia syringing upon the body, or soot of opium-smoking inside the nostril to aid you, remember that the case may still be apoplexy into the pons, a source of coma not likely to be benefited either by bastinado, beating with towels, walking about, or all the extracts of coffee which can be pumped into the body at either extremity.—*Lancet*, Dec. 4, 1880.

Hospital Notes.

Galactocele; Incision; Cure.

Mrs. T——, aged eighteen, first came under Mr. PEARCE GOULD'S care in the out-patient room of the Westminster Hospital, on August 19th, 1878. She was a robust, healthy-looking young woman, who stated that two years before she struck her right breast against a chair, and three months afterwards noticed a small lump in the breast close to the nipple. She had been married fifteen months, and was confined of her first child in February. "Just a little milk came" in the right breast, but not enough to enable her to suckle with it. There was no pain in it, but as it felt different from the other, and did not secrete milk, she sought advice.

The left breast was well developed, with a good nipple, and secreted freely. The right gland was almost the same size as the left, but was almost completely occupied by a tense, rounded, fluctuating swelling, a little involuted mammary tissue being felt at the lower part; the nipple was flattened out by the swelling; the skin was not reddened, and there was no enlargement of the axillary glands. She was seen again on Aug. 23d, when the swelling was distinctly larger and "pointing," the contained milk being visible as a white spot in the centre of a red area. A small incision, radiating from the nipple, evacuated about half a pint of creamy fluid, and the sac completely collapsed; a horsehair drain was inserted, and the breast supported by a bandage of cotton-wool. A thick, milky discharge continued to flow from the wound for several weeks, and then gradually became thinner and less, and finally ceased in March, 1879. Extract of belladonna was applied over the breast at first, and later on pressure was employed. The fluid was examined microscopically, and found to be a clear liquid containing colostrum corpuscles, oil globules, and fine granules.

Remarks.—Lacteal cysts are not common. The history and appearance of this case left no room for doubt as to its nature. These cysts have been stated to arise from dilatation of the sinuses or large ducts, or from rupture of a duct and extravasation of milk, in which case they have been found to increase "rapidly and distinctly every time the infant sucks" Here this feature was not noticed, and the history of a previous injury and inability to suckle with the breast render it probable that there was obstruction to one, or perhaps more, of the lacteal ducts. Out of seventeen cases of galactocele recorded by Gross there had been a previous blow in two. It has been stated that such cysts never burst; this one "pointed" most distinctly, and at least threatened to burst.—*Lancet*, Nov. 27, 1880.

MONTHLY ABSTRACT.

Anatomy and Physiology.

The Cortical Centre for Movements of the Face.

In a recent issue of the *Progrès Médical*, M. BALLET records a case at La Salpétrière confirmatory of the views of Charcot and Pitres as to the centre for the movements of the facial muscles being seated in the lower third of the parietal and ascending frontal convolutions. It is certainly very rare to meet with cases of facial paralysis arising from limited central lesions. The patient in this case was a woman seventy-one years of age, who for some time had been the subject of senile tremors. She was admitted to the hospital with well-marked left facial paralysis, but with no impairment of motility of the limbs beyond a very slight degree of weakness in the left arm. Sensibility was unaffected. During the same day there appeared conjugate deviation of the eyes to the right, and the face became more strongly drawn to this side. The following day coma supervened, the eye and head being strongly deviated to the right, and death took place three days later. Post-mortem examination showed a recent clot weighing five grammes in the cortex of the right cerebral hemisphere, occupying the lower part of the ascending frontal convolution and bounding the fissure of Sylvius. On section it was found to have destroyed the inferior frontal fasciculus, and to have encroached upon the corresponding parietal fasciculus, without, however, reaching deeply enough to involve the central gray nuclei.' M. Ballet remarks that few cases hitherto published so clearly establish the seat of the psycho-motor centre of the face, the majority of such cases being those of facial paralysis associated with brachial monoplegia, with lesions extending beyond the limit assigned to the face centre. In this case, however, the hemorrhage and surrounding softening were limited almost entirely to the lower third of the ascending frontal gyrus, and had led to a facial "monoplegia" of the opposite side. The paresis of the arm, which increased slightly as the case advanced, was probably due to a slight extension of the hemorrhage, and to the pressure produced by this lesion upon the centre for the upper limb, which is in close contiguity to the facial centre.—*Lancet*, October 2, 1880.

Materia Medica and Therapeutics.

Indications of Anæsthesia by the Application of Chloroform to the Skin.

M. ALBERT HENOCQUE observes (*Gazette Hebdom.*, Nov. 10) that the Biological Society was deeply interested, at its meeting on the 13th inst., by a communication from Prof. BROWN-SÉQUARD, concerning certain profound modifications rapidly produced in the great organic functions and the properties of the nervous and muscular tissues, by the application of chloroform to the skin. The distinctness of the phenomena observed, their constancy, their absolute novelty, and the facility of their demonstration, are so many reasons for their successful reproduction in any physiological laboratory.

"Up to the present time Prof. Brown-Séquard has been able to expound the

results of more than sixty experiments, which I have assisted him in performing. The origin of these investigations was an unexpected fact which occurred during laboratory work. In order that a guinea-pig should be killed, upon which an experiment was performed some months before, it was placed under a bell into which ether had been poured. Anæsthesia taking place too slowly, a strong dose of chloroform was poured into the tube of the bell furnished with a sponge, so that the drops fell between the shoulder and the neck of the animal, *i. e.*, the epileptogenous region. It was immediately seized with a violent attack of epilepsy—a phenomenon never before observed in this guinea-pig, although it had had some epileptic predecessors. Prof. Brown-Séquard, wishing to at once investigate this fact, poured some chloroform on the same region of another guinea-pig, with the effect of inducing not epilepsy, but profound anæsthesia, together with a series of phenomena which have been many times verified since, and the most general type of which may be summed up in the following manner:—

"If we pour chloroform rapidly on the shoulder of a guinea-pig, a reflex contraction of the platysma myoides and subjacent muscles immediately appears; the animal at first tries to escape, but in a short time its respiration diminishes, its temperature descends, it staggers, and becomes torpid. It allows itself to be placed on the side or the back without attempting to re-assume a normal attitude; and then it falls almost suddenly into a state of anæsthesia, which may last for several hours, during which sensibility may disappear absolutely—the animal remaining inert, in a state of the most complete resolution, resembling that of anæsthetic sleep. If we operate on a young cat, the result is quite striking. It is well known that this animal is difficult to anæsthetize by chloroform, and that in a few minutes after the cessation of the inspirations it wakes up during a period of agitation somewhat alarming to those exposed to the attacks of the claws of the now furious animal. We can readily understand, therefore, the natural astonishment produced at the Biological Society, where any one might handle a young cat which the local application of chloroform practised an hour previously had plunged in such a sleep that the most vigorous pinching did not elicit any movement demonstrating the existence of sensibility. This condition, resembling shock, or the state of syncope following severe injuries or profound drunkenness, persisted in this animal for several hours, there being scarcely observable, from time to time, some automatic movements of the paws, seeming to announce an approaching awakening.

"Such are the most immediately striking phenomena which the local application of chloroform produces. We may add that certain differences are observed, according to the animal employed; but the capital result—the production of the most profound resolution of general anæsthesia—is obtained in the guinea-pig, the rabbit, the cat, and the dog. This fact already in itself is of great interest; but the investigation of other phenomena has exhibited results of considerable importance in physiology, some of these being so singular, or rather so novel, that it requires that they should be seen in order to be admitted. It will be readily understood that the series of phenomena produced by the local application of chloroform offers variations, but we shall not mention these in detail, it sufficing to trace their principal features; and, as will be seen, the facts observed are already rather numerous. Thus, the guinea-pig or cat, which we have left inert on our table, begins to show signs of muscular or nervous activity in the shape of tremors of the four paws. It raises itself in a staggering manner, taking the attitude of paraplegia or hemiplegia which it had presented prior to the anæsthesia; and two cats exhibited manifest signs of delirium. The animal gradually becomes conscious and recovers its activity. Sometimes there remains a state of hyperæsthesia, which may be very considerable, the skin becoming the

seat of a more or less active state of inflammation, if the dose of chloroform was considerable, and especially if the experiment had been repeated several times. The experiment may also prove fatal. Death may either supervene suddenly, as by sideration, or it may come on more slowly after a series of very characteristic symptoms have been observed, such as convulsions, epilepsy, diminution of the reflex faculty on the side on which the application had been made, pupillary contraction in the cat, or considerable dilatation in the dog. The respiration then becomes slower, being sometimes confined to the upper portion of the thorax; the diaphragm seems paralyzed, or at all events contracts no longer on one side; and, finally, the temperature becomes lower and lower; and the animal, if it be not sacrificed by opening the thorax, dies suddenly, generally without convulsions.

"It is then that the physiologist may verify a series of ultimate manifestations which accompany or follow death, and which trench upon most important problems in the investigation of the organic functions. The animal having been opened immediately after death, or just when this seemed imminent, the predominant characters in the aspect of the organs are found to be turgescence of the vessels of the intestines, of the spleen, and of the other viscera, and the red colour of the vascular arborescences; the aorta contains blood; the two ventricles are gorged with blood, and the blood of the vena cava is of a much less black colour than in the normal condition. In a word, we here find the characteristics of death in a state of syncope. The study of the excitability of the nerves and muscles presents results which are even far more interesting for the physiologist, and which may be thus summed up: 'The excitability of the muscles and nerves of the limbs and trunk, as well as the excitability of the nerves to mechanical action and galvanic currents, are modified.' Not only is a relatively very feeble galvanic current sufficient, Prof. Brown-Séquard observes, to bring these parts into play, but we find that the persistence of this irritability after death is much greater than in healthy animals killed by opening the thorax. In the guinea-pig especially, the persistence of excitability in the sciatic and brachial nerves has been met with three or four times greater than in guinea-pigs not submitted to the action of chloroform—the excitability lasting an hour and a quarter instead of from twenty to twenty-five minutes, as is habitually observed. Phenomena of not less importance than the preceding have been discovered from observation of the galvanic excitability of the phrenic nerves and various portions of the diaphragm. To use Prof. Brown-Séquard's own words, 'In two dogs and in several guinea-pigs, after opening the thorax, the phrenic nerve of one side was found to have lost its excitability, completely in one case, and almost completely in others. The corresponding half of the diaphragm also underwent a notable diminution of irritability, which only continued the fourth or the third of the ordinary period of persistence of this property of the muscle after the thorax has been opened. It is the phrenic nerve and half of the diaphragm of the opposite side to that of the application of the chloroform that thus become inhibited and paralyzed, not only as regards their action which depends on nerve-cells, but also their property of tissue.' In other words, the phrenic nerve of the opposite side to the application of chloroform, in certain cases, presents a diminution, or even a cessation, of its galvanic irritability. Excited by strong, medium, or feeble induced currents, the phrenic nerve no longer causes the contraction of the half of the diaphragm which corresponds to it, or a comparatively very strong current is required to produce contractions. Finally, in one case, which we can never forget, the lateral half of the diaphragm, situated on the opposite side to that of the application of the chloroform, was unexcitable by the strongest galvanic current that we are in the habit of using—the muscular excitability having disappeared. Truly a singular phenomenon, since it is the first occasion in which

the loss of muscular excitability resulting from a remote irritation has been observed.

"We will not insist upon the peculiarity of this crossed action on the phrenic nerve and the diaphragm, because we are not about to put forth on this occasion a complete theory of these phenomena. Can such a theory, indeed, be advanced already? I should feel greatly disposed to answer in the affirmative, and to indicate the fundamental conclusions flowing from it, did I not fear trenching on the reserve necessary with regard to Prof. Brown-Séquard, in a matter still the subject of daily investigation, and which will shortly form the subject of his public lectures. Still, even at present, I may sum up the theoretical outlines characterizing these phenomena. We have here to do with one of the phenomena connected with inhibition; that is, the arrest of function. A remote action takes place, through the skin, on the nervous system. Such inhibition may go on to simple syncope, syncope with asphyxia, or finally to syncope with arrest of the exchanges. And, in fact, the diminution of temperature, the modifications in muscular and nervous excitability, the presence of red blood in the veins, of blood in the aorta—this condition of syncope, resembling at the same time anæsthetic sleep, the coma of drunkenness, sideration, or the state of shock, presents all the characteristics assigned by Prof. Brown-Séquard to the group of inhibitory phenomena which he has described under the name of 'arrest of the exchanges.' We shall have occasion to return to these theoretical considerations and their development. At present it suffices to have exhibited a series of facts possessing an importance of the first order. These facts can be reproduced, for their verification is easy; nothing but an animal and a bottle of chloroform being requisite for the principal features. But it is of importance to avoid a cause of error arising from the absorption of the chloroform by the lungs. Such a complication may be avoided by applying to the mouth of the animal the muzzle which is generally employed in chloroforming, but on this occasion terminating it with a caoutchouc tube sufficiently long to avoid the respiration of the vapour of the chloroform. I may add, however, that this precaution is not indispensable, for Prof. Brown-Séquard has frequently found that the respiration of the vapours of chloroform, which may take place during these experiments, does not induce any sensible modification of the symptoms. More than this, it has been observed that the injection of chloroform as an enema produced in a dog no phenomena analogous to those described, and which yet were later manifested in this same dog as a consequence of the application of chloroform to the skin."—*Med. Times and Gazette*, Nov. 27, 1880.

—

The Use of Martin's Elastic Bandage.

Dr. PAUL BRUNS, of Tübingen, is a warm advocate of the employment of the India-rubber bandage, and asserts unhesitatingly that Martin's method of treating ulcers of the leg is the best and most effectual that has hitherto been practised. Seventeen cases of ulcer thus treated are reported by this surgeon (*Berliner Klinische Wochenschrift*, Nos. 25, 26, 1880), in order to prove the certainty and simplicity of the method. Not only does this treatment obviate the necessity of prolonged rest and of serious neglect of work, but its duration until complete cicatrization of the ulcer seems in most cases to be shorter than that required for other methods of treatment in which the patient is kept in bed.

The employment of the rubber bandage has been found very useful by the author in the treatment of other affections of the lower extremities. Cases are referred to which show its utility in simple chronic eczema. It was found that, in cases of long-standing ulceration of the leg with eczema and infiltration and hypertrophy of the surrounding skin, the bandage acted very favourably on the

general condition, and that, as the ulcer healed, the scaly and thickened skin became smooth, clean, and soft. The application of caoutchouc in the treatment of the different forms of eczema was long ago advocated by Hebra, but it was used by this physician simply as a water-proof material, with the object of raising the temperature of the affected surface, and of macerating the epidermis by retained perspiration. Martin's bandage not only fulfils these indications, but also exerts elastic compression of the skin, an action of much importance and utility for effecting absorption of infiltration and controlling any varicose condition of the superficial veins. Dr. Bruns is of opinion that this treatment is likely to be attended with very good results in cases of obstinate and relapsing chronic eczema of the lower limb, due to disturbance of circulation and nutrition. The advantage of applying compression in cases of varicose dilatation of veins, associated with infiltration of the cellular tissue, is universally recognized, and hence the common use of elastic bandages and stockings. The use of Martin's bandage has this advantage, that the degree of compression may be readily and easily controlled, and that the rubber is a durable material. There is frequently difficulty in procuring a well-fitting stocking; and with both stockings and the ordinary elastic bandages the material is apt to lose its elasticity, and so to become useless. Dr. Bruns states that he has attained very striking results from the use of the rubber bandage in the palliative treatment of varicosity. The patient no longer complains of pain on standing or walking, and the sensation of heaviness and weariness is absent even during active labour. One case is quoted in which a good result was obtained, although on the first application of the bandage the varix was on the point of bursting. Cases have been reported by Martin and others in which a radical cure of varicose veins had been attained by the prolonged employment of the rubber bandage, but Bruns is of opinion that such a result is hardly to be expected in instances of varicosity of extreme degree.

The employment of the rubber bandage is also indicated, Dr. Bruns thinks, in cases of elephantiasis of the lower extremity. In slight forms of this affection good results have been attained through elevation of the affected limb, and firm and forcible application of flannel bandages. The thickness of the limb has thus been reduced even to the normal size, but usually relapse occurs after the patient has ceased to maintain continuously the horizontal position. A double advantage might fairly be expected from the employment of the rubber bandage. In consequence of the compression of the limb being more regular and forcible, the duration of the treatment might be shortened, and the period of necessary continuous rest in the horizontal position reduced; and, besides, the habitual wearing of the bandage might prevent the occurrence of relapses. In two cases, treated by Dr. Bruns, of chronic ulceration of the leg, associated with thickening and degeneration of the skin, of the nature of elephantiasis, this latter condition was completely removed after the application of the rubber bandage, although the patients were not confined to bed.

The rubber bandage, on account of the perfect elasticity of its material, is the most fitting of all known agents for compression in cases of joint-disease. With regard to the indications of its employment, Dr. Bruns states that he has attained excellent results from its employment in cases of articular distortion. He has applied the bandage in cases both of recent and of chronic distortion of the wrist, knee, and ankle. In recent cases the swelling caused through intracapsular effusion is kept within bounds, and in late stages absorption is accelerated by the compression of the bandage. By continuous wearing of the bandage, which serves as an effectual support to the affected joint, the utility of the limb is restored in a short time.

In two cases of hæmarthrosis recently under the care of Dr. Bruns, and treated

by the application of the rubber bandage, the extravasated blood was absorbed in a much shorter period than one might expect to suffice with the use of an ordinary bandage. In a case of fracture of the patella with hæmarthrosis, also treated by the rubber bandage, the abundant effusion of blood was absorbed within eight days. As an agent for bringing together and fixing the fragments of a broken patella, this bandage acts more effectually than strips of plaster.

Dr. Bruns has not hitherto had any experience of the use of the bandage in the treatment of acute hydrarthrosis, but he refers to cases reported by Byrne (*Lancet*, 1879, p. 645), in which striking results were attained from its employment in acute synovitis. The rubber bandage is particularly useful in cases of hydrarthrosis. The main difficulty in the treatment of this very troublesome affection consists, not in procuring absorption of the effusion, but in the extraordinary tendency to relapse, which usually occurs sooner or later after use of the affected limb. The bandage has been applied by Dr. Bruns in three cases of chronic hydrarthrosis of the knee with very promising results, and by its long-continued application the tendency to relapse seems to have been permanently obviated. In one case the effusion was absorbed in two days on forcible compression, and in the other two cases in four and six days on gradual and slight compression. The bandage in each case was then worn night and day for two months. No relapse occurred in two of these cases after an interval of four months, and in the third case after one year. In the use of the elastic bandage in cases of this kind, Dr. Bruns thinks it well to apply a weak and continuous rather than forcible compression. The application of forcible compression demands some care when the elastic bandage is used instead of a flannel bandage. The former, even when not applied very firmly, exerts through its great elasticity an equable and permanent compression, and acts with much greater effect than a firmly applied inelastic roller. Instead of reducing the intra-articular effusion through forcible compression of the joint, Dr. Martin removes the fluid by aspiration, and then applies the rubber bandage, which is worn night and day for at least six weeks. A similar treatment has been carried out with much success in cases of prepatellar hygroma.

The rubber bandage, as it can readily be cleaned and disinfected, is a better agent than the bandage made of elastic webbing for producing artificial anæmia of a limb before operation, and also for retaining in position antiseptic dressings. When applied over a gauze dressing it insures absolute occlusion, and at the same time exerts equable compression, a condition favourable, in many cases, to healing of a wound by first intention.—*London Med. Record*, October 15, 1880.

Medicine.

Hemorrhagic Diathesis, in relation to Leukæmia and Allied Conditions.

Professor MOSLER, in a contribution to the *Zeitschrift für Klinische Medic.* (Band i. Heft 2, p. 265 *et seq.*), discusses the relation of the hemorrhagic diathesis to the considerations which should guide the surgeon in undertaking operations in cases of leukæmia and allied conditions. At the beginning of his paper, he relates the history of the disease in a patient, aged 40. After this patient had suffered from various diseases, the last of which was an obstinate anomalous intermittent fever, a splenic leukæmia developed itself. It was diagnosed in 1877. The relation of the white to the red blood-corpuscles was as 1 to 5. After a long treatment, the patient (who was a medical man) desired that splenotomy

should be performed; but Dr. Mosler, as well as Dr. Péan, of Paris, dissuaded him from the operation. The patient suffered, at the same time, from old hæmorrhoidal patches, and an inflammation had developed itself around the anus, without any distinct cause. When the abscess was opened, free bleeding occurred, which, notwithstanding all the means applied, lasted for several days. There was severe collapse. After an application of the thermo-cautery, the bleeding ceased on the fourth day, but recommenced subsequently to the evacuation of hard fecal masses. The patient could not be chloroformed, on account of his extreme weakness, and for the same reason, the thermo-cautery could not be applied; digital compression was employed, and pressure was made on the wound, from one to nine o'clock in the evening, a tampon of cotton, saturated with chloride of iron, being pressed on the wound. At the end of eight days more the bleeding recommenced, and was arrested after digital compression for an hour and a half. The patient recovered slowly; but four months afterwards death occurred, in consequence of retroperitoneal hemorrhage, the source of which could not be ascertained at the *post-mortem* examination.

The patient attributed his illness to the obstinate intermittent fever, as well as to excessive anxiety and mental exertion. The pains from the sternum were most important in the symptomatology of the medullary leukæmia. The severe bleeding, after slight operative proceedings, afforded evidence that account must always be taken of the hemorrhagic diathesis, in relation to leukæmia. In such circumstances, Mosler indicates solid ground for rejecting splenotomy. He relates short notices of twelve other cases, in which bleeding complicated the disorder; most frequently bleeding from the nose, but also from the stomach and bronchi. In 150 cases collected by Gowers, there were hemorrhages in 80 cases.

Mosler observes, that the operation of splenotomy can only be tolerated when there is a perfectly normal condition of the other organs; when the splenic tumour is not extensively adherent, and is of hard, firm consistence; and when hemorrhagic diathesis is absent. This diathesis shows itself, not only in the later stages, but sometimes, also, at the commencement of leukæmia, and is especially liable to complicate hypertrophy of the spleen. Mosler considers that the hemorrhagic diathesis, which always shows itself in pseudo-leukæmia, where there is no distinguishable increase of the white blood-corpuscles, depends on the poverty of the blood in functionally active red blood-corpuscles, and on the weakness and friability of the arterial walls, through deficient nutrition.—*Lond. Med. Record*, Nov. 15, 1880.

Cold Baths in Cerebral Rheumatism.

Dr. Woillez has read an able paper upon this subject at the Academy of Medicine (*Union Méd*, October 14). After adverting to the former fatality of the disease, he states that since 1870 it has become more and more evident that it may almost always be successfully treated by the application of cold, the cold bath at 20° C. (68° F.) being the form of using it which he prefers, repeating it every three hours, until the cessation of the delirium and the reappearance of the swelling of the joints. Generally the cessation of the cerebral accidents only lasts for a short time after the first immersion, but gradually increases in duration after the subsequent ones, a refreshing sleep succeeding the period of agitation. When the baths cause shivering they should be discontinued. In no instance in which they have been employed have they given rise to mischievous effects; and even when, owing to their defective application, they have not prevented death, they have prolonged life. They may be prescribed under the following conditions: 1. When to the delirium there are added diminution or disappearance of

the swelling of the joints and a temperature of 40° C. (104° F.) and above. Under this combination, the baths may be said always to succeed in procuring recovery at all periods of the disease, whether there be only delirium, coma, or imminence of death. 2. We should have recourse to them if with the delirium there is no diminution in the articular symptoms, but the hyperthermia exists. 3. The bath should be replaced by revulsives when merely delirium prevails, the articular disease pursuing its course, and no hyperthermia being present. Dr. Woillez observes that it is an error to regard the hyperthermia as the sole indication for the employment of the cold bath, the articular fluxion requiring also to be taken into consideration, since, in a certain number of cases, revulsive treatment having caused this fluxion to reappear, a cure has resulted. Although so strong an advocate for the cold bath in cerebral rheumatism, he does not regard it as opportune in all general diseases with high temperature, and especially in typhoid fever, in which he considers it as ineffectual and injurious.—*Med. Times and Gaz.*, Oct. 23, 1880.

—

Recovery from Symptoms of Organic Brain Disease.

Dr. HUGHLINGS JACKSON at a late meeting of the Medical Society of London (*Lancet*, Oct. 23, 1880) read a paper on a case of recovery from symptoms of organic brain disease. The case was one of supposed hysteria, double optic neuritis with nearly complete blindness, severe headache, no vomiting, loss of smell; no deafness; reeling gait; absence of patellar-tendon reflex; doubtful lightning pains. Recovery under mercurial inunction, except of anosmia and absence of patellar-tendon reflex.

The patient was a well-nourished woman, twenty-two years of age, admitted into the London Hospital on Dec. 22d, 1879. Menstruation was regular; there was no evidence of syphilis. In August, 1878, she was run over by a cart, her legs being injured above the ankles. In May, 1879, she went into service, and was quite well except for a "weakness in her legs." This "weakness" increased, and two days before admission she could not stand at all, and took to her bed. During the week before admission there was a weakness of the right arm, which would "go and come;" afterwards "pins and needles" in this limb, and then weakness of the left arm set in. Her sight began to fail two or three weeks before admission.

Symptoms of local gross organic disease: (*a*) double intense optic neuritis (with mere perception of light); (*b*) intense headache, from the misery of which she was silent and very quiet. On her recovery it was ascertained that smell was entirely wanting. She averred that she used to smell well before her illness. Dr. Jackson was doubtful whether anosmia was in her case a localizing symptom or not. It may have been owing to pressure, direct or indirect, on the olfactory bulb; or, what is quite hypothetical, to an olfactory neuritis.

Localizing symptoms: (*a*) absence of patellar-tendon reflex—an exceedingly important symptom, especially as her gait was abnormal, without paraplegia. The reflex was still absent when she left the hospital on March 25th. It may have been so long before she had the other symptoms, but of this nothing could be learnt. (*b*) Pains in limbs. At one spot a little above the left knee she had occasionally a dart of sharp pain, followed by a dull aching; it would come and go. She had no severe pain except in the head. It could not be averred that the pains were those characteristic of posterior sclerosis. (*c*) Reeling gait. This was noted carefully. When admitted she could scarcely walk at all, and not without help. Her gait then was not like that of locomotor ataxy. As she improved a little it could be better analyzed. It was evidently a reel—a drunken-like walk. Apparently she had good power in her legs, and, using popular

language, though inexact, there was "disorder" of coördination without "paralysis." (*d*) Other symptoms. There was some slight weakness of the left arm, with a slightly feeble grasp. These symptoms were very slightly marked. Some tenderness of the lower part of the spine was found. No very local tender spinal spot was revealed, either by the application of a hot or cold sponge, or by manipulation. There was no spinal curvature, no atrophy of any muscles, no defective sensation, and no vesical trouble of any kind.

Progress: rapid recovery. Iodide of potassium was at first prescribed in doses of five grains three times a day; but on January 4th mercurial inunction was ordered in addition. The dose of the iodide was smaller than that usually given in such cases. Under this mixed treatment she rapidly improved. From what was practically blindness she became able to read on January 26th No. 1 of Snellen at six inches with her left eye, but with the right only No. 3. On the day of her leaving the hospital, March 23d, she could read No. 1 very easily with her left, and with slight difficulty with her right eye. Practically her sight was quite good. She felt well, and except that the patellar-reflex was still absent, and that she could smell nothing, she was considered to be free from symptoms.

Dr. Hughlings Jackson then considered the case from several points of view. He referred to cases of recovery from symptoms induced by tumour of the brain; cases in which after little illness there was post-mortem evidence of tumour. He discussed also the question of syphilis, pointing out that a syphilitic tumour sometimes gave rise to symptoms similar to those produced by glioma or other "foreign body." He did not think that the mere fact of his patient's recovery under anti-syphilitic treatment necessarily overruled the conclusion that the intra-cranial disease was syphilitic. He spoke of the importance of the routine use of the ophthalmoscope, both as sometimes negativing the diagnosis of hysteria, and also as leading to early treatment.

Dr. ALTHAUS said the great difficulties in diagnosis of brain disease could be traced to two classes of cases—viz., those in which coarse lesions, as hemorrhage, softening, abscess, atrophy, and tumours were found after death, yet no symptoms had existed during life; and others in which the gravest symptoms, pointing to severe organic changes, were observed, and the patients recovered under treatment. He alluded to hemi-anæsthesia occurring from disease of the posterior part of the internal capsule, and the same affection as occurring in Charcot's hystero-epileptic women, in whom the disturbance was purely functional. He also related a case resembling in many points that described by Dr. Jackson, and in which he had made the diagnosis of tumour in the right cerebral hemisphere. In this case the administration of mercury and iodide of potassium led to recovery, although the patient had never shown any symptom of syphilis.

Dr. BROADBENT remarked upon the interest and value of the communication, the case affording Dr. Jackson an opportunity for the refinements in diagnosis which he had placed so clearly before the society. He had, no doubt, seen many instances of recovery from far more serious symptoms of organic disease of the brain, as had Dr. Broadbent and others; and in this case the symptoms formed a distinct category, indicating the seat of the disease, and no one would doubt his diagnosis of a coarse lesion in or affecting the cerebellum. Dr. Broadbent thought the course of symptoms and rapid recovery were best explained by supposing the lesion to be syphilitic, and he cited a case of a young woman, recently under his care, suffering with headache, vomiting, convulsions, double optic neuritis, and paralysis of the left third nerve. She had certainly not acquired syphilis, but there was a scar on her forehead of a suppurating node (which had not healed until she took iodide of potassium), and no doubt she was the subject of hereditary syphilis. She rapidly recovered under large doses of the

iodide; but about twelve months after was readmitted with paralysis of the right sixth and seventh nerves. He had also under treatment a case of hemiplegia in a young man, obviously due to inherited syphilis. The loss of patellar-tendon reflex was presumptive evidence of syphilis; for, as Dr. Gowers had recently stated, probably 75 per cent. of cases of locomotor ataxy were due to syphilis; and this case might be one of incipient ataxy. With regard to optic neuritis, he confirmed from many cases the fact so often insisted upon by Dr. Jackson, that this may exist without noticeable affection of sight; and in the present case he was inclined to attribute the blindness to pressure on the optic tracts or nuclei by the disease in the cerebellum. He held the view that optic "neuritis" was really ischæmia, due to strangulation of the nerve and its vessels just behind the eye-ball, by effusion into its sheath; and he believed the neuritis, with numerous hemorrhages (not, of course, the ordinary albuminuric retinitis) seen in some cases of renal disease, had the same causation.

Dr. DOWSE asked whether Dr. Jackson had met with the absence of patellar-tendon reflex when no actual posterior sclerosis existed; and said that in his opinion the phenomenon might be due to inhibition.

Dr. JACKSON replied in the negative.

Lead-Paralysis.

KAST (*Centralblatt für Nervenheilkunde*, April, 1880) has made some experiments with a view of testing the accuracy of Mason's statement (*American Journal of Med. Sciences*, 1877). The latter said that the electrical reactions in frogs dipped in weak solutions of lead-salts proved the presence of degenerative atrophy in their nerves and muscles. The author's results were in direct opposition to this; in no case could he find any trace of the reaction of degeneration. Kast adds a few remarks on a case of saturnism, in which the muscles of the left thenar, though functionally almost normal, did not react to faradism directly or indirectly applied. The anodal closure contraction was obtained much more readily than the cathodal, and presented the typical sluggishness and persistence noticed in cases of degenerative atrophy.—*London Med. Record*, Oct. 15, 1880.

—

Neurotic Atrophy.

Professor VIRCHOW had the good fortune this summer to be able to demonstrate to the Berlin Medical Society two cases of the rare affection to which he gives the above title. Without entering into much detail, we think it may not be unprofitable just to ask attention to the principal points in each case, and to the view Virchow takes of the disease. The first case is remarkable as having been under Romberg's care more than twenty years ago, when Virchow saw it and made notes of it. It was chiefly on it that Romberg based his theory of the tropho-neuroses. The patient, a man named Schwahn, is now aged forty-two, and the onset of his disease dates from his ninth year, when he is believed to have had a severe tonsillitis accompanied with swelling and abscess in the left cervical and submaxillary region. Whether *post hoc* or *propter hoc*, the whole left side of the face has suffered more or less atrophy, especially along the course of distribution of the branches of the fifth nerve. The left side of the face is smaller than the right, the affection having begun during the time of active growth of the bones. The difference between the two halves of the under jaw is particularly marked, the chin having been pushed over to the left some way beyond the middle line by the superior growth of the right half of the jaw. The tongue is also much atrophied on the left side, but, curiously enough, only in its middle portion, and not at the root or tip. A very striking feature in the case is the

condition of the bloodvessels. While the surrounding tissues from the skin inwards are wasted and shrunken, the veins and arteries of the part appear absolutely unchanged, the larger even projecting above the surface of the skin. By stimulating the part they dilate as in a normal individual; in fact, they appear to be altogether excluded from the surrounding atrophy; and Professor Virchow expresses his opinion that any idea of the atrophy being dependent on vaso-motor influences must be entirely given up. Again, the sensibility of the part shows scarcely any deviation from the normal, nor can there be said to be any paralysis of its muscles; what remains of them contracts, but their nutrition has been terribly reduced. The most striking feature of the affection, in Virchow's eyes, is the curious and inexplicable way in which the disease leaves parts of a nerve-trunk intact, and skips as it were from one section to another. It is common to all this class of cases. He says—"This fact has a special additional interest for me, owing to the possibility of the occurrence of analogous processes also in the interior of the body, so that perhaps many changes in internal organs, which we are inclined to interpret quite differently, should be referred to similar alterations of the nerves to those met with here."

Before dismissing Schwahn's case we should say that Professor Virchow has not been able to convince himself, after comparing the patient's present state with that described in his notes taken twenty-one years ago, that any material alteration has occurred in the atrophic parts; in fact, he regards the disease as having long ago become stationary. The point is an important one, as many authors regard the affection as inevitably progressive.

The second case exhibited by Professor Virchow was that of a woman, aged forty-one, also with atrophy of the left half of the face, but without atrophy of the bones, as she was twenty-five years old when the illness which appears to have excited the atrophy occurred. She is the subject, however, not only of an atrophy involving the branches of the fifth nerve, but also of one which, commencing in some of the dorsal cutaneous nerves of the scapular region, affects the musculo-spiral nerve from its origin in the axilla, passing down the arm and forearm, and attaining its greatest development in the region of the radial nerve in the forearm and hand. The appearances are practically the same as in Schwahn's case: thinning of the skin, absolute atrophy of the subcutaneous adipose tissue, intense atrophy of the muscles without paralysis, great prominence of the bloodvessels, and no marked alteration of sensibility. The patient sometimes suffers from stabbing pains in the eye and arm, as well as from numbness in the atrophic region. She attributes the disease to an attack of what was probably erysipelas following her confinement, but it also appears that a fall on the back of the head in the street, which occurred about the same time, may have had some connection with it. Professor Virchow has seen a third case in a girl of eighteen, where the atrophy was supposed to have followed dental inflammation when she was twelve years old. In many of the recorded cases, however, no cause for the atrophy could be assigned.

As to the exact nature of the disease, of course nothing definite is known, but Virchow distinctly lays it down that the affection of the nerves is here peripheral, and not central. He believes, however, that a primary process being once set up in the nerve-trunks, owing to inflammation of the surrounding tissues, may then extend upwards to the spinal and basal cerebral ganglia. If so, the disease has a certain analogy to herpes zoster. The way in which the nerve districts are unequally attacked finds a parallel also in the various forms of lepra and in morphœa, though we are equally unable to explain it in these diseases as in Virchow's "circumscribed neurotic atrophy." "What we want," says Virchow, "to clear matters up is an adequate anatomical examination of the nerves and central or-

gans in one of these cases, so that we may know for certain what takes place. There are few phenomena in the field of nerve pathology which excite such a desire to explain them as the affection before us, and in which nature seems to perform such a test experiment for the isolation of the different kinds of fibres in the peripheral nerves."—*Med. Times and Gaz.*, Oct. 9, 1880.

—

An Epidemic of Hystero-Epilepsy.

A recent outbreak of nervous disturbance in Italy, which has been described in the *Annales d'Hygiène* by M. LÉON COLIN, indicates that the conditions which gave rise to some of the most remarkable epidemic phenomena of the Middle Ages are not yet extinct in the country in which they were then chiefly prevalent. On Dec. 11, 1878, the governor of the district of Tolmezzo informed the Prefect of Undine that for three months some forty females, living in the commune of Verzegnis, had been attacked by religious mania. In consequence, Drs. Franzolini and Chiap were delegated to examine the outbreak. From their report it appears that the first case was in the person of a woman named Marguerite Vidusson, who had been the subject of simple hysteria for about eight years. In January, 1878, she began to suffer from convulsive attacks, accompanied by cries and lamentations. She was regarded as the subject of demoniacal possession, and on the first Sunday in May was publicly exorcised. Her affection, however, increased in severity; the attacks were more frequent and more intense, and were especially provoked by the sound of church bells, and by the sight of priests. Seven months later, three other hysterical girls became subject to "convulsive and clamorous" attacks. Here, again, an attempt was made to get rid of the supposed demon. A solemn mass was said in the presence of the sufferers, but was followed only by a fresh outbreak. At the time of the visit of the delegates eighteen were suffering, aged from sixteen to twenty-six years, except three, whose ages were respectively forty-five, fifty-five, and sixty-three years. Similar symptoms had also appeared in a young soldier on leave in the village.

During the attacks the patients talked of the demon which possessed them, stated the date on which they were seized by it, and the names of the persons who were possessed before them. Some boasted of being prophetesses and clairvoyants, and of having the gift of tongues. In proof of the latter they pronounced incomprehensible sentences, which they affirmed to be Latin or French. In all the sound of church bells caused attacks, and religious ceremonies appeared not only to aggravate the disease in the sufferers, but also to cause its extension to those not previously attacked. The reporters referred the outbreak to pre-existing hysteria, aggravated by the fanatical zeal of certain preachers, and to the frequency and exceptional impressiveness of the religious services which were being held as a means of cure. Their effect was to recall to the memory of the hysterical women the legends of demoniacal possession and of sorcery, and the exorcism of the priests deepened their conviction as to the nature of the affliction. Dr. Franzolini draws special attention to certain old establishments long of repute for the efficacy of the exorcisms practised at them. He cites especially the sanctuary of Clanzetto, an odious vestige, as he terms it, of the barbarism of the Middle Ages.

M. Colin points out that the soil was particularly favourable for the development of an epidemic of this nature. The population of Verzegnis is backward in education, and most superstitious, and functional nervous diseases are common among them. Dr. Franzolini has, however, ascertained that they possess a practical immunity from alcoholism and from pellagra, and also from diseases due to general insanitary conditions. He appears to be inclined to ascribe some share

in the production of the disease to an obscure pathological influence derived from the French race, since he notes that the inhabitants pronounce the letter "r" as it is pronounced in France, and not as in Italy—the suggested inference from this circumstance M. Léon Colin is naturally unable to discern. It appears, further, that the inhabitants of the village are a good deal cut off from intercourse with the adjacent country in consequence of comparative inaccessibility, and the frequent interruption of communications by storms and floods. Moreover, craniometric observations on twelve of the inhabitants seem to show that the brachycephalic form of skull predominates, and that the development of the cranium is slightly below the average.

M. Colin points out, with much truth, that the relative sequestration of the inhabitants of a town must tend to favour the spread of such a nervous malady, if it does not assist in its production. The reciprocal impressions of the inhabitants are little varied, and hence, in spite of differences in age and social position, the members of the community come to bear a close mutual resemblance in psychological constitution. Consanguineous marriages will be common in such a population, and will contribute to the deterioration of the masses, and to the development of any common morbid predisposition. If such a predisposition results, in one individual, in actual disease, many others are probably not far from the same morbid state, ready to undergo fuller development by imitative contagion.

The epidemic at Verzegnis has proved extremely obstinate. Since the commissioners visited the place, new cases have occurred, which have rendered energetic measures necessary—even a military occupation of the district (!)—while seventeen of the "possessed" have been compulsorily removed to the hospital at Udine. Such an epidemic constitutes a rare event in modern Europe, but it reminds us closely of some historical epidemics with which all are familiar. Even in our own day, in some backward races, as of Norway and New Caledonia, similar outbreaks have been observed.—*Lancet*, Oct. 16, 1880.

—

Puncture in Pleural Effusions.

GOLTDAMMER, at a recent meeting of the Berlin Medical Society (*Berl. Klin. Wochenschrift*, Nos. 19 and 20), laid before the members certain results of his rich experience at the Bethany Hospital with regard to this question. He has operated in all on 123 cases, and performed 200 punctures on them. Of these 123 cases, 19 were cases of purulent exudation, 49 cases of primary pleurisy with sero-fibrinous exudation, and 55 were cases of secondary exudation and transudation (in phthisis, pneumothorax, typhus, tuberculosis, carcinoma, and hydrothorax, and in affections of the heart and kidneys). In purulent exudations, Goltdammer thus far considers incision to be indicated without exception; he makes the opening generally at the angle of the scapula, and, at the same time, performs resection of a piece of rib. For the first time, on the 18th February, shortly before his communication, he had employed the puncture with antiseptic washing out, recommended by Baltz in a case of purulent exudation, and was very well satisfied with it. The exudation did not collect again, and at the end of seven weeks, the patient recovered with the lung perfectly expanded. Goltdammer divides sero-fibrinous exudation of primary idiopathic pleurisy in otherwise healthy infants, into two groups: the first includes the abundant effusions, which displace the whole contents of the thorax, the heart, and liver; in the second group, he reckons the smaller and average effusions. In the first group, in which he counts 22 of his 49 cases of sero-fibrinous exudation, puncture had the most excellent results. In several cases (8 times) one puncture

succeeded in giving direct impulse to resorption; diuresis increased, and in from nine to fourteen days the residual fluid disappeared. In seven cases, the puncture needed to be repeated. It may be considered a rule that the level of the fluid rises a few days after the puncture in the intercostal spaces; this Goltdammer explains partly by the return of the displaced organs to their normal position. Puncture must not be delayed until dyspnœa becomes dangerous, but must anticipate such a condition. The degree of the phenomena of displacement determines the period for puncture. Fever does not contra-indicate it; it usually disappears after a few days. The author evacuates the fluid to the extent of from 1½ to 3½ litres with a trocar, protected against the admission of air, and generally in the median line. In the small and median effusions, he makes the puncture with Dieulafoy's aspirator with capillary canulæ. Delay of absorption, that is to say, when, about eight days after the cessation of fever, no resorption could be ascertained—indicated puncture in 27 cases. In these cases usually from 500 to 600 cubic centimetres were evacuated, sometimes a litre. All the cases of sero-fibrinous effusion recovered, both those with abundant and those with scanty effusion. No suppurative change in the exudation occurred in any case. The cases of pleurisy treated with puncture in no case gave rise to any considerable retraction. In cases of secondary exudation, as well as of transudation, he finds an indication for puncture principally in dyspnœa, and has always seen some, and often a very considerable, palliative result; and occasionally in heart disease, a considerable improvement in the primary affection. In pneumothorax, also, the removal of the fluid exudation relieves the patient. On five occasions, he found the effusion serous and not purulent. He aspirates with Dieulafoy's apparatus, puncturing in cases of slight exudation at the seventh or eighth intercostal space below the angle of the scapula, in more considerable effusions at the fifth or sixth space in the axillary line. Absolute cleanness of the instrument, of the place of puncture, etc., is to be looked after with the greatest care. Finally, he refers to the disagreeable incidents and occasional dangers of the method. Laceration of the lung by aspiration he considers to be impossible, with a little care; so soon as dragging pains occur, or the well-known paroxysms of coughing, induced by the re-admission of air to the collapsed part of the lung, the aspiration is stopped. Suppurative change of the exudation is also unknown, according to Goltdammer's experience, when the operation is performed carefully. He has seen such a thing once only, in a case in which the flow of fluid through the trocar was stopped, and in which he drew out his needle to clear it, and thus introduced germs of infection (drops of oil, etc.). In cases in which this suppurative change is believed to have occurred through puncture, either there has previously existed a slightly turbid exudation, or germs have been introduced, through unclean instruments. In a correctly performed puncture, sero-fibrinous exudation is never changed to a suppurative one.—*London Med. Record*, Oct. 15, 1880.

—

Traumatic Hœmothorax.

The following are the general conclusions given in a recent work by Dr. CH. NÉLATON, of Paris (*Des Epanchements de Sang dans les Plevres consecutifs aux Traumatismes*, Paris, 1880): 1. Effusions of blood into the pleura result either from a lesion of the vessels of the thoracic wall, or from wounding of the intrathoracic vessels. In the latter case, the pleural hemorrhage is usually derived from the vascular divisions accompanying bronchi of the second and third order. 2. Thoracic aspiration favours the flow of blood. The bleeding is speedily arrested by the accumulation of blood in the pleura. 3. The blood effused into the chest coagulates immediately and throughout almost its whole mass, and so

becomes divided into two portions: coagulum and serosity. 4. If the effusion be not very abundant, the serosity is reabsorbed by the third or fourth day; and when the phenomena of inflammatory reaction supervene, they remain localized in the region around the clot. This irritative process serves to establish encysting of the clot. 5. If very much blood have been effused, the serosity exuded during coagulation has not time to be all absorbed before the appearance of phenomena of reaction. The serosity then becomes altered, and its presence gives rise to bad symptoms. 6. The symptoms and prognosis of traumatic hæmothorax vary in these two classes of cases. In the former, the prognosis is favourable; in the latter, it is grave. The rules of treatment are thus formulated. 1. In cases of stabbing, immediately after the injury to close the wound. This occlusion to be made either with gutta-percha tissue or with wadding and collodion. 2. If the symptoms of dyspnœa and the fever diminish gradually, to leave the patient at perfect rest and to avoid any interference. 3. If inflammatory symptoms be suspected between the eighth and twelfth days, to treat these by blistering and local bleeding. 4. But if the oppression of breathing and the fever, instead of diminishing rapidly, remain stationary or increase in intensity, it is necessary to act at once, and to evacuate the effused fluid. The surgeon should at first make a capillary puncture; if the effusion consist simply of dark coloured serosity, this method will be found the best; it will suffice to empty the pleura, and is not so grave a procedure as that requiring a counter-opening. If, however, the effused fluid have already undergone a change, and have become purulent and fetid, it will be necessary to evacuate the effusion, as in a case of empyema, in order that by frequent injections such phenomena of putridity as are presented may be effectually dealt with.—*London Med. Record*, Oct. 15, 1880.

—

Remarkable Heart-murmur Heard at a Distance from Chest-wall.

Numerous cases of heart-disease are on record in which a murmur could be heard at some distance from the chest. The following instance, reported by Dr. WILLIAM OSLER, Physician to the General Hospital, Montreal (*Med. Times and Gaz.*, Oct. 9, 1880), is remarkable from the absence of any evidence of serious cardiac disease, and from the exceedingly variable nature of the murmur:—

J. W., aged twelve, a well-nourished young girl, was sent to Dr. Osler in May last by Dr. Buller, who had noticed a remarkable whistling sound while examining her eyes. The mother states that she has been a healthy child, though never very robust. Had inflammation of the lungs at eighteen months, measles at the age of three, and scarlet fever three years ago. When stripped, and sitting quietly on a chair, the following facts are noted: Posture slightly stooping; shoulders rounded, chest long, ribs oblique, sternum short, and xiphoid cartilage tilted forward. Expansion of chest equal on both sides. Apex-beat is seen in fifth interspace in normal situation. No protrusion over heart, or irregularity in the attachment of the ribs to sternum over cardiac region. Heart's impulse is forcible, but not heaving. Area of dulness not increased.

Auscultation.—As she sits upright in the chair the heart-sounds at apex and base loud and clear; no murmur. When she stands, a loud systolic murmur is heard at apex, high-pitched, somewhat musical, of maximum intensity in fifth interspace; it varies a good deal, being loud for three or four beats, and then faint for one or two succeeding ones, due to influence of respiration. On removal of ear from the chest-wall the murmur can be distinctly heard at a distance of several inches. It disappeared quite suddenly, and could not be detected on most careful examination. She was then asked to run about the room and up

and down stairs. On sitting down after this the heart's action was very forcible, but the sounds were perfectly clear. The child then suggested that she heard it most frequently when in the stooping posture; and on causing her to lean forward and relax the chest the murmur was at once heard, and with greatly increased intensity. It was distinctly audible at a distance of three feet two inches by measurement, and could be heard at any point on the chest and on top of the head. Pulse 96.

On May 28 she was shown at the Medico-Chirurgical Society of Montreal, and most of the members heard the murmur. A day or two before the meeting Dr. Osler called at her mother's house and satisfied himself of its presence, though it was very variable.

On July 13 he saw her again at her home, and failed, after prolonged examination, to hear the murmur. She stated that she had not heard it herself for some time. There was nothing special to note about her condition, which seemed unchanged; she enjoyed good health. The stooping posture had no influence in developing the murmur as at the first examination.

July 21. Came this morning for examination. While she remained sitting, heart-sounds clear, impulse tolerably strong. When she stood up, the murmur at once became evident, presenting the same characters as before described, but not so loud, nor could it be heard at such a distance from the chest-wall. It was not much influenced by posture, though somewhat intensified when the shoulders were brought well forward. It persisted for a short time after she sat down, and then disappeared. Running up and down stairs did not cause its return, but a minute or two after it again became audible. For two or three beats it was loud, and then diminished in intensity, but there was no constancy in these variations. The rhythm is distinctly systolic; the first sound of the heart is not effaced by it, though not so sharp as in its absence. During an examination extending over twenty minutes the murmur was present four or five times, and for a brief interval only—less than a minute each time.

August 31. Saw her again, and failed to hear a murmur in any posture, after a prolonged examination. Heart-sounds clear and sharp. Has been very well. Says she has not heard the murmur for some time; does not know that there is any special time when she hears it most distinctly. Is not very short of breath after running up stairs. Heart's impulse certainly appears stronger than normal, though not heaving. Pulse 100, of good volume.

Remarks.—The points of interest in this case are, as stated above, the absence of signs of grave heart-disease, and the extreme variability of the murmur. In aortic-valve disease, particularly stenosis, it is not very uncommon to have such a loud murmur that it may be heard at a distance of several inches from the chest-wall. Dr. Osler has had two such cases under his care lately; in both the murmur was audible at about three inches from the sternum; in one of them, sent by Dr. James T. Munro, the murmur was stated to have been heard several feet off. The subject is dealt with very fully by Professor Ebstein,[1] who has collected records of numerous cases. In his exhaustive review of the literature of the subject he has only found three or four instances of such murmurs unaccompanied with serious disease of the heart or large vessels. Two of the cases are reported by Stokes:[2] one a weak, nervous woman, the other a chlorotic girl; in both it disappeared. The third case occurred in the person of Professor Baum, a colleague of Dr. Ebstein's, who, from 1854 to 1857, had a murmur synchronous

[1] Deutsches Archiv f. Klin. Medicin, Bd. xxii., 1878.

[2] Diseases of the Heart, page 154.

with the heart's impulse, which was so loud that it could be heard at a distance from the chest. It was most marked at night time. The symptom disappeared completely, and does not seem to have interfered in any way with Dr. Baum's health, as at the date of Dr. Ebstein's writing he had reached the age of seventy-eight. Dr. Baum had met with a somewhat similar case in a clergyman, in whom also it finally disappeared. The case here reported would appear to belong to this group, as there is no indication of serious disease of either the heart or vessels. The apex-beat is in the normal situation, and though the impulse is increased in force, the evidences of an hypertrophy dependent upon organic disease are very slight. If the murmur originated in a stenosed aortic orifice—the lesion in most of the cases—there would be symptoms of this condition, increased area of cardiac dulness, etc., and, moreover, it would be, in all likelihood, persistent; not, as this one, extremely variable. The remarkable way in which the murmur appears and disappears is the most singular and puzzling feature. Dr. Osler thought after the first examination that it was only developed in the relaxed condition of the chest, with the shoulders well forward and the head bent, in which position there might be slight pressure exercised by the sternum or costal cartilages on the aorta or the pulmonary artery. Subsequent examinations, however, proved this to be erroneous. Evidently the murmur is diminishing in intensity, and is not heard so constantly. Dr. Buller states that on the first occasion on which he saw her it was audible half-way across the room, at a distance of six or eight feet. She was at the time very nervous and much excited. Dr. Osler is not prepared to suggest an explanation of the cause of the murmur in this instance. It is worthy of note that in three of the five cases of this sort here mentioned the patients were women—two of them weak and anæmic; and the third (the girl under my care) delicately built and nervous, though not anæmic.

The Pathogeny of Pericarditis.

Professor ZENKER, of Erlangen, at the fifty-second annual meeting of Physicians and Naturalists at Baden-Baden, called the attention of practical physicians to a mode of origin of pericarditis, which, although no doubt it had not hitherto escaped attention, was, in his opinion, not yet recognized sufficiently often, in relation to what he believed to be its relatively great frequency. This is the causation of pericarditis, by processes of ulceration in the posterior mediastinum, whether these processes only reach the pericardium, or lead to actual perforation of it. These ulcerations are usually related to perforations of the œsophagus or bronchi, being caused either by such perforations, or the perforations in the œsophagus and bronchi, or in both, being secondary. In both cases, the communication thus set up with the external air readily gives rise to suppuration and to a further spread of the ulceration, in which the pericardium is easily involved. The pericarditis thus excited may be either fibrinous or suppurative, and also, where there is simultaneous perforation of the pericardium and of the œsophagus or bronchi combined with pneumo-pericarditis. *Post-mortem* observations have shown to Dr. Zenker the relative frequency of these processes, as well as the frequent recovery from the pericarditis thus arising. The insidious commencement and the almost entire absence of symptoms in the course of mediastinal ulcerations, as well as their obscure seat, explain the little observation which this subject has yet obtained either at the bedside or in the *post-mortem* room. Among the causes of mediastinal ulceration, perforation of diverticula of the œsophagus appears to play a prominent part. The possibility of making a more sure diagnosis of these processes, so as perhaps to act more effectively on

them by therapeutic means, does not appear to be excluded, looking to the progress in physical diagnosis which characterizes modern medicine. In any case, however, it will be possible to clear up by observation of these facts in pathological anatomy, many cases of pericarditis of which the pathogeny has hitherto remained concealed. Professor Wyss, of Zürich, laid stress on the practical importance of this communication, and remarked in a general way on the relations of the posterior mediastinum to the affections of the pericardium. He related a case of diphtheria with secondary suppurative inflammation of the mediastinum and an extension of the inflammation to the pericardium. In a second case a workman fell ill with dysphagia, which was followed after some time by pericarditis. He died with symptoms of tuberculous peritonitis. At the necropsy, there were found tuberculous peritonitis and pericarditis. The bronchial glands had undergone tubercular degeneration, and were adherent to the pericardium, which was perforated. He remarks on this, that not only fibrinous, suppurative, and septic pericarditis, but also the tubercular form of it, may take its origin from the mediastinum, especially from the bronchial glands.—*London Med. Record*, Oct. 15, 1880.

Abdominal Faradization in Ascites.

POPOFF (*Vratsch*, 1880, No. 22) describes a case of ascites, with enlargement of the spleen, treated by faradization of the abdominal muscles and of the spleen. He gives a table showing the effects of the treatment on the quantity of urine excreted. This rose on the first day from 1200 to 3500 cubic centimetres, and was always much greater on the days when the patient was faradized. The circumference of the abdomen steadily diminished from 95 to 80 centimetres, whilst the size of the spleen fell from 10 × 8 to 7 × 5 centimetres.—*London Med. Record*, Oct. 15, 1880.

Surgery.

Nerve-stretching.

At the last meeting of the Society of German Surgeons in Berlin (*Med.-Chir. Centralblatt*, No. 31), Dr. CREDÉ, of Dresden, showed a patient on whom he had performed stretching and division of the third branch of the trigeminal nerve by a modification of Lücke's method. He made an incision down to the posterior surface of the upper jaw. The lower jaw had to be dislocated; he then penetrated beneath the periosteum as far as the foramen ovale, seized the nerve with a blunt-hook, and isolated the middle meningeal artery. He then stretched the nerve, and cut it through at the base of the skull. There was no febrile reaction; and the neuralgia was removed.

A long discussion followed on the usefulness of nerve-stretching. Opinions were divided. Esmarch had carried out nerve-stretching seven times with good results; once he had stretched the brachial plexus in tabes with success. Trendelenberg was not so fortunate; he had employed nerve-stretching in six cases, with only one example of success. He was undecided whether nerve-stretching was indicated in tetanus or in tabes. Sonnenburg did not observe any success in tetanus. Vogt laid emphasis on the point that the nerves must be very strongly stretched, and that only the large nerves could be treated. Langenbeck reported that in the cases which he had published of nerve-stretching in tabes, relapse had

occurred; and so also in the case of intercostal neuralgia which Nussbaum, on his part, had reported.

In the *Voyenno Meditsinsky*, quoted in *New York Medical Record*, August, 1880, it is stated that Dr. A. GEN collected 73 cases of nerve-stretching used as a therapeutic measure. In traumatic neuralgia it was employed 6 times—cured 4, improved 1 (recovered entirely after neurotomy), no improvement, 1; in neuralgia from other causes, in 14 cases—cured 10, improved 3, 1 died from the hemorrhage; in clonic spasms and contractions, 6 times—cured 4, no improvement 2 (one cured by neurotomy); in peripheral epilepsy, once—cure; in tetanus, 16 times—cured 7, symptoms improved, but disease terminated fatally in 6, symptoms did not improve and patients died, 3; in anæsthetic leprosy, 30 times, in all cases with marked benefit.

As the therapeutic action of nerve-stretching is not well understood, he performed some experiments in the laboratory of Prof. Tarchanoff with a view to determine it. Some of his conclusions are as follows: Not only mild stretching, but also the use of force equal to half what is necessary to rupture the nerve, may produce an increase of its irritability and conduction. Mild stretching has no effect upon the reflex irritability, but if the force used be great, it is diminished; this effect is also observed on the opposite side, indicating the central seat of the change in its effects. Hence the operation is not limited to the peripheral parts only of the nerve, as Vogt was inclined to think. Under the microscope, he found the traces of hyperæmia and capillary hemorrhages; the axis-cylinders and myeline might be severed, but Schwann's sheath was intact. He found also peculiar constrictions in the medullary fibres. He considers that the diminution of the reflex activity is the main feature, and in the cases operated on was the condition called for.

Dr. POOLEY (*New York Medical Record*, 1880, p. 173), collects 37 cases, and adds two of his own. In the operations, as recorded in his table, the following nerves were stretched: the sciatica, sixteen times; the crural and the median, each five times; brachial plexus and ulnar, each four times; the tibial, three times; the musculo-spiral, twice; the supra-orbital, spinal accessory, facial, inferior dental, and peroneal, each once; making a total of forty-four nerves stretched in the thirty-five cases.

In all the cases of neuralgia (six of sciatica and seven of other forms) except one, the operation has been beneficial, and in most of them the cure has been complete. In the exceptional case, it seems very probable that if the nerve which was subsequently excised with success had been stretched in the first instance, instead of the sciatic, the result would have been favourable. The special form of neuralgia known as sciatica has yielded excellent results from nerve-stretching, which may now be regarded as a thoroughly recognized procedure in obstinate cases. Professional opinion seems to be steadily advancing in favour of the operation in other forms of neuralgia. Especially in the traumatic variety is it likely to prove useful, as here there are more generally found adhesions of the nerve to surrounding tissues which stretching may break up. In such cases it has been found not only to cure the pain, but also the wasting shiny skin, and other trophic disturbances associated therewith.

The success of nerve-stretching is little less marked in local convulsive affections than in pure neuralgia. It is in this class of cases that the most extensive operations have been resorted to—stretching of several nerves, and on both sides of the body—but no ill consequences have resulted to diminish the value of the result.

In the twelve cases of traumatic tetanus for which the operation was done, seven of the patients died, four recovered, and in one the result is not stated.

There can be no doubt that, as the matter at present stands, a physician would be culpable who trusted to nerve-stretching alone in this disease, and it may be doubted whether the cases where it has been done as an adjuvant to other treatment show any better average results than from the treatment by chloral-hydrate and (?) Calabar bean.—*London Med. Record*, Oct. 15, 1880.

—

On the Detection of the Presence and Location of Steel and Iron Foreign Bodies in the Eye by the Indication of a Magnetic Needle.

Dr. THOMAS R. POOLEY, of New York, in an interesting paper on this subject (*Archives of Ophthalmology*, Sept. 1880) based upon a series of experiments, deduces the following conclusions.

1st. The presence of a steel or iron foreign body in the eye, when of considerable size and situated near the surface, may be determined by testing for it with a suspended magnet.

2d. The presence and position of such a foreign body may most surely be made out by rendering it a magnet by induction, and then testing for it by a minute suspended magnet.

3d. The probable depth of the inclosed foreign body may be inferred by the intensity of the action of the needle near the surface.

4th. Any change from the primary position of the foreign body may be ascertained by carefully noting the changes indicated by the deflection of the needle.

—

Scarlet Fever as a Cause of Ear-Disease.

The above subject is treated by Dr. BURCKHARDT-MERIAN, Professor at Basle, in an able lecture[1] in Volkmann's *Sammlung Klin. Vorträge*, No. 182. It is one which deserves the attention of our profession, owing to the frequency with which scarlet fever attacks the auditory apparatus, and the disastrous results which too often follow neglect of proper treatment in the early days of the affection of the ear. Of 1950 aural cases of his own, Dr. Merian found that 85, or 4.35 per cent., were due to scarlet fever. Yearsley found 4.77 per cent. of his cases dependent on the same cause. In 18 of Merian's 85 cases—that is, in 21.17 per cent.—the hearing was totally lost in one or both ears, and three of these patients were deaf-mutes. The statistics of deaf-and-dumb institutions speak strongly as to the causation of deaf-mutism by scarlet fever; Dr. Merian tabulates 4309 cases of acquired deaf-mutism, of which 445, or 10.32 per cent., followed that disease. These facts will suffice to impress the importance of this subject on our readers.

There has been a good deal of discussion as to the way in which the middle ear first becomes involved during scarlet fever. Dr. Merian believes that the inflammation of the fauces extends upwards through the Eustachian tube or tubes, and that the cases where perforation of the tympanum afterwards occurs are those in which this inflammatory process is of a *diphtheritic* nature, diphtheritic patches being present at the same time, though often overlooked, on the soft palate and in the pharynx. There are no doubt a number of mild affections of the middle ear, which have nothing to do with diphtheria, but depend on the extension of a chronic congestion of the pharynx to the mucous membrane of the tympanic cavity; but these often rapidly subside without permanent injury to the ear. With the diphtheritic form it is far otherwise. Dr. Merian thus describes its symptoms. In the majority of the cases they first appear in the stage of desquamation; there is often a rigor and always a fever, which remits in the morning, and may rise to

[1] Ueber den Scharlach in seinen Beziehungen zum Gehörorgan.

39.5° Cent. (102° Fahr.), seldom higher, at night. Severe earache is complained of, which may be replaced in a few hours, especially if spontaneous rupture of the tympanum takes place, by pains of a true neuralgic character involving the second and third branches of the fifth nerve. More or less complete deafness is the rule, and may come on very rapidly. The anterior and posterior auricular lymphatic glands, as well as the submaxillary and cervical glands, almost always enlarge, and their enlargement may precede all other symptoms of the middle ear. Sometimes the mastoid process is painful on pressure, and especially on percussion, without any consecutive inflammation happening. All these symptoms, with perhaps the single exception of the glandular swelling, may also occur in an acute inflammation of the middle ear not due to scarlet fever; but there is *one* symptom peculiar to the otitis media of scarlet fever, or at any rate only met with in connection with it and with diphtheria, namely, the rapidity with which the tympanic membrane becomes destroyed in whole or in part. In ordinary inflammation this generally takes years; in the otitis of scarlet fever and diphtheria, only a few weeks. How common the destruction of the membrane after scarlet fever is, the following statement will show. Dr. Merian found in his 85 cases that 13 had had one ear and 72 both ears attacked. The total number of ears involved in these 85 cases was, therefore, $72 \times 2 + 13 = 157$, and of these 54, or 34.34 per cent., had completely lost the membrana tympani. When we reflect further on the other consequences of the otitis media—the chronic profuse suppuration after perforation of the membrane, the loss of the auditory ossicles, the formation of polypi, and in the worst cases erosion of the carotid artery and of the transverse sinus at an early period, or cerebral abscess at a late period—the importance of early and appropriate treatment is sufficiently evident.

This treatment is not only to be curative, but prophylactic. Dr. Merian holds that the best preventive of aural mischief in scarlet fever is the arrest of the primary diphtheritic process in the pharynx. He therefore cauterizes all patches that can be discovered, at first twice, and afterwards once a day, with a 10 per cent. alcoholic solution of salicylic acid. A piece of cotton-wool of the required size is wound round the end of a small knitting-needle on which a double screw is cut, and the wool, soaked in the liquid, is gently pressed on the part. Some pain is caused, but it does not last long. Nausea is best combated by ice, and the taste of the spirit can be concealed by adding 1 or 2 per cent. of oil of wintergreen to it. For the back of the soft palate and for the pharynx curved instruments are, of course, required.

The second preventive measure is the use of the nasal douche once a day where the patient is intelligent enough to bear it. Following Tröltsch (*Archiv für Ohrenheilk.*, Bd. ix. S. 191), Dr. Merian provides a printed form of directions for its proper manipulation. The apparatus consists of an Esmarch's irrigator, with a tube two feet long, furnished with a glass nose-piece. A litre of warm water, in which seven grammes and half of common salt have been dissolved, is the liquid employed at first. Without the salt the water irritates the nares. Later on, one or two tablespoonfuls of salicylated spirit are added to each litre. It is very important that the douche be slowly administered, the patient breathing quietly with open mouth, and not speaking or swallowing. The irrigator must not be raised more than one foot above the level of the head, else water may easily enter the Eustachian tube and penetrate the ear, giving rise not only to pain, but possibly to tedious inflammation. Our space will not allow us to reproduce Dr. Merian's instructions more fully. Besides the douche he recommends gargling every two or three hours with a dessertspoonful of salicylated spirit in a small glass of water, and the application of an ice bag to the front of the neck from one mastoid pro-

cess to the other. Pieces of ice are also allowed to dissolve in the mouth, but the patient is told to spit out the water formed from it. Very small children are excited to sneeze, and so temporarily clear their nares, by a snuff of pure salicylic acid, which for infants may be diluted with equal parts of starch-powder. Before leaving the subject of prophylaxis, Dr. Merian mentions that it has seemed to him that consecutive ear-affections have been most often met with in cases of scarlet fever treated by cold baths or the cold "pack," both of which tend to cause congestion of the head.

In treating the acute stage of the otitis itself he uses ice externally, protecting the very sensitive lobe of the ear from the cold by flannel or a piece of wadding. The pain is relieved by iodine paint, or by iodoform ointment (iodoform, ol. fœniculi, āā 1.0 gramme, vaseline 8.0) covered with gutta-percha tissue, and over it the ice-bag. Very severe pain yields to equal parts tinct. opii and water, ten to twenty drops being poured into the meatus. The intermittent pains occurring towards evening or by night, and which are very depressing to the patient, require quinine (0.20 to 0.50 gramme) internally.

As soon as the acute stage is over, air should be blown into the tympanic cavity with a Politzer's bag, to restore the equilibrium of the internal air with the external atmosphere, and allow the membrane, which has yielded to external pressure, to recover its position. If, however, in spite of these measures, the fever continues, the mastoid process is tender, and dull pain is felt over the whole head, paracentesis of the tympanum is indicated. The opening made should not be too small, and there is generally rapid relief after the operation. The escape of secretion from the middle ear should be aided by Politzer's bag. Syringing should be avoided the first day, and wadding, frequently changed, alone used to soak up the discharge. The patient is ordered to lie on the side of the affected ear; and if, as often happens, great improvement follows the puncture, iodine and ice alone suffice for the cure. If, however, the discharge is copious and with difficulty checked, the ear is syringed with a 5 per cent. solution of sodic sulphate, which Dr. Merian has long preferred to all others for this purpose (see *Correspondenz-Blatt für schweizer Aerzte*, 1874, S. 566). The wadding he uses is boracic. The very destructive diphtheritic forms of otitis media require the membranes, which often fill the whole osseous meatus and obscure the tympanum, to be scraped away energetically with a curette or removed by a "Wilde's snare," and the parts to be daubed with salicylated spirit, or dusted with pure salicylic acid; the ear must also be syringed several times daily with diluted salicylated spirit (one to two dessertspoonfuls to 100.0 grammes water). These proceedings are rather painful, but generally wonderfully efficacious. Profuse suppuration in these latter cases without fever is best treated by thorough syringing twice a day either with diluted salicylated spirit, carbolic acid (acid. carbol., sp. vini, āā, one dessertspoonful to 100.0 grammes water), or boracic acid (one to two dessertspoonfuls to water Oss.) By the adoption of these measures at the outset, Dr. Merian is convinced that the number of cases of chronic ear-disease after scarlet fever will be much reduced, as well as the danger to hearing and to life which is its too frequent consequence.—*Med. Times and Gaz.*, Oct. 30, 1880.

—

Nephro-Lithotomy.

Mr. Henry Morris, at a late meeting of the Clinical Society of London (*British Med. Journal*, Oct. 30, 1880) read a paper on this subject, with notes of a case in which the operation was successful. By the term "nephro-lithotomy" was meant the removal through a lumbar incision of a renal calculus from a kidney in which the pelvis was not dilated, and which, but for the presence of

the stone, was presumably healthy. It was to be distinguished from the numerous cases in which the kidney was cut for the evacuation of fluid accumulated within it, whether as the result of a renal calculus, of tuberculous disease, or some other cause, and to which, from very ancient times, the name "nephrotomy" had been applied; as well as from those cases, also numerous, in which a stone had been removed after it had been detected through a sinus in the loin. The opinion of writers upon the subject had been universally adverse to the attempt to remove a stone from the kidney, unless it could be reached through a distended pelvis—the chief reason urged being danger of fatal hemorrhage if the existing substance of the organ were cut or torn. The case described in the paper conclusively proved the feasibility of the operation; and, in answer to the question —Was nephro-lithotomy feasible, and, if feasible, was it safe? the author stated "that it was entirely due to his friend and colleague, Dr. Coupland, who advised the patient to undergo the operation, that an affirmative answer could now, for the first time in the history of surgery, be given with certainty to the question." The position of the question before this case occurred was reviewed; Marchetti's operation on the English Consul Hobson was referred to, and six cases in which the operation was planned, but in which it proved abortive, were mentioned. These six cases were considered encouraging, because all the patients recovered from the operation of exposing the kidney, and, curiously enough, obtained, at least for a time, relief from their symptoms.

Case.—Maria M., aged 19, a servant-girl, of short stout stature, and with a remarkably rough scaly skin, had for eight years been subject at times to pain in her right side, accompanied occasionally with a feeling of sickness, and even actual vomiting. In September, 1878, these symptoms became more pronounced; her urine became dark-coloured, and the pains so severe that she had to give up her situation and go under medical treatment. In April, 1879, she was admitted, under Dr. Thompson, into the Middlesex Hospital, and, after treatment and rest, so far improved that she went again into service. A life of activity, however, brought back the old symptoms, and she was readmitted (this time under Dr. Greenhow) into the hospital. In less than a month she was again able to go out, but only to return a third time, with urine as dark as porter, and with the pains in the right loin and groin as severe as ever. When she was admitted, under Dr. Coupland, on December 29th, 1879, her urine was acid, and contained no other abnormal constituents than blood; there was some tenderness, but no swelling in the right loin. Again the urine cleared up, but the nephralgia was not relieved; consequently, on February 11th, chloroform was administered, and the right kidney exposed through an oblique lumbar incision. The right index-finger was then passed over the posterior surface of the kidney, and at once detected something faintly projecting over the renal substance near the hilus. The renal substance was incised at this spot with a probe-ended bistoury, and a mulberry calculus, of triangular shape, and weighing thirty-one grains, was extracted by means of a scooping movement of the finger-tip. There was no hemorrhage at any stage of the operation. The upper end of the ureter was not dilated in the least, and, as the stone could not be felt there, it was consequently not interfered with. No attempt was made to examine the front surface of the kidney. The wound was brought together with three sutures, and a drainage-tube was introduced between two of them. The patient made a good recovery; urine ceased to flow through the wound on May 4th, and at the present time there was nothing whatever the matter with the patient, excepting that a sinus of one and three-quarter inches still remained in the loin, and discharged about a drachm of pus daily.

This case showed that a calculus could be extracted from an *undilated kidney*

by surgical operation, without more risk than was amply warranted by the sufferings and general disability which the operation was designed to remove. But before the success of one case was allowed to influence treatment in others, four questions required consideration. 1. Could the diagnosis as to the disease, and the organ affected, be made with certainty? 2. What were the prospects of being able to complete the operation when a stone was found? 3. What were the dangers of the operation? 4. What was the best result which could be hoped for from the operation if successful? Mr. Morris, in answering each of these questions, gave arguments in favour of nephro-lithotomy; and finally expressed his agreement with Mr. Charles Bernard, the author of an account of Marchetti's operation, described in the *Philosophical Transactions* of 1696, that many of the writers upon the subject of wounds of the kidney "ought not to have so magisterially exploded the operation;" and hoped the operation would once again receive the consideration of the profession.

Mr. LUCAS said he had been looking for such a case, but had not found one. The experience gained, however, when the whole kidney was removed, was likewise available in such instances. Cutting down upon the kidney was, comparatively speaking, a trifling operation, though the risk of leaving a permanent sinus was considerable.

Mr. GOLDING-BIRD had operated on one case, but had failed to find a stone. The boy suffered from intense pain in the bladder and about the kidney. The organ was cut down upon, and nothing found, but the pain was relieved. The pain returned, and the bladder opened, but nothing found. The end of the case was unfortunately unknown.

Mr. BARKER said that a case had been reported, where a canula had been thrust down through a small opening and struck the stone; this canula had been allowed to remain in, and the wound afterwards dilated by tents until a lithotrite could be introduced, and the stone crushed and removed. He had recently had a case where a large branched calculus filled the cavity of the kidney. He was able to remove a part, but not the whole. He then endeavoured to remove the whole kidney. The patient died of shock.

Mr. BRYANT said he would support Mr. Morris's view as to the operation in his case, though it was a dangerous one. Granting the presence of a stone, and a persistence of symptoms refusing all amelioration, the surgeon was justified in operating. Still, there were many cases where the stone would settle down in the kidney, and the patient survive many years, dying finally of something else. As regarded diagnosis, it was quite true that the stone might be struck by a needle thrust down upon it, but it was a question how far this plan should be tried. He suspected that the evil would exceed the good done.

—

Spasmodic Stricture.

Prof. ZEISSL publishes in the *Allg. Wien. Med. Zeit.* (Nos. 23 and 24) the portion of his forthcoming report on his division of the Vienna General Hospital, which relates to spasmodic stricture of the urethra. After adverting to the difference of opinion which has prevailed upon the reality of its existence from the time of Hunter, who first described it, and finding that this is still denied by some observers, he thinks it incumbent upon him to state what has so frequently come under his own notice.

Every one, he observes, knows how sensitive the bladder and urethra are to external influences, whether these are of a thermic or a mechanical kind, and the action of psychical influences on their functions is no less remarkable. Many men, even with a well-filled bladder, are not able to empty it while talking or

laughing; and the case of a young man is cited, who during a railway journey was unable to pass water, although the train stopped at several stations for five or ten minutes, because he was always in fear that it would go off without him. When this fear had ceased to operate at the end of the journey, he at once emptied his highly distended bladder. As to the etiology of spasmodic stricture, even a slight chemical change in the urine may induce it. A catarrhal condition of the urethra, excessive coitus, hard riding, taking imperfectly fermented drinks, and especially organic stricture of the urethra, may also induce the spasm and give rise to retention of urine. This is not infrequently met with during gonorrhœa. Patients suffering from this often drink large quantities of liquids containing free carbonic acid, and become the subjects either of catarrh of the neck of the bladder with very frequent passage of urine, or of retention of urine. When called to such cases, we find them with the most anxious expression of countenance, the brow covered with cold sweat, and the bladder distended so as to reach the umbilicus, no urine being discharged in spite of the strongest efforts. A catheter of the largest size corresponding to the diameter of the urethra can, with a little patience on the part of the surgeon, be passed in with ease. It has frequently happened to Prof. Zeissl to find that the passage of a large bougie or sound for the treatment of chronic gonorrhœa has been impossible in individuals on the first occasion of this treatment being adopted; but after the instrument has remained at the obstructing part (usually the membranous portion) for some minutes, and often for a quarter of an hour, it slips in of itself. After the patient has become aware of the painlessness of the procedure, and ceases to have any fear, the instrument, on the very next occasion, can usually be passed with ease. These facts show that the action of the muscular structure of the urethra may prevent the entrance of a bougie or the discharge of urine. These urethral spasms are of frequent occurrence, and are found in persons who are suffering from organic stricture. They are not confined to any definite part of the urethra, but may affect any part of it. These spasmodic strictures are often a serious hindrance to the treatment of organic stricture, the spasm being induced by the introduction of an instrument. Not only is the introduction of an instrument opposed by the spasmodic action, which, however, may be overcome with patience, but its withdrawal is delayed by the same cause, often for a very long time, which is a great inconvenience in private practice.

After relating some cases in exemplification, Prof. Zeissl observes that a series of similar facts have convinced him that the muscular structure of the urethra may exhibit spasmodic action, and that the consequences of this diseased contraction may, (1) in rare cases, induce retention of the urine, the spasm then attacking the muscular structure surrounding the membranous portion—the musculus transversus perinei profundus; (2) it very frequently prevents the introduction of an instrument for some minutes; (3) it may become so severe in any part of the urethra that for a time it may render the withdrawal of an instrument impossible; (4) it may give rise to prostatic discharges and frequent pollutions. In reference to this last point, he observes that sometimes patients present themselves complaining of very frequent pollutions. They perceive a kind of fulness of the penis, as if it were filled with fluid from before backwards, and this is accompanied by a sensation of contraction in the glans. When these sensations cease, a small quantity of grayish-white fluid, containing filaments, flows from the urethra. There is no obstruction to the flow of urine, but a few seconds after this has ceased, some additional drops are discharged. This last symptom would seem to indicate hypertrophy of the prostate, but as most of these patients are about twenty years old only, it cannot arise from that; and, in fact, the passage of a sound and examination of the rectum prove that no such hypertrophy

exists. The endoscope exhibits no abnormality of the urethral mucous membrane, nor is there hyperæmia or tumefaction of the vera montanum. The symptoms are, however, easily explained if we attend to what takes place when a sound is passed. It will be found that a well-oiled instrument can only be carried forward irregularly and by starts, being sometimes arrested at certain points, and if held with a light hand it may be turned round on its axis. There is, in fact, throughout the whole course of the urethra, but especially at the prostatic portion and the anterior part of the canal, a spasmodic condition. We know, from the researches of Brücke and Svetlin, that the greater part of the prostate consists of muscular substance surrounding the tubular glands. This muscular substance contracts spasmodically, and forces the secretions of the gland into the urethra, filling the prostatic and membranous portions first; and as soon as the prostatic secretion arrives in the urethra, the muscular structure of this is spasmodically affected, especially at the anterior portion, so as to impede its exit and induce the sensation as if the urethra were filled with fluid. After some minutes the spasm ceases, and the retained prostatic secretion flows from the urethra. On examination of the fluid thus expelled, no spermatozoa are found. The discharge of some drops of urine a few minutes after the flow has ceased is explained as follows: The greater part of this fluid is discharged on the contraction of the bladder, but as it flows through the urethra it induces muscular contraction, and when this becomes stronger than that of the detrusor the discharge of urine is arrested for some minutes until the spasmodic action has subsided. With respect to the occurrence of the pollutions, we know that under sexual excitement the secretion of the prostate is quickly discharged; and when its muscular substance contracts spasmodically in sleep and discharges its secretion, the patient becomes the subject of lascivious dreams, and seminal emissions ensue. This form of spasmodic stricture is especially observed in spinal disease or as a forerunner of this; but it may also occur in individuals whose central nervous system is in a completely healthy condition.

With regard to the treatment of this disagreeable affection, which also in its last-named form may prove injurious to the entire system, we should first forbid all drinks which exert an irritating effect upon the bladder, especially champagne, cider, new wine, and beer. The most important point is the daily introduction of a moderately large instrument into the urethra, and leaving it there for only a few minutes. It is also very serviceable, when the spasmodic action of the urethra affects a person who is the subject of an organic stricture, to order for him, an hour before the introduction of the instrument, either a morphia or belladonna suppository or a small dose of morphia. At the end of an hour an amount of narcotism is often induced, under which a urethra that before was impassable admits with ease a large instrument. The belladonna suppository is preferable to the morphia, because while, like it, it counteracts the spasmodic action, it does not induce constipation. The patient should also keep as quiet as possible in a room of equable temperature, make warm applications to the perineum, and use a warm sitz-bath twice a day.

"The exact recognition of spasmodic stricture is, in my opinion, of the greatest importance, because every one who is aware of its existence, when he meets with an obstruction while examining a urethra, will not endeavour to overcome this with force, but will allow the instrument to remain quietly for some seconds at the obstructing point, which he will soon be able to glide over with ease if the obstruction is induced by spasm. These spasmodic strictures explain the frequency with which false passages are made, by imprudent exploration, in urethras which exhibit no organic strictures."—*Med. Times and Gazette*, Oct. 23, 1880.

Osseous Ankylosis of the Knee operated on by Barton's Method.

Mr. M. H. KILGARRIFF relates the following case in the *Dublin Journal of the Medical Sciences* for March, 1880. M. H., aged 30, the subject of faulty bony ankylosis of the knee, was admitted into Jervis Street Hospital on the 4th September, 1877. On examination, the leg was found to be bent at a right angle, the knee immovable, the anterior and lateral aspects being rough and irregular, and covered with a thin slate-coloured cicatrix. On the 16th September, assisted by his colleagues, Mr. Kilgarriff operated. Ether having been administered, he cut on the lower portion of the thigh a triangular flap, with the base on the outside, exposing the femur. He then passed carefully under the bone a curved metallic spatula, and with a saw removed a wedge-shaped piece of bone which had its base in front, and measured vertically three-quarters of an inch. He then straightened the limb without difficulty, and placed it in a splint, the outside piece of which reached the axilla while the inner part fell short of the groin; the lower portion was a box, and joined the thigh part at a very obtuse angle. The dressing consisted of lint steeped in carbolized oil, and a solution of permanganate of potash was used to wash the site of operation. The wound suppurated for a few weeks, then closed in, and the divided surfaces of the bone were early united by a firm osseous band. In somewhat less than three months the patient was able to lean on the leg, and, aided by crutches, could without difficulty walk about the ward. The operation differed from Barton's in two particulars, which Mr. Kilgarriff regards as an advantage, viz., cutting through the bone, which left no spicula to pierce the fascia behind, and having the base of flap at the outside averted the possibility of bagging of matter, and made the wound more accessible for dressing. In Barton's method the bone posteriorly was uncut, and the flap was on the inside. In the above case there was no shortening, and the patient could walk well and discharge her duties as a servant.—*London Med. Record*, Oct. 15, 1880.

Case of Resection of the Patella.

In a recent contribution from Dr. E. ALBERT, of Innsbruck, to the literature of practical surgery (*Beiträge zur Operativen Chirurgie*, 1880), a report is given which, though referring to an operation performed nearly three years ago, may now be regarded as one of particular interest in its relation to the views that have since been published by Volkmann, as to the pathogeny of articular white swelling. Volkmann has reported (*Sammlung Klinischer Vorträge*) cases of coxitis, due to osteomyelitis of the head and neck of the femur, in which, after having chipped away the outer wall of the great trochanter, he removed an inflammatory deposit from the interior of the bone. Osteomyelitic deposits were also removed in like manner from the articular extremities of other bones, and the neighbouring joint, in each case, was laid open and drained. In his comments on these cases, Volkmann endeavours to show that the destructive articular disease known as white swelling has its primary origin, not in any pathological change in the synovial membrane, but in deposit, usually tubercular, in the medullary portion of an adjacent bone. It is suggested that the destruction or removal of such deposit should be attempted when practicable, notwithstanding the unfavourable experience of surgeons as to caries of bone, and the frequent occurrence of death soon after recovery from resection of a diseased joint.

The case recorded by Albert is one of well-marked fungoid disease of the knee, which evidently had its origin in caries of the patella. According to Volkmann, the internal condyle of the femur is most frequently the seat of tubercular deposit, which may give rise to an infection of the knee-joint and articular white swelling. As the upper surface only of the tibia is included within the synovial sac,

a tubercular deposit here usually finds an extra-articular outlet, and so the joint is saved. In some cases the tubercular deposit exists, as in Albert's case, in the patella. Every surgeon of much experience must, it is stated, have observed an instance of a sinus over the anterior surface of the patella leading down to bare and carious bone. The joint, in such case, is usually swollen, and sooner or later destructive disease of the whole joint is developed. A case of this kind would seem to be one well adapted for the treatment suggested by Volkmann, since the tubercular deposit is very accessible, and, if allowed to remain, is likely to extend speedily in the direction of the joint.

The subject of Dr. Albert's case was a woman, aged thirty, who in childhood had been affected with keratitis and swelling of the cervical glands. In the autumn of 1876, destructive articular disease had commenced in the right ankle, and in the spring of the following year an abscess had formed over the patella of the same limb. The patient, when first seen by Dr. Albert in September, was suffering from extensive carious disease of the ankle, and presented a small fistulous orifice in front of the knee, through which a probe could be passed down to bare bone in the patella. After amputation through the leg in November, there was a considerable increase in the amount of discharge from this opening, and the knee enlarged and became very painful. As the affection of the joint was progressive, and the symptoms were those of fungoid thickening of the synovial capsule; and as the patella was evidently the starting-point of the mischief, it was decided in January, 1878, to remove the diseased portion, or, if necessary, the whole of this bone. A vertical incision having been made in front of the joint and through the fistulous orifice, the patella was exposed, and its inner half, the structure of which was bloodless, soft, and eroded, was removed by means of a chisel; the outer half, as the structure seemed to be healthy, was left *in situ*. The cartilage of the patella remained, but was reduced in thickness and marked by streaks of yellow deposit. The joint contained about three ounces and a half of turbid fluid; and the whole of the synovial sac was found to have been converted into a thick fungous mass. The articular cartilages of the long bones were smooth and white, and all the ligaments were intact. An incision was made into the joint on each side, and a drainage-tube passed through the articular cavity, which was finally cleansed by the injection of a five per cent. solution of carbolic acid. Profuse suppuration commenced in the joint very soon after the date of the operation, and the patient died two months later in a state of extreme anæmia, after breaking down of the left lung and rapid development of general tuberculosis. —*London Med. Record*, Nov. 15, 1880.

Excision of the Cuboid Bone.

The excision of the cuboid bone in confirmed and inveterate club-foot, advocated by Mr. DAVY, has been recently practised successfully by Poinset in a case which he related to the Society of Surgery on the 28th July. This was a case of left talipes varo-equinus in a young girl, on whom an operation was performed, at the age of eight months. The foot was placed in a suitable apparatus; this, however, having been broken some time afterwards, was not replaced, and the deformity was reproduced. Subsequently, at the age of twelve years, a subcutaneous section of the tendons, which kept the foot in its abnormal condition, was performed; but this operation not having succeeded in removing the deformity, M. Poinset decided on performing the extraction of the cuboid bone; the foot was then placed on a gutter. As the result of this operation, which was performed under antiseptic precautions, complete cure was obtained; some months later, walking was easy, and the foot in a good position.—*British Med. Journal*, Oct. 30, 1880.

Midwifery and Gynæcology.

On the Treatment of Puerperal Fevers.

Dr. J. MATTHEWS DUNCAN recently delivered a lengthy address upon this topic before the Midland Medical Society at Birmingham, for the reproduction of which, in view of the importance of the subject, and the well-known ability of the author, no apology is necessary.

Dr. Duncan said: Although only a few years ago it was far otherwise, the remark may now pass unchallenged, that there is no such disease as "puerperal fever," whose treatment is yet my subject for this evening. That name has been for a century in constant use, and indicates, though with deplorable lack of precision, a group of diseases for whose designation it may meantime be, for convenience sake, retained. Whatever designation we may adopt, we experience no difficulty in recognizing the diseases meant, and there is no hesitation in ascribing to them the highest place in importance to lying-in women who suffer and die, as well as to medical men who observe and treat. Their baneful influences, including their mortality, exceed those of any other group of diseases of childbed. It is truly said that childbearing proves fatal to every hundredth mother, and it may be added that, of this fatality, the far greater part is due to these diseases. How enthusiastic does the study of them become when we contemplate the reduplicated danger of mothers who have just borne a first child; how grave and awful when we regard the rapidly-increasing perils of mothers who count their children by numbers that rise higher and higher into the physiologically excessive.

It is misleading to estimate the importance of puerperal fever by death alone. The habit of doing so is easily accounted for. Mortality is a result, plainly and infallibly ascertained and numbered. The modern science of statistics, and the connected statistical arguments deal almost exclusively with death. In most writings it is implied that escape from early death is recovery—an error which it is only necessary to mention in order to insure its recognition. Death is a simple result, final, unconditioned pathologically—an end, to which various pathological routes may guide. So-called recovery is not its antithesis in practice, whatever it may be in theory. In many cases so-called recovery is anything rather than restoration to health; it is merely an escape, more or less narrow, from early death. The escape is generally into paths which lead to health ultimately; often it is into paths which lead to death more or less directly, more or less slowly, and after a lapse of months or even years. Recovery as antithetic to death is a very indefinite matter. Puerperal fever ends in death or in survival of the immediate attack. Such survival may be in good health or in wrecked health, or it may be in grave and progressive disease.

A good deal of undesirable mystery and much of positive error has been propagated on this subject by the long-continued and still persistent practice—a mere practice, now, without any rational basis—of regarding puerperal fever as occurring chiefly in epidemics. In its prevalence it has a seasonal variation, which Buchan and Mitchell have traced, and which closely resembles that of erysipelas; but it has no periods of epidemic raging; or, rather, none have been demonstrated. Individual epidemics of cholera, smallpox, scarlet fever, measles, and other diseases, have been well described; cycles of epidemics of these diseases have been pretty well traced, but no such demonstration or tracing has been made in the case of puerperal fever. Histories of many so-called epidemics have been written, but their descriptions fail to prove the reality of their epidemic character. Were this disease prevalent in epidemics so frequent as authors ask us to believe, we should be able to give from statistical data a complete account

of them in their individual and in their grouped or cyclical characters, but statistics afford no evidence of the occurrence of any epidemic. The group of diseases called puerperal fever is ever with us, its frequency varying slightly, never rising very high, never sinking very low, always governed by an average. This average of deaths in every community is an average of awful calamity, which we struggle to diminish by treatment, glad to escape from the task of encountering the additional evil that would be raised by epidemic prevalence.

In a meeting of practitioners such as this I make these preliminary remarks as a mere exordium, well knowing that nothing is required to heighten your sense of the interest and importance of the subject. Medical studies do not blunt the sensibility or harden the heart. Who is there so callous as not to be moved by the enthusiasm of a physician when he stands at the bedside of a young wife suffering, and, perhaps, dying, in giving life and joy to others? All of us are frequently in this responsible position, and I dare to say that none of us feels quite satisfied in it. There is not the vacant, hopeless, observation of acute hydrocephalus, nor the melancholy soothing of cancer, but the restless care of a fever, the watching narrowly with a view to judicious interference, watching, well done in proportion to the depth of knowledge and the quickness of intelligence and the warmth of sympathy; interference, judicious in proportion to the wisdom and experience and skill of the watcher. The wisest feels most deeply the want of more knowledge. The most experienced feels most acutely how little power he has to govern a case, how often he is a mere looker-on.

Our topic this evening is the treatment of puerperal fever—how to interfere judiciously, how to govern a case, how to conduct mere management. My remarks are thrown into the form of an address, suited, I hope, in some degree, for this occasion. I do not propose to elucidate any special point, to drive home a scientific argument, to suggest a novel treatment. Such are the objects of the communications which will be laid before you during the session. Mine is to give an address according to the invitation with which you have honoured me, not to read a paper. An address has its own useful place in our meetings; but it is never to be forgotten that the work of our societies is not the hearing of addresses, but the attentive listening to, and careful scrutiny of, papers, generally short, and occupying narrow limits, embodying the results of original observation and reflection. An address may be, as this is, an attempt to review the past, and to sketch the present, condition of a great matter.

In puerperal fever, as in most diseases, practice is more based upon theory than upon our often too much vaunted experience. We condemn old practices chiefly because we have new theories. There can be no doubt that this is a just proceeding, if our new theories are not mere fancies but based on increase of knowledge; and accordingly I shall show the connection of our new treatments with our new theories. However flimsy these theories may be, they are our guides, and they delight and encourage the inquiring spirit of the human mind. Cullen and Heberden based their therapeutics on Hippocratic observation. The Hunters and Laennec on morbid anatomy. The moderns specially on histology and chemistry. Bacteria and sepsin rule us to-day, while mere inflammation has lost its supremacy. We do not see in our change of treatment evidence of any change in the disease, but the reflection of our increase of knowledge.

A great old obsolete plan of treatment is not to be regarded as erroneous or bad, and so contrasted with ours. Such plans were not the fruits of caprice, nor the *ipse dixits* of great and famous physicians, but represented the knowledge and wisdom of their times. I have lived long enough to see the gradual decadence of the antiphlogistic treatment of Gordon, with its venesection and leeching and blistering. Heat of skin, rapidity of pulse, and abdominal pain were

the notes of inflammatory disease which was to be attacked and cured if possible. Since these days much confusion of doctrine has prevailed, and there have been many variations of treatment. The view that the disease was a special fever occurring in many forms, such as are described by Ferguson, led to correspondingly various treatments, which were not materially affected by the great phlebitic discovery which in this country we associate with the name of Robert Lee. Indeed, since the days of antiphlogistics, no great therapeutical plan has been common, for no great medical doctrine has prevailed. The profession has relied much on special drugs in the hope of curing rather than treating the disease whatever it might be; and latterly many have devoted themselves to treating symptoms. Some years ago we heard much of medicines to make the pulse slower; now, in accord with our temperature diligence, we have great stress laid on reducing it.

Living among great physicians, and, as a young practitioner, willingly submitting myself to them, I have seen several changes of treatment. In my earliest days, as a hospital resident and for some time subsequently, while bleeding was a decaying treatment, the great remedy was calomel and opium, and I well remember the improvement in the prognosis which was based on the fortunate but rare occurrence of ptyalism. Gradually the calomel disappeared, because it almost always produced painful and debilitating diarrhœa, and it was replaced by blue-pill. Then the mercurial disappeared entirely; and, under the influence of the teaching of Graves, opium alone became the great resort; and this medicine still keeps its place as a valuable adjuvant in treatment. While its great utility is incontestable, I feel bound to record that I have often seen it act injuriously from its being used in far too large doses. The last treatment which had a passing pre-eminence was the copious administration of food and alcohol. I have been in practice during the whole existence of this modern and still-surviving plan—not a mere spectator or willing subject of older advisers, but taking an active part in the management of grave cases. Experience has taught me that there is no more delicate work in practice than the arrangement of the food and drink; and no part of treatment have I seen so overdone, with the result of producing intense present discomfort, as well as an injurious influence on the progress of the cases. This mismanagement has always been the excessive administration of alcoholic stimulants, apparently under the belief that if a little is good more is better, and that excess is scarcely attainable and not to be feared. The practice was derived from London, and I hope London will have the honour of putting an end to it. Stories of quantities administered, that are scarcely credible, are probably still in all your memories; and I can testify from my own knowledge that they are not exaggerated. Great practitioners boastfully narrated how much they had succeeded in pouring into their patients, and this when they were not in a short critical period of weakness; and the brandy practice and boasting extended even to the treatment of babes!

Although I have seen no treatment by ipecacuanha, yet there have been in my time several "cures" introduced, which have fortunately passed quickly into oblivion. The search for "cures" is, as yet at least, a wild-goose chase. We have a long course to pursue in acquiring intelligence regarding the disease to be cured before we can hope even for a well-established plan of treatment.

It is not uncommon, nowadays, to confine the name of puerperal fever to septicæmia and pyæmia occurring after delivery. It appears to me, however, to be better, even on mere theoretical grounds, to include all the ordinary diseases of the lying-in chamber, which are accompanied by fever, and which may be fatal. In practice we cannot meantime maintain the limitation to septicæmia and pyæmia, because in many cases we cannot be sure of our diagnosis, and because a case may begin as one case and be complicated with another as it advances.

In addition to septicæmia and pyæmia, which are the result of the growth in the blood of certain micrococci having the power of rapidly multiplying, we have sapræmia, or mere poisoning by the chemical products of putrefaction, and we have simple or traumatic inflammatory fever.

Simple inflammatory or traumatic fever is often very alarming on account of the severity of the symptoms, also on account of the extent of the inflammation. There seems to be in addition to the influence of traumatism, in some cases, a temporary inflammatory diathesis, the region of the womb being not the only one attacked, but, in addition, the kidneys or the organs in the chest, or the encephalon, all at once. Sometimes the inflammation attacks the remote parts, while the womb and its neighbourhood are unaffected by it. But most frequently the disease is a parametritis, or a perimetritis which may become so extensive as to form a general peritonitis.

In these cases, when pain is great, the pulse quick and hard, the skin hot and dry, there is generally much benefit derived from the old antiphlogistic regimen and treatment; but now the regimen and treatment are not used with what we may call the rigour and severity of our predecessors. Patients are generally allowed soup daily, in addition to the appropriate quantity of slops, that is, bread and milk and tea. Venesection is rarely practised. I have never used the lancet, nor do I remember hearing of its use for the last twenty years. Leeching is frequently resorted to, the site being above the groins on one or on both sides, that side of course being preferred in which there happens to be most pain. Not fewer than a dozen leeches are applied, and the bleeding may be encouraged to a loss, always only vaguely estimated, and varying according to the hardness of the pulse and the constitutional condition of the patient. The leeching may be repeated if necessary. It is generally followed by well-marked relief of pain and some improvement of the general condition.

While bleeding is most relied upon in the earliest days of the fever, blistering has occasionally a place in the later days. Poulticing is always used. The very painful turpentine stupe is a common application; but in some cases the blister is of great value. It gives much less pain than the turpentine stupe, often, indeed, very little pain, and its effects are not so transitory; besides it causes a copious transudation of serum and subsequently of pus. The blister should be large, even to covering the greater part of the abdomen between the umbilicus and pubes. It should be an old-fashioned rising blister, the emplastrum lyttæ; not such blistering as is nowadays much, and perhaps usefully, employed in other cases, where a blistering fluid raises very rapidly the epithelium, producing little irritation, the skin being only slightly and temporarily reddened. Great irritation and effusion of serum copiously are what is desired here.

Opium is almost always used, and there are great variations in the quantity given, and in the preparation that may be preferred. A good dose of one or two grains at bedtime, to procure sleep, is an almost constant prescription. Advantage is often also found in using the drug during the day if it does not stop the secretions, dry the mouth, and destroy the inclination to take and the power to digest food. In cases where there is much pain, and especially a state of nervous agitation of body and restlessness of mind, the repeated daily use of the drug is most valuable. Many rely upon the copious administration of opium, without any regard to the peculiarities of the case, considering the continued moderate narcotism it produces as the most favourable condition for the patient's recovery. I do not adopt this view of the utility of opium and its preparations, and, therefore, do not press its use as an object in itself, but use it freely when it does not disagree, as a stimulant narcotic to allay restlessness, to soothe pain, to procure sleep.

In severe cases, with much local peritonitic tenderness, a mercurial is advantageously combined with the opium. Many have a special confidence in the calomel, but I hold that it is generally best given as the simple blue pill, about six grains in the course of the day. Or the blue ointment may be applied on the abdomen or elsewhere. Should evidence of hydrargyrismus appear, the further action of the drug is checked by partial or complete discontinuance of it. Many eminent practitioners, especially in Scotland, make no use of mercurials in any form of puerperal fever.

Ever since I began practice there has been less, and still less, of what is, or used to be, called heroic practice in inflammatory cases; and now it is not uncommon to see them indiscriminately treated by opium and stimulants, with poulticing locally. My own judgment of this important practical matter is that a large number do well on this plan if it is conducted not heroically but gently; that, indeed, in many delicate women, with attacks of slight severity, it is the best plan of treatment. But the antiphlogistic regimen and treatment, as I have sketched it, is proper for the majority of cases, demanding of course such modifications as may adapt it to the peculiarities of each individual example.

The next class of cases, that of sapræmia, or of simple putrid intoxication—poisoning not by an organism multiplying in the blood, but by the passing into it of the chemical products of putrid decomposition—is one upon which much light has been recently thrown, and with the most beneficent results in practice. Like the other forms of the so-called puerperal fever, this I shall treat as a separate entity, and it frequently is so. But it may be combined with the traumatic fever of inflammation, and it is especially liable to be combined with septicæmia and pyæmia. Indeed it has long been, and still is, the habit to speak of septicæmia and pyæmia as diseases of putrefaction, but this is a mistake. Putridity of the discharges is not an essential part of these diseases at all, though it often accompanies them. The organisms which cause septicæmia and pyæmia probably take no part in putrefaction. They live in the discharges, and are conveyed or pass into the blood, where they multiply indefinitely. The organisms which cause putrefaction, whether the bacterium termo, or others in addition, may pass into the blood with the putrid fluids to produce sapræmia, but they do not survive, far less grow therein.

We have, then, in sapræmia, when uncomplicated, a very simple problem. Putrid ichor is absorbed or flows through the uterine sinuses, or otherwise, into the circulation. Its poisonous constituents are eliminated rapidly from the blood; for if the supply is stopped the sapræmic phenomena quickly disappear. When once in the blood it does not increase in it, ferment-like, independently of any further supply. Sapræmia is kept up by a continuous supply of the poison. It disappears when the supply from without is stopped. To stop the supply is the problem of cure.

Fetor of the discharges has to be searched for in all cases of puerperal fever. It may be easily discovered by its strength; or it may be concealed, especially if the patient is kept very clean, and if vaginal deodorizing washes are used. The finger, if there is suspicion, or even the whole hand, carefully carbolized, may be passed into the uterus, to find the fetor and its cause, and peradventure to remove them. There may be putridity of discharges alone, but generally there is some decomposing substance, and more than mere bloodclot, a patch of membrane, and probably of chorion, a small bit of placenta, or some hypertrophied decidual mass. Sometimes the putrid fluid is retained *in utero*, and it may be discharged in great gushes, flowing at successive intervals.

Sepsin, or chemical products of decomposition dissolved in water are absorbed by the extensive mucous surfaces of the vagina and uterus, with their lymphatics,

and by the placental and other wounds in the genital tract. Or they pass freely into the uterine sinuses and thus into the general circulation. The result is quick pulse and respiration, high temperature, delirium, and often purging. If the poisoning is slight, symptoms are slight. If the poisoning is by a large dose the symptoms are urgent, and death may result, and this without any added septicæmia to produce the fatal event.

During the currency of the disease or poisoning there is the possibility of a cure, almost sudden, by removing the fetor or stopping the supply of the poison. Nothing is more striking or more gratifying in the whole practice of medicine than this sudden recovery; and, as it is often produced by art, it deserves the name of a cure. A patient in the most alarming condition, apparently within a few hours of death, is appropriately treated, and within a few hours alarm has entirely subsided. It is not in lying-in women alone that such cases are seen; but sapræmia is more frequently observed in them than in others, and the joy of recovery is greater because the foreseen danger is greater, for evident reasons.

An aggravated case of this kind was recently under my care in St. Bartholomew's Hospital, and I shall give you a sketch of it from the notes of Mr. Nall. The largeness of the retained placental mass made the cause of the disease evident and easily discovered; and in this respect it is not like the run of similar cases which are classed under the designation puerperal fever. The recovery in it was so great, so quick, and so nearly complete, as to be scarcely credible. The woman appeared to be at the point of death. It was apparently not worth while to disturb her by treatment. In a few hours after the treatment she was comfortable, and every alarming symptom had disappeared. Yet for some days there was slight recurrence of fetor and persistence of diminished symptoms, but not to such a degree as to cause any suffering or alarm for the ultimate safety of the patient. Were the case not a typical one I should not take up your time with it.

A. E. was delivered naturally of her second child on June 8th. Flooding occurred after the birth of the child, and slight blood loss continued for seven days. Then the lochia became fetid. On the eighth day she had rigors, which were repeated daily. She was brought into the hospital on the tenth day, and was delirious during the night. On the eleventh day of her lying-in, when I first saw her, she had no complaint of pain, was pale, sick, frequently vomiting, troubled with diarrhœa; the uterus tender; breath sweet; respiration hurried, 44; pulse 146; temperature 104.2°; copious flow of stinking lochia. A piece of placenta was removed from the vagina. Under the influence of chloroform the hand was introduced into the uterus, which was soft and easily admitted it, and adherent placental masses were removed, some small shreds being left after many had been separated by volsella. The whole genital tract was then washed out by copious injections of carbolic lotion (1 in 30). Ergot of rye was administered, and the uterus was washed out every four hours during the day. The report of the next day bears that she had a good night without delirium, that the bowels had been twice moved, the motions being thin, yellow, and offensive. The discharge was slight and slightly fetid; the breasts were tender and swollen; the pulse had fallen to 100, the respirations to 36, and the highest temperature was 101.4°. The whole aspect of the case had changed from despair to hopefulness. Ergot was continued for some days, and the carbolic washings as long as any trace of fetor was found. Recovery was uninterrupted; indeed, it may be said there was no process of recovery, there was only convalescence. Such a progress is not seen in any other form of puerperal fever. The theory of sapræmia accounts for the rapid cure, while the theory of the other forms of puerperal fever explains their gradual advance from bad to worse, or to recovery.

Sapræmia is treated earnestly, even heroically if necessary, with a view to its own cure, and with a view to the prevention of the complications, inflammatory, septicæmic, or pyæmic, which it is very likely to bring in its train. Heroic treatment may be required to reach the remotest part of the genital tract in search for decomposing matter, or to ascertain that there is nothing but putrid lochia in the case. Mere vaginal washing may suffice, or intra-uterine washing, or the volsella may be passed into the uterus to grope for the decomposing structure, or with the same view a finger or fingers may be passed, or even the whole hand; and it may be necessary to dilate the cervix preliminarily. Most of this may be done without an anæsthetic, but where the hand is to be introduced into the vagina, the previous induction of anæsthesia is desirable.

The lotion which I always use is the carbolic, of the strength of 1 in 40, or occasionally 1 in 30. It is used tepid or warm. In conducting the operation it is necessary to be very gentle, to avoid the introduction of air into the passages, and to see that the fluid runs out freely. If the os uteri externum and internum are not widely open, a pipe with double current should be used. The whole proceeding should cause little or no pain, and, for an ordinary washing, a pint or a pint and a half may be passed. But if the discharges are copious and fetid, more may be required, and the rule is to continue the injection so long as it comes away foul or perceptibly fetid. Of course, a bowl is to be so used as to receive all the lotion as it is discharged, in order to save the bed-linen from being wetted. When the uterus is washed out the medical attendant conducts the operation, but vaginal washings may be left to the nurse. The washings are to be repeated from twice to four times a day if the fetor persists in the discharges. After the fetor is suppressed twice a day is sufficient. If the discharges become natural, and if the symptoms of sapræmia disappear, the washings are stopped. In any case they are required only for a few days.

These antiseptic washings constitute the great or essential treatment of sapræmia—a treatment, as already said, so direct in its action, and so successful, that is may be called a cure. Though these washings have been described by ancient authors, and though they were recommended by Harvey and by Baudelocque, it is well known to you that no such practice was in use among us till the antiseptic theory of treatment was promulgated. Yet they are not covered by the antiseptic theory, for you know it was based on the presence of bacteria which passed into the blood, and the antiseptic treatment was planned to destroy them or prevent them reaching the wounded surface. Here we use antiseptics not with these views, but to remove and arrest putrefaction, with a view to stopping the supply of a chemical, not a living, poison, the product of putrefaction, which enters the blood and endangers the constitution.

Besides the washings out, a case may demand many attentions, and cares too varied and too uncertain of occurrence for me to enter on them here. But to one I must allude as probably directly useful. It is the administration of ergot. A drachm of the liquid extract, in divided doses, should be given daily for a few days. The object of its use is to induce permanent contraction of the uterus or uterine retraction. This diminishes the uterine cavity, in which the discharge accumulates; it thus also lessens the surface absorbing the putrid poison, and the contraction of the walls of the organ may to some extent prevent the passage of the fetid fluid along the vessels into the circulation. Of course, should it be desirable, the drug may be given hypodermically, ergotin being used instead of the liquid extract.

Perhaps I have made the pathology of sapræmia too simple; for, in addition to what I have said, it is necessary to add that fetid lochia do not always poison

the constitution. They generally do so, but not invariably. They may flow in intense putridity, and yet be apparently not absorbed, as is generally the case. Why the putrid ichor is in some cases not absorbed I shall not here attempt to explain.

I know no reason why septicæmia and pyæmia should be called *real* puerperal fever, yet this is a common mode of speaking. The simple inflammatory fever, and the sapræmic fever, are not less really fever, nor less really puerperal. Probably the notion arises from the fact that grave cases of fever after delivery are for the most part septicæmic, or pyæmic, and that the great majority of the deaths in childbed is produced by these diseases. There has always, indeed, been a tendency to regard puerperal fever as desperate, or almost certainly fatal. I can remember well the saying of an eminent physician, with whose retrospective diagnosis many agreed, that if a case recovered it was not one of real puerperal fever. Probably he did not mean his words to be held as strictly true, but to express his sense of the hopelessness of such cases. This disheartening opinion should not be entertained, for it is not based on ascertained truth, and it induces despondency and feebleness in treatment which are prejudicial to the thorough management of a case. The pyæmic cases with their embolism, inflammation, and abscess, are more dangerous than the septicæmic, but even in pyæmia there are numerous recoveries. Every one has heard of rare and marvellous convalescence in pyæmia, even after several joints have suppurated; but these are very far from being the only instances. Many less severe cases survive the disease.

I may consider simultaneously the treatment of these two diseases. They are often combined, and their treatment is identical, if we except such surgical interference as is sometimes required in cases of pyæmia, a department into which I do not propose to enter. I have said that pyæmia and septicæmia may be combined, and while this is probably a frequent occurrence, it should also be remembered that all the forms of puerperal fever may be simultaneously present in one case. The separate consideration of simple inflammatory fever and of sapræmia is demanded by their utterly different pathology, and by their distinct indications of treatment. For the inflammatory fever we have some modification of the venerable established antiphlogistic method. For the sapræmia we have the arrestment of the putrid poisoning. For the septicæmia and pyæmia we have no treatment in any sense antidotal or curative in the humblest meaning of that word.

Cases of pyæmia and septicæmia are to be managed rather than treated. The word treatment implies too high an estimate of the physician's powers; or if not too high, at least a too definite view of them. We cannot arrest or even moderate the storm, but we may guide the bark through it. When the organisms producing these diseases are in the blood we cannot kill them, nor do we know any means of certainly controlling their growth. But we may wisely consider the constitutional and local circumstances of the patient, and judiciously interfere to modify them with a view to the patient's survival.

One unsound tree in a forest may be covered with lichen and fungus, and the tree may slowly die, or be killed. But it may survive, and becoming healthy, throw off the morbid growth which endangered it. The organisms of pyæmia and septicæmia find a favourable nidus for development in the weak, the unhealthy, the hopeless, the ashamed, the sad—in those who have been exhausted by a long labour or injured in the course of a severe one. But the attacked do not certainly die. The organisms may grow and grow, and cause death, but they are not necessarily fatal; their growth may be arrested, and they may all disappear. Debilitating and depressing conditions favour their development. Health and strength favour their disappearance. These principles are the foundation of

our management; and experience, daily increasing, confirms the conviction that the foundation is not laid on sand.

Good nursing, careful feeding, prudent stimulation—these are the great points. In all of them there is now progressive improvement. While it is impossible to appreciate with any exactness what we owe to these, no one will deny the comparatively great advantages we now gain by them. It would be out of place to enter upon the subject of nursing here. It is no peculiarity of cases of septicæmia and pyæmia to require good nursing, and the subject is specially referred to in connection with these diseases because, in default of any direct treatment, we specially consider what remains for us to attend to.

On feeding and the use of stimulants I might content myself by making the same remarks as on nursing; but I wish to insist on the great necessity for more attention being paid to the niceties of these important departments. The food and drink should not be left altogether to the nurse. In quality, quantity, and time they should be regulated; and this cannot be done by previously fixed rules, but by directions modified according to the observations daily or hourly made in each individual case. Milk and beef-tea are the staple of the patient's diet, and they may be varied almost indefinitely, to suit minor emergencies as they arise. In regard to food, the general rule is to give as much as the patient can take without evident disorder arising from it. It is seldom that too much is taken, for a common difficulty lies in overcoming the aversion to food.

The use of stimulants requires a little more discussion. At present the favourites are brandy and champagne, and I adhere to the general voice in preferring them—on one condition, that they be really good. At the same time I make no objection to other wines and spirits. Brandy and champagne are common and simple, and, for me at least, it would be only an affectation of refinement to appraise the merits of different wines and different vintages. But I am sure that, in regard to all stimulants, our aim should be to use as little as possible. Often, at least for a time, none at all is required. Occasionally, but rarely, in a crisis of weakness, brandy is to be administered largely. Always the principle holds good that too much will do more harm than too little. I am sure that it is a common error to give too much. Excess of food may be passed along the primæ viæ without entailing any considerable injury; not so excess of alcohol. Food is rarely desired by the patient, while she often wishes alcohol; because, as it is given, it assuages thirst for a time and produces at once an agreeable excitement.

A sketch of the treatment of septicæmia and pyæmia would be bald and imperfect if it were confined to the paramount matters—nursing, food, and stimulants. Great attention has to be paid to the general condition and to the state of health as indicated by prominent symptoms. Iron and quinine are now frequently administered, and with great advantage; and what a change of view does this imply if we look back to the days of Gordon, or even of Fergusson? I can well remember the astonishment and unsettlement of mind produced by the recommendation of Hamilton Bell to use the old tincture of the muriate of iron in erysipelas, and I frequently witnessed the earliest employment of the same remedy in the cognate diseases now under discussion, chiefly by the advice of the elder Begbie. It was always the custom to combine bitters with the iron, but now the regal bitter, quinine, is used, not only as a stomachic vehicle, but with the direct purpose of reducing the temperature whose regular observation helps so greatly to guide us now—a chart unknown in the days of Bell and Begbie. Besides quinine and salicin, the influence of cold is now familiarly resorted to to reduce temperature when it rises above 102° or 103°, and this is done with the result of giving comfort and securing probably real gain. Many physicians, Schroeder, Osterloh, and Spiegelberg, in Germany, and especially Playfair in this country, have used the

cold bath to reduce temperature when it is very high; but I have no experience with it. Temperature does not long remain high in this disease, varying greatly and often rapidly; and for keeping it moderate, quinine or salicin, in large doses, with regulation of the heat of the room, of the bedclothes, and of tepid sponging, are generally sufficient.

Ice is often taken internally against thirst, and it is a delicious mouthful; but the craving thirst is not relieved. The dose is repeated and repeated in vain. For the relief of thirst, the old remedies, such as toast-water, have more real value. But the urgency of thirst is minimized by the proper management of the case. At least, I can have no doubt that in the days of what I call the excessive use of wine or brandy, or of opium, we heard a deal more of the suffering from thirst than we do now.

Ice is much used to arrest vomiting, which is so common a symptom of the peritonitis of puerperal patients, and it is sometimes effectual. For this distressing symptom remedies are numerous, and their largeness of number is evidence of their uncertain action. The best is of course that most used—the hydrocyanic acid and bismuth mixture, without or with morphia.

With or without sickness and vomiting there may be flatulence, and it is sometimes so great as to embarrass the heart and lungs. In extreme cases relief has been afforded by letting off the air by a small trocar and canula, but of this proceeding I have little experience. The remedies which I have found of most use are charcoal, in teaspoonful doses, given in water once or twice daily; or turpentine, in ten-drop doses, given in water or some simple vehicle, three or four times daily.

The hot linseed-meal poultice is almost always a grateful and useful application to the hypogastric region, relieving pain and promoting the lochial flow. Besides, when the skin is hot and dry, it is a valuable diaphoretic.

Opium in some form is invariably administered, and almost always with advantage. Occasionally, indeed, it produces great mental disturbance and uneasiness, or vomiting, or dryness of tongue; and, in such cases, if a change of the preparation does not bring better results, the medicine may have to be given up, or used only to produce sleep. Indeed, apart from any injurious effects, it is often a good plan, when pain is not urgent, to give it only to secure a good night. But generally it is given repeatedly during the day, either to relieve pain or with a view to its soothing and supporting rather than narcotizing action.

Opium and other remedies are also often used against diarrhœa, and in this way much good may be done. But it is necessary to pay much attention to this purging, generally of thin highly-coloured dejecta, for undoubtedly it often should be encouraged rather than checked; and, perhaps fortunately, it is often not easy to check it. The physician should see all the motions, so as to justly estimate their quantity and character, and he should not regard it as his duty to try to check free and even copious evacuations, or to get the stools in a formed state. He will be guided in his judgment on this point by the strength of the patient and the amount of food consumed.

During the whole course of the disease the regular flow of the lochia is anxiously looked for; and, should they be suppressed, an attempt is made to bring them back by hot fomentations to the vulva and hypogastrium; for it is naturally regarded as desirable that there should be lochial discharge, and that it should not be retained. But, besides its mere flow, the character of the discharge, especially as to fetor, is scrutinized. If there is fetor there is probably sapræmia complicating the septicæmia or pyæmia, and this fetor is treated by antiseptic lotions, as already described. But fetor of discharges forms no part of septicæmia or pyæmia. The bacteria or micrococci of these diseases flourish when there is

no fetor. At present, however, such is the enthusiasm for antiseptics, that it is considered desirable to have the womb well washed out once or twice daily by carbolic lotion, even when there is no fetor; and meantime I consider it good practice to do this twice daily while there is urgency, if the discharges are not quite healthy in all respects. The intra-uterine washing cannot work upon the infected blood circulating everywhere in the body, and carrying with it the baneful organisms, but it can keep the wounds clean; and, if the womb or vagina is a nursing-ground for further supplies of these organisms, then by the antiseptic washing the nursery is destroyed. The further supply of the contagium vivum is stopped, for the micrococci are killed by the carbolic wash.

Such, gentlemen, is an outline of the treatment of a group of terrible diseases. How imperfect it is, no one can feel more strongly than I do. It is not a fixed treatment, but the treatment of to-day. Were I the wisest therapeutist, and had I the best rhetoric, my description would still be imperfect; for no one can describe, with a near approach to perfection, what is imperfectly known and very dimly understood. But the variations of health and constitution, of complications, and of other conditions, are so numerous that a perfect theory or system of treatment would not carry with it directions for every individual case. Boundless scope, after all, would be left for intelligent interference of the practitioner warmed into zeal by a kindly sympathizing heart.

Meeting with these puerperal diseases, the practitioner dare not fold his hands in apathy and inaction on account of the incompleteness of his knowledge. No one would listen to him were he to proclaim that all our experience and all our laboriously acquired information had yielded no fruit for the benefit of suffering women. He is face to face with great and terrible danger, yet his position is not one of imminent peril to himself as in the case of a soldier, who, like him, has to meet unexpected combinations and unforeseen difficulties, and who, whether he has little or much knowledge, must act and that at once, for in boldness there is safety, in delay there is only disaster; and experience has amply demonstrated that no case is to be utterly despaired of till the moribund state supervenes, however severe and complicated it may be.

We have said that puerperal fever affects especially the weak, the unhealthy, the hopeless, the ashamed, those who have been exhausted by a long labour or injured in the course of a severe one; and there is no need to expatiate on the great field here opened up for the beneficent activity of the physician. To strengthen, to heal, to encourage, to console, to manage labour, to reduce injuries to a minimum, are all objects to be kept in mind; not indeed with a view only to the treatment of puerperal fever, but in order to its prevention. It is a trite saying that prevention is better than cure, and I think there can be no doubt that more suffering is avoided and more lives saved on this principle than by treatment; and I feel impelled to say a few words on this subject.

The prevention of simple inflammatory and of sapræmic fever demands no special consideration here; it is the prevention of septicæmia and pyæmia, or of contagious puerperal fever, that is generally in view when prophylaxis is spoken of, and few subjects are at present more discussed. The late trials of midwives for spreading puerperal fever, and the reiterated attacks on maternity hospitals, are familiar to all; and I believe all will admit that we want much more light and more wisdom in our dealings with these matters. They are not identical, for the propagation of puerperal fever in a hospital involves considerations which have no place in its propagation in a private or out-of-door dispensary practice. Hospitals are the seat of endemics of fearful character. The house becomes tainted, and every lying-in woman in it is in great danger from the infection. Fortunately, the infection does not become so intense as to affect all, but such a

degree of intensity is quite conceivable. In an ordinary dairy no vessel of milk escapes the action of the bacterium lactis; every dish becomes curdled. In home practice the infection reaches patients only sporadically; the disease, however, occasionally dogging the footsteps of an individual practitioner. There are no epidemics, no prevalence of the infection over countries. A lying-in woman can easily find a safe home. The analogy of the curdling of milk does not apply here, for it is difficult to find a place where there is no bacterium lactis where milk does not curdle.

Against the dangers of both hospital and home practice we find some degree of protection in antiseptic midwifery, a great practical subject which I have discussed in an address lately given to the Medical Society of London. Antiseptics have, as yet at least, but little to do with the treatment of the infectious forms of puerperal fever; they avail greatly in the prophylaxis. This has been well exemplified in the case of hospitals. In private practice the protective power is not so easily demonstrated; yet I believe the plan is there also invaluable, rendering the patient comparatively safe and practically excluding all danger of infection by the careful accoucheur.

Ventilation and cleanliness were, up to the present time, the great resorts of medicine against endemics of puerperal fever, and they had little and only temporary effect. They are, however, even now justly valued very highly; but, with antiseptics, we come into closer quarters with the enemy we have to subdue, and have a weapon of greater potency, and consequently we have more success. In spite of all our prophylaxis, however, puerperal fever prevails. The enemy succeeds in the attack and the physician has to make every effort to rescue his patient by treatment.

Although we have at present no prospect of being able to stamp out the infectious forms of pueperal fever or of reducing them to comparative insignificance, there is yet, even as to the attainment of these great ends, some ground for hope arising from the success of scientific investigations. Vaccination seems destined only to a brief further protraction of its splendid and useful isolation and of the mystery of its operation. The results of Pasteur's researches on the cholera of the domestic fowl and of Toussaint's and Greenfield's on anthrax show how a contagium vivum may have its potency diminished, or nearly annihilated, by methods having a strong analogy with those employed to reduce the potency of the variolous contagion. If one contagion can be so modified, we are led to ask, Why may not also that of puerperal fever be likewise? There are other researches by Greenfield and Buchner which justify the philanthropic hope that with lapse of time the deadly characters of the organisms of septicæmia and pyæmia may be changed into others more innocent. Such anticipations are little more than mere indulgence of the scientific imagination; but they are far from being useless or foolish, though to the merely practical man they may appear so.

The idea suggested by the researches of Pasteur, of Toussaint, of Greenfield, and Buchner may prove to be mere *ignes fatui*, but may, on the contrary, prove to be true guides. It is by following out such ideas, verifying or disproving them by new investigations, that progress is made in science. Progress in science is a fountain of purest pleasure to its promoters and of widespread beneficence to mankind.

The Society whose new session I have the honour to inaugurate is devoted to the advancement of science, and I dare in conclusion to suggest to every busy medical man here that he should make some department of it, perhaps a very small department, his peculiar study. By so doing he will keep a special perennial joy in his life of toil; he will be, if not a discoverer of new truth, at least a diffuser of it; he will be a useful and honoured member of this Society, he will

contribute to the elevation of medicine into a more and more useful profession, and of his medical brethren into a higher and higher position.

The healthy and diseased human body is not the greatest matter in the universe of things. Our profession acknowledges that there are others to whom, in respect of the value and grandeur of its aim, it willingly bows. But medicine offers more than sufficient scope for the greatest efforts of the greatest minds. It is for us to contribute to its prosperity and progress. *Floreat res medica.*—*Lancet*, Oct. 30, and Nov. 6, 1880.

On the Treatment with Alkalies of a little known Cause of Sterility.

CHARRIER, of Paris, calls attention (*Bull. Gén. de Thérap.*, Nos. 11 and 12, 1880) to an acid condition of the utero-vaginal mucus as a cause of sterility. He states that many women who are quite healthy, whose genital organs are perfectly normal, and who are married to healthy husbands remain sterile. The cause of this is frequently an acid condition of the uterine and vaginal mucus, which may be proved directly by the use of litmus paper. This condition is an absolute prevention of conception, because the spermatorrhœa die immediately. Accordingly, if the woman's mucous secretions give an acid reaction, she continues sterile. By treatment with alkalies, alkaline drinks and baths (Vichy water), and alkaline injections (1000 parts of water, sulph. of soda 90 parts, white of egg 1 part), the disease may be removed and conception follow. This, according to the author, explains the frequently incomprehensible results and numerous strange successes that follow the use of alkaline springs in sterile women. Two successful cases are given in illustration of the author's views. Professor Pajot also expresses himself as in agreement with the author's views.—*Edinburgh Med. Journal*, Nov. 1880.

Congenital Abnormality of Uterus simulating Retention of Menses.

Dr. BRAXTON HICKS related at a late meeting of the Obstetrical Society of London (*Lancet*, Nov. 27, 1880), the history of a patient, aged twenty-four, who had never menstruated. About twelve weeks ago she had severe pain in the right hypochondrium, lasting about six weeks. About the same time she noticed an increasing swelling in the lower abdomen, and recently tension had become severe. On admission a tumour was felt reaching above the umbilicus, tense and semi-fluctuating, causing distress and œdema of the legs. She had not distinctly suffered from monthly increase of distress. The vagina was nearly of normal length, ending in a kind of transverse depression, beyond which was felt the tumour, exactly resembling the uterus distended with menses. The author had had such a case, apparently exactly similar, the very extremity of the vagina and os uteri being closed. The patient was therefore placed under chloroform and a trocar plunged in, where a depression like a dilated os beyond the closure could be felt. Nothing but a little bloody serum flowed. The sound was then passed up into the centre of what seemed to be the uterus, but still no sign of menstrual fluid. Further interference was then abandoned, the tapping having been done antiseptically. In the night she became feverish, and died about thirty hours after the tapping. Post-mortem examination showed that there were neither uterus nor ovaries, but a large cyst attached to the upper end of the vagina; walls very irregular within, smooth without. It was half filled with a cheesy white matter, and the rest with dark grumous material. The wall above was thinned and perforated in two or three places, where the contents, in a fetid condition, had escaped into the peritoneal cavity. The trocar had passed through two layers of peritoneum. Probably the operation had only hastened the rupture.

A report by Dr. GALABIN on the Microscopic Structure of the Cyst was appended. The outer wall of fibrous tissue was only about one-twelfth of an inch thick. The soft material within was made up of round cells, longer than leucocytes, having a fibrillar reticulum amongst them. It was to be regarded as a soft sarcomatous growth.

Dr. ROUTH said that the practical point which came out was, that in another case the aspirator should be used to see the nature of the fluid, if any, before a trocar was employed.

Medical Jurisprudence and Toxicology.

Antidotes.

The following collection of antidotes is taken from the *Allgemeine Wiener Medizinische Zeitung*:—

Morphia. Sulphate of copper, 1 gramme; distilled water, 40 grammes, for an emetic; half to be taken at once and the remainder in five minutes, if necessary. To be followed by strong coffee, and then every five minutes by tablespoonful doses of a mixture made by dissolving 4 grammes of tannic acid in 50 grammes of simple syrup.

Opium. As for morphia.

Veratria. As for morphia.

Savine. As for morphia.

Fungus-poisoning. As for morphia.

Stramonium. As for opium. May be followed by a hypodermic injection of morphia.

Nicotine. For the sickness resulting from tobacco-smoking, vinegar, 50 grammes; simple syrup, 50 grammes; water, 200 grammes; half to be taken at once, and then a tablespoonful every five minutes. For accidental poisoning by nicotine, same as for morphia. Also tannic acid, 4 grammes; syrup, 50 grammes; distilled water 200 grammes; a tablespoonful every five minutes.

Phosphorus. Sulphate of copper, 1 gramme; distilled water, 40 grammes; half to be taken at once, the rest in five minutes, if necessary. Then oil of turpentine, 30 grammes; white and yolk of two eggs; simple syrup, 50 grammes; peppermint water, 250 grammes, for an emulsion, to be well shaken; one tablespoonful every half hour until a fourth part has been taken, and then a tablespoonful every hour.

Burns by Phosphorus. Nitrate of silver, 2 grammes; distilled water, 20 grammes; to be used as a lotion.

Petroleum. Oily and mucilaginous drinks to be taken frequently.

Lunar Caustic. Common salt, 20 grammes; water. 300 grammes; half to be taken at once, then a tablespoonful every half hour with oily mucilaginous drinks.

Strychnia. Tannic acid, 3 grammes; syrup of marsh-mallow, 60 grammes; distilled water, 140 grammes; a tablespoonful every five minutes. Then chloral-hydrate, 4 grammes; distilled water, 100 grammes; a tablespoonful every half hour.

Sausage Poisoning, and Poisoning by Decomposing Meat. Sulphate of copper, 1 gramme; distilled water, 40 grammes, for an emetic; half to be taken at once, and the remainder in five minutes, if necessary. With this may be given ether, 2 grammes; tincture of opium, 10 drops; distilled water, 150 grammes; a tablespoonful every half hour.

Ergot. As for sausage poisoning.—*London Med. Record*, Oct. 15, 1880.

MEDICAL NEWS.

Milk as a Carrier of Disease.

The tireless inquisition which sanitarians are ceaselessly prosecuting into nature's methods of propagating disease has seldom been rewarded with a more valuable discovery in a more unpromising field, than that in regard to the portability of certain infectious maladies by means of milk; a fluid which from prehistoric times has formed so large a part of the food of juvenile humanity, and has as a rule, except on the score of aqueous dilution, been implicitly trusted by mankind.

The peculiar readiness with which milk absorbs disagreeable odours and flavours has long been a matter of common observation, but it is only within the past ten or twelve years, that its power of taking up the germs or disease poisons of several contagious affections and transplanting them from their original site to the congenial soil of some uninfected human organism, where they could flourish with renewed vigour, was detected. Doubtless much of this capacity for evil which is possessed by milk is due to the very circumstance of its obtaining access to infants and young children who have not been protected by previous attacks of scarlatina or enteric fever, but its chemical constitution being that of a dilute watery solution of highly complex nitrogenous matter, renders it almost as favourable a medium for the growth of bacteria as Pasteur's fluid itself, so that believers in the germ theory of disease contend its natural composition is peculiarly favourable on this account to the extension of its sphere of deleterious influence. Be this as it may, however, there is no question that more than a dozen localized epidemics of typhoid fever, scarlet fever and diphtheria (some of them affecting hundreds of individuals), the origin of which would otherwise have been shrouded in mystery, are now satisfactorily traced to dairy farms occasionally many miles from the scene of their deadly operations. In most instances the milkmen have strenuously denied that any typhoid fever poison could have found entrance to milk from the wells in which it was proved to have existed upon their premises, except during the process of washing out their milk cans, but knowing as we do how profitable and how difficult of detection is moderate aqueous adulteration, it requires all an optimist's faith in poor humanity to give credence to their statements.

We are led to call public attention to this subject at the present time by the fact that several recent English medical journals come to us bearing accounts of new epidemics, attributable to the infection of milk tainted with the poisons of typhoid fever, scarlatina, or diphtheria. Thus, for example,

at Southport, one case of typhoid after another was announced to the municipal authorities until in about two weeks a total of twenty-eight was reached. Such a rapidly invading epidemic demanded of course energetic measures for its repression and a careful inspection of the various dwellings in which the victims had been attacked was undertaken. The health officers found, however, to their surprise, that with two trifling exceptions these premises were all in good sanitary condition; but further investigation disclosed the fact that in every instance milk had been served to the families in which the typhoid fever had occurred from a particular dairy some miles distant, and upon the grounds of this dairyman was discovered a well horribly polluted with soakage from a filthy cess pit near it. In the words of the chairman, "chemical analysis showed that it was nothing but liquid sewage and calculated to spread disease wherever its influence extended," and the proof that this foul infecting material had been accomplishing the work for which it was so well "calculated," is met with in the circumstance that on stopping the milk supply from this dairy the epidemic ceased to spread, although not before two of the cases previously attacked had resulted fatally.

The infectious material, when scarlatina and diphtheria are conveyed by milk, probably falls into the fluid whilst standing in open vessels, or is rubbed off, attached to the epithelial cells of the epidermis during the process of milking in such a way as to gain access to the milk. In an example of this kind, recently the subject of judicial action in England, a medical officer of health stated before the magistrates that seven cases of diphtheria had occurred in his own practice, and that during inquiries made for the purpose of tracing the origin of the disease, he had heard of other instances, all of which as well as his own had been supplied with milk from the same establishment. Acting upon this hint he proceeded to examine the dairy from which the milk was obtained and found that a child was dying from malignant diphtheria on the premises, so that this case was, it seemed highly probable, the starting-point of the whole outbreak of the malady.

Still another fresh illustration of the dangers we are now considering is reported from the town of Dundee in Scotland, where an extended epidemic of scarlet fever is stated to have arisen among families supplied from two particular dairies. On careful investigation scarlatina was found to have been actually prevailing in the families of the dairymen in charge of these establishments before and at the time the other cases made their appearance.

Of course the only way to obtain a reasonable security for our families against this form of poisoning would be to follow the example of our English cousins and establish by law a system of thorough inspection of dairy farms, dairies, and cow-stables having special reference not only to the health of the animals and of their care-takers, but also to the state of

the wells from which the water for washing out the milk cans, pails, etc., is derived. How common it is to see even on well-kept farms the water supply for these and similar purposes obtained from the barn pump which for convenience in cold weather stands under the cow shed or inside the farmyard, where it is at all times liable to furnish a liquid dangerously contaminated with excrementitious matters from both man and beast. As a substitute for such legal supervision the most feasible plan would probably be for citizens to unite together into limited associations, which could employ experts to investigate and keep watch over the sanitary surroundings of dairy farms patronized by their members. Although such undertakings might be at first rather expensive, yet when the mere cost of a dozen cases of typhoid fever is considered, there is no doubt that the outlay would be a truly economical one, even if looked upon from a pecuniary point of view only, without estimating the far more important saving of human life and suffering. In cases where such co-operative societies could not be organized, or whilst travelling, it would be advisable to use only milk which has been thoroughly boiled for a considerable length of time.

—

Symmetrical Neuralgia in Diabetes.—Dr. Worms, of Paris, has called attention to the occurrence of symmetrical neuralgias in an advanced period of diabetes. He has recorded two examples—one affecting the sciatic nerve, and one the inferior dental—and believes that the symmetry of the affection is a characteristic of this form, as also is its peculiar severity. It does not yield to the ordinary treatment of neuralgia—quinine, morphia, bromide—and the pain varies in intensity with the amount of glycosuria.—*Lancet*, Oct. 30, 1880.

—

Simultaneous Fracture of both Patellæ.—M. de Beauvais related at the Paris Société de Médecine (*Union Méd.*) an example of this rare occurrence. A man, thirty years of age, and apparently in good health, was engaged in the game of leap-frog, and, having struck the ground with his feet, when on the point of springing forwards he felt as if he had received a blow on the legs, and heard a crackling sound. He fell on the ground, believing that some one had struck him. On his being carried to the hospital, a transverse fracture of each patella, with a separation of not more than two centimetres, was found to exist. This was effected by the violent contraction of the extensors. The patient had had rheumatism with cardiac complications formerly.—*Med. Times and Gaz.*, Oct. 9, 1880.

—

A New Method of Preserving Raw Meat.—A new and apparently most valuable method of preserving raw meat, discovered by Prof. Artimini, of Florence, bids fair to supply a long-felt want, and to have an appreciable effect upon our markets. According to a report by Professors Barff and Mills, of Glasgow, and Dr. Stevenson, of Guy's Hospital, meat six months old was found to be perfectly sound and good, the muscular fibres unchanged, and the nutritive properties unimpaired. The material employed is stated to be less expensive than salt, and not only wholesome, but pleasant to the taste.—*Med. Times and Gaz.*, Oct. 9, 1880.

A Triple Ovary.—Dr. Keppeler, on the occasion of his sixth ovariotomy (all successful), found a third ovary, with its corresponding tube, completely developed. According to Rokitansky and Klebs, no such circumstance has hitherto been observed.—*Med. Times and Gaz.*, Oct. 9, 1380, from *Allg. Wien. Med. Zeit.*, Sept. 7.

—

Chian Turpentine and Cancer.—The Medical Committee of the Middlesex Hospital recently passed unanimously the following resolution: "That, as the results of a prolonged and careful trial of Chian turpentine in the treatment of cancer prove the drug to be quite useless as a cure for that disease, directions be given to the dispenser not to obtain any more of the drug for the cancer patients." —*Med. Times and Gazette*, Nov. 27, 1880.

Mr. Henry Morris, Surgeon of the Cancer Out-Patient Department of the Hospital, in a contribution to the *Lancet* (Nov. 27 and Dec. 4, 1880), on his experience with the use of the drug says he is "not able to report that there is a single symptom over which the drug seems to exercise even frequently, not to say constantly, an influence. It cannot be relied upon to assuage pain, to diminish or alter the character of the discharges, to check hemorrhage, or promote the destruction of the growth by ulceration or sloughing," and that the conclusion is forced upon him "that as a cure for cancer Chian turpentine is utterly valueless."

—

Medical College of Virginia.—This institution has just sustained a serious loss in the resignation of its talented Professor of Surgery, Dr. Hunter McGuire, of Richmond.

—

New Sanitaria.—A new winter resort for invalids has been recently established at Lakewood, a village on the line of the New Jersey Southern Railroad, about nine miles from the ocean and fifty from either Philadelphia or New York. The village is situated on the edge of extensive pine woods through which have been constructed numerous excellent roads. The soil is dry and sandy. The house is new and handsomely furnished and the cuisine is unexceptionable; each bedroom has an open wood fire. For the benefit of invalids in winter the verandas have been inclosed in glass.

A sanitarium has also recently been opened at Monterey, about 125 miles from San Francisco. The "Hotel del Monte" is a large building, with all the modern appliances of a first-class hotel, and accommodates 400 persons. It is situated in a grove of 106 acres of oak, pine, spruce, and cypress trees, and is within a quarter of a mile of the Bay of Monterey, with a fine sloping, sandy beach, admirably adapted for bathing. The climate is represented as charming, corresponding to our "Indian summer," with an equable temperature varying in the winter months from an average of 49° to 55°, and with a summer temperature averaging about 6° higher. It offers, in addition to beautiful and varied scenery, boating, fishing, and hunting to the sportsman.

—

Mr. Lister.—The Royal Medal of the Royal Society has been conferred on Professor Lister, in recognition of his important physiological services, and the advance in surgery due to his studies and application of antiseptic principles.

Mr. Lister is spoken of as the next President of the Clinical Society of London.

A Veteran Professor.

M. Chevreul has completed his fiftieth annual course of lectures on the Application of Chemistry to Organized Bodies, at the Museum of Natural History. M. Chevreul is in his ninety-fifth year and is still an indefatigable worker in the laboratory. His father attained the advanced age of one hundred and ten. The American Association for the Advancement of Science, during its recent session in Boston, sent a congratulatory telegram to the eminent savant, expressing the hope that he may be enabled to continue his labors until the end of the century.

—

Langenbeck's Seventieth Birthday.

In Berlin, on the 9th of November, a highly interesting celebration was held on the occasion of Professor Von Langenbeck, the distinguished German surgeon, on that day reaching his seventieth year; and, both from the military and the civil authorities, and from friends both near and far, he received an ovation which falls to the lot of few. The day began by a *reveillé*, played before his door by the band of the Third Regiment of the Imperial Guard. Soon afterwards arrived private letters of most affectionate greeting from the Emperor of Germany and the Empress. The Crown Prince sent a telegram of congratulation from Wiesbaden, in his own name and that of his wife. The Emperor of Austria sent the Grand Cross of the Order of Francis Joseph; the King of Saxony, that of the Order of Albert. The Medical Faculty of the University of Berlin appeared as a body, and addressed Langenbeck through their Dean. A deputation also waited on him from the Frederick-William Military Medical School, whose Director-Surgeon-General (Schubert), in presenting a laurel wreath, addressed to Langenbeck the following words: "Ever since your arrival as Professor, in Berlin, our institution has rejoiced in your instruction, and we have all sat at your feet. In peace time, as in war, you have been our guiding star; and there is scarce a single doctor, either in our army or our marine, who is not personally indebted to you for surgical knowledge and power." A number of his former pupils, now professors in the universities of Germany, presented an elaborate address. Amongst those present were Professor Esmarch of Kiel, Billroth of Vienna, Schönborn of Königsberg, Lücke of Strasburg, Trendelenburg of Rostock, Hueter of Griefswald, and others. Count Moltke paid personally his respects, as well as a host of other distinguished persons. A few cordial and appreciative words, engrossed on vellum and signed by the President of the Royal College of Surgeons of England and a number of prominent British surgeons, reminded Professor Von Langenbeck of the high appreciation in which he was held in England.

—

Health of Charleston.—This city is now reported to be very healthy. The dengue had pretty much expended its force before the cold weather set in; since the appearance of ice (November 25) the disease seems to have completely disappeared. A few cases of influenza have been observed—one of them attended with sweatings, but it is doubtful if these were cases of dengue. As far as can be learned, the dengue originated in the northwestern portion of Charleston, about the end of June, and gradually extended. It may have exhibited itself earlier in Key West. It made its appearance at a later date in Summerville, Columbia, and other small towns on the line of the South Carolina Railroad—reaching Wilmington, N. C., where it appeared to a very slight extent and in a very mild form. Augusta, Savannah, Port Royal, and Beaufort were invaded in August and September. None of the Charleston cases, which were uncomplicated, proved fatal.

Diphtheria, which prevailed in Charleston for several years past, has almost entirely disappeared.

—

International Medical Congress, London, 1881.—We have received circulars informing us that the following subjects have been proposed for discussion:—

In Section V. (*Surgery*): 1. Recent advances in Abdominal Surgery; 2. On the surgical treatment of certain diseased conditions of the Kidney; 3. On the recent advances in the method of extracting Stone from the Bladder; 4. On the treatment of Operation of Wounds; 5. On the treatment of Aneurism by the elastic bandage; 6. On the comparative advantages of early and late resection in Diseases of Joints.

In Section VII. (*Diseases of Children*); Medical: 1. The real position of the so-called Rubeola, Rötheln or German Measles, and its relation to Scarlatina and Measles; 2. Syphilis as a cause of Rickets; 3. On the different kinds of Spinal Paralysis and Myelitis in children; 4. The conditions governing the occurrence of Albuminuria and of Paralysis as attendant on Diphtheria, or as Sequelæ; 5. The relationship of Chorea to Rheumatism, with especial reference to the nature of the heart-murmur which so frequently attends Chorea; 6. The forms of Acute Tuberculosis other than ordinary Tubercular Meningitis. Surgical: 1. The surgical treatment of Croup and Diphtheria; 2. The surgical aspect of Tapping for Empyema; 3. Pathology and treatment of Genu Valgum; 4. The treatment of Diseases of the Joints, especially with a view to the prevention of deformity; 5. Treatment of Spinal Curvature, with special reference to Sayre's method; 6. The nature of the so-called Surgical Scarlet Fever.

In Section X. (*Otology*): 1. On the value of operations in which the Tympanic Membrane is incised; 2. On morbid growths within the ear and their treatment; 3. On loss of hearing where the external and middle ears are healthy.

In Section XIII. (*State Medicine*), first day: 1. Measures by which to prevent the Diffusion of different Communicable Diseases from country to country, or within the limits of any single country—*e. g.*, (1) yellow fever, cholera, plague; (2) enteric fever, scarlet fever, measles, whooping-cough, diphtheria; (3) syphilis; (4) glanders, hydrophobia, anthrax. Second day—2. Influence of various articles of Food (not including water) in spreading Parasitic, Zymotic, Tubercular, and other Diseases. Third day—3. Conditions to be imposed on the legally qualified practitioners of one country who may seek authority to practise in another country. 4. Precautions to be taken in medical nomenclature and classification to guard against false statistical conclusions.

These lists are only provisional, and subject to modification. The final lists will be published at an early day. Abstracts of papers to be read before the Sections will be published in May, 1881, in English, French, and German for the convenience of the members.

The Lord Mayor of London has expressed the satisfaction he shall have in doing everything in his power officially to promote the success of the International Medical Congress to be held in London next August, and his intention to tender to it an official welcome on the part of the citizens of London. It is understood to be the intention of the Lord Mayor to open the Mansion House for a State reception of the members of the Congress.

—

To Readers and Correspondents.—The editor will be happy to receive early intelligence of local events of general medical interest, or which it is desirable to bring to the notice of the profession. Local papers containing reports or news items should be marked.

BURNETT ON THE EAR—Now Ready.

THE EAR; ITS ANATOMY, PHYSIOLOGY AND DISEASES. A Practical Treatise for the Use of Medical Students and Practitioners. By CHARLES H. BURNETT, A.M., M.D., Aural Surg. to the Presb. Hospital; Surg. in Charge of the Infirmary for Diseases of the Ear, Phi'a. In one handsome octavo volume of 615 pages, with 87 illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6.

ATTFIELD'S CHEMISTRY—Now Ready.

CHEMISTRY, GENERAL, MEDICAL AND PHARMACEUTICAL; Including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. By JOHN ATTFIELD, Ph.D., Prof. of Practical Chemistry to the Pharmaceutical Soc. of Great Britain, etc. Eighth edition, revised by the Author. In one royal 12mo. vol. of 700 pp, with illust. Cloth, $2 50; leather, $3.

DUNGLISON'S MEDICAL DICTIONARY—Just Issued.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE: Containing a concise explanation of the various subjects and terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence and Dentistry, Notices of Climate and of Mineral Waters; Formulæ for Officinal, Empirical and Dietetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonymes, so as to constitute a French as well as English Medical Lexicon. By ROBLEY DUNGLISON, M.D., late Prof. of Institutes of Medicine in Jefferson Medical College, Philadelphia. A new edition, thoroughly revised and very greatly modified and augmented. By RICHARD J. DUNGLISON, M.D. In one very large and handsome royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, $7 50; half Russia, $8.

CARPENTER'S PHYSIOLOGY—Just Issued.

THE PRINCIPLES OF HUMAN PHYSIOLOGY. By WILLIAM B. CARPENTER, M.D., F.R.S., F.G.S., F.L.S., Registrar to the Univ. of London. Edited by HENRY POWER, M.B. Lond., F.R.C.S., Examiner in Natural Sciences, Univ. of Oxford. A new Am., from the Eighth revised Eng. Ed., with Notes and Additions, by FRANCIS G. SMITH, M.D., Prof of Institutes of Med. in the Univ. of Penna., etc. In one large octavo vol. of 1083 pages, with two plates and 373 engravings. Cloth, $5 50; leather, $6 50; half Russia, $7.

NETTLESHIP ON THE EYE—Just Ready.

MANUAL OF OPHTHALMIC MEDICINE. By EDWARD NETTLESHIP, F.R.C.S., Ophthalmic Surgeon, and Lecturer on Ophthalmic Surgery at St. Thomas's Hospital, London. In one neat royal 12mo. volume of over 350 pages, with 89 illustrations. Cloth, $2.

FLINT'S CLINICAL MEDICINE—Now Ready.

CLINICAL MEDICINE: A Systematic Treatise on the Diagnosis and Treatment of Diseases. Designed for Students and Practitioners of Medicine. By AUSTIN FLINT, M.D., Prof. of the Principles and Practice of Clin. Med. in Bellevue Hospital College, New York. In one large octavo vol. of 795 pages. Cloth, $4 50; leather, $5 50; half Russia, $6.

GROSS ON THE URINARY ORGANS—Lately Issued.

A PRACTICAL TREATISE ON THE DISEASES, INJURIES AND MALFORMATIONS of the Urinary Bladder, the Prostate Gland and the Urethra. By SAMUEL D. GROSS, M.D., Prof. of Surgery in the Jefferson Medical College of Philadelphia. Third edition, thoroughly revised and condensed by SAMUEL W. GROSS, M.D., Surgeon to the Philadelphia Hospital. In one handsome 8vo. volume of 574 pages, with 170 illustrations. Cloth, $4 50.

HABERSHON ON THE ALIMENTARY CANAL—New Edition—Now Ready.

ON THE DISEASES OF THE ABDOMEN, COMPRISING THOSE OF THE STOMACH, and other parts of the Alimentary Canal, Œsophagus, Cæcum, Intestines, and Peritoneum. By S. O. HABERSHON, M.D., Senior Phys. to, and late Lect. on the Principles and Practice of Med. at, Guy's Hosp., etc. Second American, from the Third enlarged and revised English ed. In one handsome octavo volume of over 500 pp. With illust. Cloth, $3 50.

MORRIS ON SKIN DISEASES—Just Ready.

SKIN DISEASES; INCLUDING THEIR DEFINITION, SYMPTOMS, DIAGNOSIS, PROGNOSIS, MORBID ANATOMY AND TREATMENT. A Manual for Students and Practitioners. By MALCOLM MORRIS, M.D., Joint Lect. on Dermatology in St. Mary's Hosp. Med. School. In one 12mo. volume of over 300 pages, with illustrations. Cloth, $1 75.

PARRISH'S PHARMACY—Lately Issued.

A TREATISE ON PHARMACY. Designed as a Text-book for the Student, and as a Guide for the Physician and Pharmaceutist; with many Formulæ and Prescriptions. By EDWARD PARRISH, late Professor of Materia Medica in the Philadelphia College of Pharmacy. Fourth edition, thoroughly revised by THOMAS S. WIEGAND. In one handsome octavo volume of 977 pages, with 280 illustrations. Cloth, $5 50; leather, $6 50; half Russia, $7.

HENRY C. LEA'S SON & CO.—Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing its sixty-first year, the publishers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "THE MEDICAL NEWS AND ABSTRACT," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of FIVE DOLLARS *per annum*.

The "NEWS AND ABSTRACT" consists of sixty-four pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, contributed by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "MONTHLY ABSTRACT," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "NEWS AND ABSTRACT" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum),	Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance,	Five Dollars.
The MEDICAL NEWS AND ABSTRACT, invariably in advance,	Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

HENRY C. LEA'S SON & CO.,
Nos. 706 and 708 SANSOM STREET,
PHILADELPHIA, PA.

Entered at the Post-Office at Philadelphia as Second-class matter.

VOL. XXXIX. No. 2. FEBRUARY, 1881. WHOLE No. 458.

THE

MEDICAL NEWS

AND

ABSTRACT.

EDITED BY

I. MINIS HAYS, A.M., M.D.

PHILADELPHIA:

HENRY C. LEA'S SON & CO.

1881.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.

Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

Entered according to the Act of Congress, in the year 1881, by HENRY C. LEA'S SON & Co., in the Office of the Librarian of Congress. All rights reserved.

NEW MEDICAL BOOKS.

MITCHELL'S CLINICAL LECTURES—Shortly.

CLINICAL LECTURES ON THE NERVOUS DISEASES OF WOMEN. By S. Weir Mitchell, M. D., Physician to the Orthopædic Hospital and Infirmary for Diseases of the Nervous System, etc. etc. In one very handsome 12mo. volume.

BARTHOLOW ON ELECTRICITY—Shortly.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATIONS TO MEDICINE. By Roberts Bartholow, A.M., M.D., LL.D., Professor of Materia Medica and General Therapeutics in the Jefferson Medical College of Philadelphia. In one very handsome 12mo. volume of about 450 pages, with illustrations.

The constantly increasing therapeutic use of electricity, and the absence of a concise guide suited to the wants of the general practitioner, have induced the author to prepare the present volume. His object has been to present the most advanced state of existing knowledge in a form divested of unnecessary technicalities, keeping constantly in view the practical needs of the student and physician.

As the volume is founded upon a course of lectures delivered in the Jefferson Medical College during 1880, its adaptation to its purpose is insured. Dr. Bartholow's power of lucid exposition is well known, and is particularly desirable in a subject such as this, treated from the standpoint of the general practitioner and not of the specialist.

RICHARDSON'S PREVENTIVE MEDICINE—Shortly.

PREVENTIVE MEDICINE. By Benjamin Richardson, M.D., F.R.S., M.A., LL.D., F.S.A., Fellow of the Royal College of Physicians, London. In one octavo volume of about 500 pages.

The immense strides taken by medical science during the last quarter of a century have had no more conspicuous field of progress than the causation of disease. Not only has this led to marked advance in therapeutics, but it has given rise to a virtually new department of medicine—the prevention of disease—more important, perhaps, in its ultimate results than even the investigation of curative processes. Yet thus far there has been no attempt to gather into a systematic and intelligible shape the accumulation of knowledge acquired on this most interesting subject. Fortunately, the task has been at last undertaken by a writer who of all others is perhaps best qualified for its performance, and the result of his labors can hardly fail to mark an epoch in the history of medical science. The plan adopted for the execution of this novel design can best be explained in his own words:—

"With the object here expressed I write this volume. I have nothing to say in it that has any relation to the cure of disease, but I base it nevertheless on the curative side of medical learning. In other words, I trace the diseases from their actual representation as they exist before us, in their natural progress after their birth, as far as I am able, back to their origins, and try to seek the conditions out of which they spring. Thereupon I endeavor farther to analyze those conditions, to see how far they are removable and how far they are avoidable."

ALLEN'S ANATOMY—In Press.

A SYSTEM OF HUMAN ANATOMY: including its Medical and Surgical Relations. For the use of Students and Practitioners of Medicine. By Harrison Allen, M.D., Prof. of Comparative Anatomy and Physiology in the Univ. of Pa. With an introductory chapter on Histology, by E. O. Shakespeare, M.D., Ophthalmologist to the Philadelphia Hospital. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text.

FLINT'S PRACTICE—New Edition—Just Ready.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; Designed for the Use of Students and Practitioners of Medicine. By Austin Flint, M.D., Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y. Fifth edition, thoroughly revised and much improved. In one large and closely printed octavo volume of 1153 pages. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7.

EXTRACT FROM THE AUTHOR'S PREFACE.

In preparing the fifth edition of this treatise, the author has been thoroughly mindful of the progress of medicine since the publication of the fourth edition, in 1873. Time and labor have not been spared in the endeavor to bring the work, in all respects, up to the present state of medical knowledge.

Dr. William H. Welch, lecturer on Pathological Histology in the Bellevue Hospital Medical College, has contributed in Part I. the first seven chapters, embracing the general pathology of the solid tissues and of the blood. He has also revised, and in great part, rewritten the descriptions of the anatomical characters of the diseases considered in the rest of the volume. It is believed that these portions of the work will serve as a digest of the essential facts pertaining to general and special pathological anatomy, as far as this important branch of study bears upon practical medicine.

In the other portions of the treatise many changes will be found, which have somewhat enlarged the size of the volume, in spite of the omission of a considerable amount of matter, and the rewriting of many portions with a special view to condensation. Among these changes may be mentioned numerous improvements in the arrangement, including the classification of the diseases of the nervous system on an anatomical, in place of a symptomatic basis, and the consideration of various diseases not embraced in previous editions. In short, the eliminations, substitutions, and additions render the present edition virtually a new work.

In making changes, the author has not been influenced by a sense of obligation to maintain consistency of views with the previous editions of this treatise, or with other works which he has written. If statements be found to vary from those made at a prior date, the simple explanation is that the latter, in the light of more recent reflection and enlarged knowledge, seem to him no longer tenable. He has endeavored to regard his own past writings, in this point of view, divested of the partiality of authorship, and to subject them to as critical an examination as if they were the writings of another.

Clinical Lectures.

ON THE TREATMENT OF CLUB-FOOT. PARTICULARLY THE CONGENITAL FORM.

DELIVERED DECEMBER 18, 1880, AT THE PENNSYLVANIA HOSPITAL.

BY THOMAS G. MORTON, M.D.,

SURGEON TO PENNSYLVANIA HOSPITAL, FELLOW OF THE ACADEMY OF SURGERY, ETC.

[Reported by Frank Woodbury, M.D.]

GENTLEMEN: Several cases of club-foot, which happen to be in the hospital now, afford me a good opportunity of bringing before you the subject of the treatment of this deformity; and I will therefore devote a part of my hour to the discussion of this topic, and in my remarks I will give you my reasons for expressing views which are somewhat different from those generally held.

In my experience, this deformity is met with quite as often in the female as in the male, or nearly so. Club-foot may be found at birth, or it may result in after-life from injury or paralysis of a muscle or group of muscles; thus, the affection may be congenital, or it may be acquired. Thus, of 46 cases of club-foot which came under my care this year, 21 were congenital, and 25 were acquired. It will simplify the subject under consideration if I briefly point out to you at once the varieties of club-foot and their relative frequency. There are four principal deformities known as talipes or club-foot; and as many secondary forms: thus we have Talipes Equinus, Calcaneus, Varus, and Valgus. These typical forms may be combined or associated so as to form T. Equino-Varus, Equino-Valgus, Calcaneo-Varus or -Valgus. I will illustrate these abnormal conditions upon the foot of our patient upon the table. When the heel is drawn up so that the subject walks upon the phalanges and ends of the metatarsal bones, we have the condition of *Equinus*; when the toes are elevated and the heel supports the weight of the body we have *Calcaneus*. *Varus* refers to a lateral deviation of the foot inward, the outer edge being that part upon which the patient walks; while *Valgus* denotes a contrary condition, the soles being turned outward. When the heel is drawn up and the patient also walks on the outer side of the foot, there is

represented *talipes equino-varus;* or, if on the inner border, *talipes equino-valgus;* in a similar manner *Calcaneus* may be associated with both forms of lateral deflection making *talipes calcaneo-varus* and *calcaneo-valgus.*

Morbid Anatomy.—All these deformities, considered under the generic term *talipes*, depend upon the contraction of muscles or tendons, or paralysis of antagonizing muscles. Sooner or later the bones of the foot, which are not greatly altered at birth, become much distorted and changed in their mutual relations; the astragalus often being most affected, and it may even be congenitally malformed.

Etiology.—Theories the most contradictory have been advanced in regard to the etiology of congenital club-foot. Accept which view you choose, the fact still remains that the condition is due to *an arrest of development* from some efficient cause, which invariably continues to exert its influence through life, upon the subsequent growth of the limb.

Treatment.—In the treatment of club-foot we should have in mind not only the deformity but the causes which have produced it, and for these reasons we employ manipulation, including massage, galvanism, and stretching, these alone, or combined with the section of tendons, and the application of carefully constructed mechanical appliances.

In considering the treatment of individual cases, it is well to remember that we should not use the knife if it is possible to obtain a ready cure of the deformity without it, and never in congenital club-foot until the child is able at least to walk, *i. e.*, about the end of the first year or so. Nevertheless, it must be acknowledged that we may now and then materially shorten the treatment, occasionally even in children, by the judicious division of a tendon or of the plantar fascia. Each case must be a study in itself; and the surgeon will find his best guide in the conditions attending the individual case. There are certain rules, however, in regard to congenital infantile club-foot which have been laid down by surgical authorities; these I think are so erroneous that it is to this subject that I shall especially direct your attention.

History.—Let me say a word or two in regard to the history of tenotomy. The earliest recorded case of club-foot where operation was performed, was about 1784. Delpech after this performed subcutaneous division of the tendo Achillis, but to Stromeyer of Hanover is generally awarded the credit of successfully introducing, in 1830, subcutaneous tenotomy as it is now generally performed. Since that period a number of surgeons have, from their combined influence and favourable experience, placed tenotomy among the regular operations of modern surgery.

Operation.—In performing tenotomy, we use a small, sharp, and a blunt pointed knife; the former to puncture the skin, the latter to divide the tendon; if the surgeon be a dexterous operator he can continue the operation and divide the tendon with the same instrument; but it is usual to relinquish the pointed blade, substituting the probe-end knife to complete the operation; the knife being passed under the tendon, it is divided from below upwards. Many prefer the probe-end tenotome, especially for the tendo Achillis, on account of the proximity of the posterior tibial artery and the veins. In many cases, when the division of the tendon is effected, the sound of the sudden yielding can readily be heard, and when the foot is then put into a normal position, a gap occurs, making a depression which can be seen and felt between the divided ends of the tendon: before making the section, I need hardly say that the tendon should be

placed on the greatest tension. In the course of a few days the interval of separation between the divided ends becomes filled by exudative material, which subsequently becomes organized and finally becomes converted into tendon; in fact the method of union is the same as in soft tissues or bone. At the expiration of about six weeks the union has become so intimate that if the tendon be tested it would more likely yield elsewhere than at the point of union by the adventitious tissue. This early and firm repair in the divided tendon has an important bearing upon the question of the after-treatment, as to the immediate rectification of the deformed foot; thus, shall a club-foot be allowed to remain in its original position, as some advise, for some days after the operation, before an attempt is made by gradual stretching to correct the deformity? I would lay down the rule, that, in all cases without exception immediately after tenotomy, the foot should be restored as nearly as possible to its normal position. The plastic material encompassing the cut tendon bridges the space between the two ends, in the course of a few weeks any excess of new material is absorbed and carried away just as in the provisional callus of bone, and thus the tendon is left permanently lengthened as desired. This is, therefore, an important point, not to permit the deformity to continue after tenotomy, but to reduce it by manipulation and stretching, while the patient is still under the influence of the anæsthetic. The operation of tenotomy is an easy one, requiring but ordinary care and little skill, although I have known of more than one fatal result following from erysipelas, and sloughing, and hemorrhage in this apparently trifling subcutaneous operation. The after-treatment, however, requires attention and careful management to prevent a recurrence of the deformity; should the latter occur, it would have been far better if no operation had been performed, for subsequent surgical treatment is much less satisfactory than if the case had been left quite alone.

Age for Operating.—There is another very important point: How early should you divide tendons in the treatment of club-foot? The very first case you may have to treat in your practice may be one of congenital club-foot. You turn to the authorities to learn the time for operating, and you find that Holmes in his "System of Surgery" says, that, "If at the expiration of the fourth week distinct contraction of the tendons remains in spite of assiduous efforts to overcome the deformity by manipulations, frictions, and steady but gentle employment of splint and bandage, or if benefit proportionate to the attention bestowed be not realized, or if the case unequivocally belongs to the second or third degrees of varus, the aid of tenotomy will be required to effect restoration."

Gross[1] says: "When the distortion is considerable I invariably employ the knife as a preliminary measure, and this may always be done with the most perfect safety even within the first four or five weeks."

Ashhurst,[2] in speaking of tenotomy, says: "In cases of ordinary severity tenotomy should be resorted to, the best age for the operation probably being between the second and third months of life." With the views just expressed, though with sincere respect for these authors, I cannot agree, and I shall presently give you my reasons, and at the same time show you in support of my views the practical results of another kind of treatment.

In discussing the varieties of congenital club-foot we will find that seve-

[1] System of Surgery, 5th ed., Phil. 1872, vol. ii. p. 1047.
[2] Principles and Practice of Surgery, p. 634, 1878.

ral can be readily disposed of, after which I shall devote my remarks particularly to the deformities which require the greatest care and attention on the part of the surgeon to insure complete success.

Talipes equinus is caused by the shortening of the common tendon of the gastrocnemius and soleus muscles, the tendo Achillis. It is seldom that this deformity if marked can be cured by any other means than the division of the tendon, yet I advise you never to operate until the child can stand or walk, then you get the best result possible, for in the joint motion the tendon and muscle are constantly stretched, which is not the case if the tendon is cut during infancy when the heel surely will become elevated. The tendo Achillis is divided just above its insertion, the heel is at once brought down by force if required, and the foot is held down by the band across the instep which is attached to the usual apparatus. In many cases of acquired club-foot there is not only a weak condition of the ankle, but it is well to bear in mind that more or less atrophy of the bones and muscles exists; in congenital club-foot this atrophy also exists, so that a brace affords the necessary lateral support not only to the ankle but for the entire limb. It is all-important to have the heel in good position, and this is done by pressing the foot well down in the shoe while lacing it up, then carrying over the strap before alluded to across the instep. The instrument consists essentially in a padded and well-fitting shoe, fastened in a steel frame, which has two bars running on the inner and outer side of the leg up to the thigh (in some cases only to the knee) united by a transverse bar below the shoe, having hinges opposite the knee and ankle-joints, and bands above and below the knee. (See Fig. 1.)

Fig. 1.

Talipes Calcaneus, a rare form of congenital club-foot, generally acquired as a result of infantile palsy, requires division of the tendons of the tibialis anticus, the common extensors, long extensor of the great toe, and the third peroneal (peroneus tertius) muscles. The apparatus required is the same as that for equinus just described.

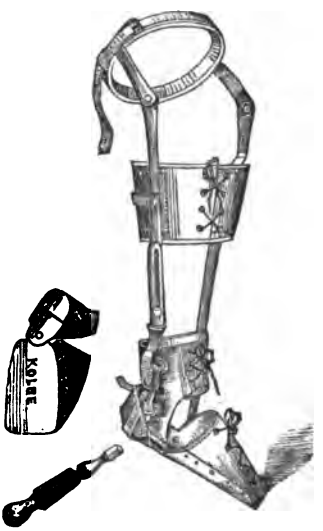
Talipes Valgus (or splay-foot) is common as an acquired affection and occasionally requires division of the peroneus longus and brevis, and sometimes, the tibialis anticus and tendo Achillis; such cases also need the same form of apparatus as described for equinus and calcaneus to keep the foot in good position, and forcible stretching is often required before the apparatus is applied.

Talipes Varus, the most frequent and important of the club-foot deformities, is generally associated with a greater or less degree of elevation of the heel, forming that variety known as talipes equino-varus. I lay more stress upon this form because probably more than ninety per cent. of all congenital cases belong to some form of varus, and because its treatment is often most wretchedly mismanaged; of the twenty-one cases of congenital club-foot which I have already referred to, all were examples either of varus or equino-varus.

Varus and equino-varus, if examined soon after birth, will show more

mobility of the tarsal articulation and foot pliability than you might be led to expect. The muscles at fault in varus are usually only the anterior and posterior tibials, and in equino-varus in addition to those named the tendo Achillis. But in most cases of varus you will find all the structures including the bones very susceptible to manipulation, so that the tarsal arch with all the other parts associated in the deformity may be pressed and stretched into a normal position. *All* cases of congenital varus and many cases of equino-varus can be cured by persistent stretching without any operation; therefore in these cases it is necessary that the treatment should commence at birth, and the nurse or attendant of the infant should be instructed how to daily manipulate the foot. I now show you an infant with double equino-varus, and, asking the mother to perform this simple operation before you as she is accustomed to do it, you observe that pressing in the prominent tarsus with the thumb, the rest of the mother's hand securely grasps the foot at the inner side, and by a steady outward movement and partial rotation the foot is at once brought into a normal shape; but it often happens, as in this case, that the equinus can only partially be overcome; this can readily be rectified by cutting the tendo Achillis when the child is ready to walk. It is sometimes well in stubborn cases of varus to keep up for some hours daily a continuous outward stretching, and this can be accomplished by the use of the shoe (see Fig. 2) which by the aid of the ratchet side motion, the foot being well secured, can be thoroughly everted; still this shoe should not be relied upon solely, for the foot of an infant confined in any apparatus necessarily brings about a want of circulation, atrophy, and often excoriations which retard, if not stop temporarily, all treatment.

Fig. 2.



Unless we have the weight of the body upon the foot as in walking, the equinus is likely to return. Even with a shoe, if the child does not walk, it is practically impossible to keep its heel properly down; it will be drawn up, and defeat your object. But if you defer tenotomy of the tendo Achillis until the child is able to walk or until it is two or more years old, if the elevation is not too great, you will on the contrary have the best results. When you have corrected the varus and the child is ready to walk, an apparatus is required to overcome the tendency to a recurrence of the deformity; years ago I commenced using a modification of the ordinary Scarpa's shoe, which simply allows a hinge motion at the ankle but in no wise everts the foot. To give this outward ankle-motion, the apparatus is arranged as follows: Taking an ordinary leather shoe, which should lace up in front, with the lateral steel supports running up above the middle of the thigh, with transverse braces and bands, a hinge is placed opposite the external malleolus, and opposite this point on the inner steel rod a portion has been taken out and replaced by a toggle joint, or double antero-posterior hinge (Fig. 3), which enables it to yield when the child bears its weight

on the inner side of the foot; the hinge on the outer side allows the foot to turn outward (Fig. 4). This I look upon as a valuable addition to the apparatus for children and one well worthy of your attention.

Fig. 3.

Fig. 4.

Case I.—This boy, aged five years, which I now present to you with such admirable feet, so perfect that you would never suspect him to have been a subject of the worst form of equino-varus, was placed under my care shortly after birth with the request from the family physician that I would perform tenotomy; explaining the process of stretching and the value of such persistent efforts to his parents, and with their hearty co-operation; at the end of a year I had the pleasure of seeing the left foot entirely cured both as to the equinus as well as to the varus; in the right foot at the age of three years there was an equinus remaining, so I divided the tendo Achillis, the varus having been entirely cured. When this child was ready to walk, I told the father, Mr. W. P. Thomas, of this city, who has had considerable mechanical experience, that if he could arrange, as he first suggested, such a joint at the inner ankle as would give to the parts an outward motion as the child placed the foot on the ground, I thought it would be of even more service than the daily stretching which the child had been subjected to; he at once constructed the toggle joint which I have just shown to you; this I have been using ever since with excellent results. It has been suggested that the treatment by stretching is very slow, and that much time might be saved by tenotomy. To this I answer that unless even more care is devoted to an infant's foot after tenotomy, than in the simple stretching process, the results will be far from satisfactory, and that a club-foot neglected after operation is far less amenable to treatment than a club-foot that has never been treated at all. It is not well to keep constantly upon a child recovering from club-foot an apparatus after a good position has been obtained. I am in the practice of allowing the child to wear for an hour or two daily a pair of slippers, in order that the ankle-joint shall have all kinds of motions during the child's play; this I look upon as important: and, in regard to the use of mechanical apparatus at night, I am quite convinced that, as it is unwise to use any such apparatus for the infant, so it is unnecessary for the child;

the limb develops better, and a good stretching before the child is put in bed is far better than any apparatus which confines the limb during sleeping hours and retards the circulation and growth.

In considering the unyielding, rigid equino-varus which we often see in after years as the result of want of care after operations, and in those cases in adults where no operation has ever been performed, we find that the section of tendons and fascia, although accomplishing with apparatus considerable, is not by any means sufficient to insure a cure of many deformities, and for years past I have been in the habit of poulticing such stiff, rigid feet for a fortnight or so before operating, in order to thoroughly soften them, and it is wonderful how much is gained by this simple procedure. Then, under an anæsthetic after the division of all the tendons involved in the deformity, I apply either the "foot stretcher" (Fig. 5) which I devised some years ago, or the one gotten up at my suggestion by Kolbé, and with either of these force the unyielding bones at once into as correct a position as possible; and this operation may be repeated as often as may be necessary. The apparatus is simple: it consists of a block of wood on which there is fastened an inverted and well-padded horse-shoe, into which the heel of the foot is secured by straps passed through the slots, over the instep; a pad draws strongly upon the projecting tarsus by means of a powerful screw, another band and screw is connected with the forward part of the foot, and makes traction in the opposite direction; an immense force is thus brought to bear upon the deformity; flexion and rotation of the foot is readily obtained by moving the wooden block. The apparatus is applicable to either foot. The other stretcher is a more powerful apparatus, and can be used upon either foot; a glance at it shows you its applicability (Figs. 6, 7). I have never known any injury result from this method of treatment, and I say to you that without some such apparatus, you will not be able to cope with many of the old deformities to which I have referred.

Fig. 5.

It is in most cases necessary to divide the plantar fascia; this you can readily do by a division of the tense tissue readily felt running lengthwise on the inner and under side of the foot. In illustration, I now show you several other cases bearing on my statements in regard to the plan of treatment of congenital club-foot by stretching or combined with division of the tendo Achillis.

Case II.—This little girl, eight weeks old, was born with bad equino-varus of both feet; by continued daily stretching by the hands of the mother she has very much improved, the varus is readily rectified and the equinus is improved; when the child is ready to walk the tendo Achillis may require section; the parent is directed to continue the manipulations, and to present the child every month or so for inspection.

Case III.—This infant three months old has, on account of a double congenital equino-varus, been subjected to stretching since birth; the positions of the feet are nearly normal, and I think that manipulation alone will

be sufficient. You will notice the excellent position of the tarsus, and my ability to get rid of the equinus with a moderate force.

Fig. 6.

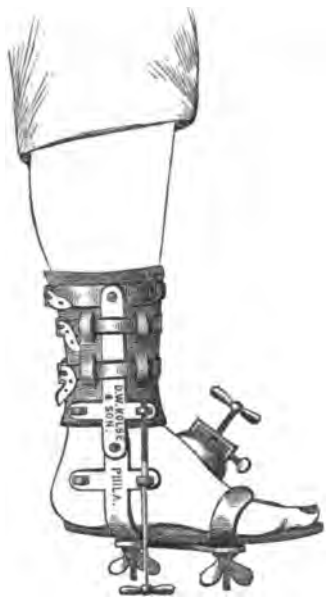


Fig. 7.

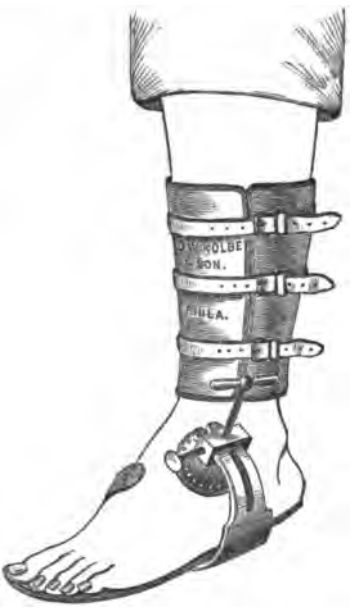

Case IV.—This boy, now seven years of age, was born with double equino-varus, and is a brother of the child last presented to you. He now has perfect feet, and all this has been accomplished without tenotomy, by the lad's mother, and from her success with the boy she is thoroughly satisfied that her efforts with her infant will be successful. He now has no need for any brace, which indeed he has not worn for more than a year.

I need not now adduce any other cases in support of my practice, but may say to you that I have brought a large number of similar instances before the Philadelphia Academy of Surgery during the present year to show the importance of the treatment by stretching.

Cases V. and VI.—Of the two cases I have for operation this morning, the first is this lad Eugene D., aged six years, who was born with equino-varus; when nineteen months old the varus was cured by manipulation, but he subsequently required division of the tendo Achillis for an equinus. He has an excellent foot, with a tendency to varus, which a shoe will not rectify because the plantar fascia is the cause of the inversion. This must be divided, which I now do, the patient being etherized. He shall now wear this shoe (Fig. 8). At its outer edge, an elastic band is attached which is connected to the apparatus below the knee. This draws the foot upward with each step, and tends to evert it at the same time. I have spoken to you of neglected club-foot, and here you have an example. This girl, of seventeen years of age, has congenital equino-varus; she was admitted into the hospital, Dec. 13th, with an exceedingly rigid foot. She has walked so long on the outer side of the foot that the tissues from the constant pressure are very dense. The heel is also

drawn up. Now such a case would yield but slight results from a tenotomy operation alone. The foot has been enveloped in a flaxseed poultice day and night for the past week, and the good effect of this course is here shown. The skin and subcutaneous tissues are now very pliable. In order to relieve the equinus, I place the foot on the stretch and divide the tendo Achillis and the separation between the ends of tendon is at least an inch, and I divide the plantar fasciæ, overcome the varus, and, with force, rupture the unyielding tarsal tissues, and at once rectify the malposition.

Fig. 8.

I frequently, especially in adult cases, where much force has to be used, apply for the first week or so a right angle posterior felt (Fig. 9), pasteboard or tin splint; if the latter, there should be a good opening for the heel; the splint should be carefully padded so as to avoid excoriations; after a time the regular walking shoe is substituted.

From the remarks I have made to you this morning, it will be evident that my object has been to discourage tenotomy in infantile life; that talipes equinus, calcaneus, and valgus can be readily and successfully overcome and seldom give rise to difficulties in their treatment; that all cases of congenital varus can be cured without operation if attended to early, and that the equinus, which is so often associated with varus, not infrequently requires division of the tendo Achillis, but that this operation should *never* be done until the child is ready to or has commenced to walk, for at this time you have to aid you in the cure, the constant flexion and extension of the foot, which must necessarily occur with every step. Then the use of the toggle joint, as I have described to you, will overcome the disposition to a recurring varus, which has to be guarded against for a long time. Then again, I have urged the importance of not confining children's feet too long during the day in any apparatus, for club-foot is essentially due to an arrest of development, and our efforts should be to encourage the growth of the limb, by the means already referred to, and that excellent results are observed in a freer ankle motion if the child be allowed to play for an hour or so each day without any apparatus.

Fig. 9.

I have thus briefly given you my experience in the treatment of club-foot, and I am quite sure that if you will give the subject your careful consideration, you will abandon the use of tenotomy, at least in the very early treatment of this deformity, and trust rather to the various methods which I have endeavoured to impress upon you.

LECTURE INTRODUCTORY TO THE STUDY OF THE ARTHRITIC DIATHESIS.

Delivered at the London Hospital.

By JONATHAN HUTCHINSON, F.R.C.S.,
Senior Surgeon to the London Hospital.

It is my purpose, Gentlemen, to bring under your notice the peculiar and very important group of diseases to which our forefathers applied the term arthritic. You are well aware that although this term, used according to strict etymology, means any inflammatory affection of a joint, yet that, conventionally, it has been restricted to certain morbid conditions in which a remarkable tendency is shown for many joints to suffer, and to suffer repeatedly. An arthritic person is one who over and over again suffers from inflammation, more or less transitory, of his joints, and who is so liable to it that he knows what are the influences which are likely to produce an attack. It is thus quite clear that a tendency to arthritis in this sense is a constitutional one. Other diseases of joints may be local, but true specialized arthritis, although often excited by local causes, always has in the background a constitutional peculiarity as its source. To this constitutional peculiarity we give the name of diathesis; and when we say of any one that he is the subject of the arthritic diathesis, we mean that he is in that bodily condition—of that organization—which renders him liable at some time, and under suitable provocations, to become the subject of active arthritic manifestations. It by no means follows that an arthritic man is always, or even often, suffering from arthritic maladies, any more than that the witty man is always brilliant; it is sufficient in each case that the basis qualification, the potentiality, be there. In each it is quite possible that the possessor of such qualification may go through life, and transmit to his successors his possession, without having ever himself exhibited it in an unmistakable form. Now, although liability to joint inflammation is the feature which gives its name to the arthritic diathesis, I must warn you against the notion that it is the only phase by which that diathesis manifests itself. It would be strange, indeed, if such were the case, and if it were possible that a constitutional state could exist which should give proclivity to inflammation of the joints, and should exempt wholly the other tissues. Although the joints suffer chiefly, and present the most prominent symptoms by which we recognize the diathesis, yet they take simply the first rank, and by no means an exclusive one. There is no structure in the body that may not be attacked. We have, possibly, arthritic dyspepsia, arthritic renal disease, arthritic pneumonia and bronchitis, arthritic affections of the skin; it is certain that we have many arthritic affections of the fascia, muscles, nerves, and eye. Hence, in part, arises the great importance of the subject to which I invite your attention.

Here we may suitably pause to assert that arthritic inflammations, whether strictly arthritic in the sense of attacking joints or otherwise, have a peculiarity of type. This peculiarity is such that by it alone their true nature may often be guessed in cases where other points of evidence are defective. They are, as a rule, remarkable for suddenness of onset, rapidity of development, and certainty of decline. If, however, there is a strong tendency to spontaneous decline, there is also one equally strong to future recurrence. There is about them all a here-this-week,-gone-the-next,-certain-to-come-again-some-time quality, which is most characteristic. As a rule, they are all, when at height, attended by very severe pain, and relatively to the intensity of the inflammation there is but little

tendency to disorganize. Above all, in strong contrast with other inflammations, they show no tendency to cause suppuration. Lymph effusions there may be, and adhesions may result, slow alterations in the forms of bones and in the texture of ligament and cartilage may take place, but these are unusually trivial in proportion to the apparent intensity of the inflammation. It is a matter of astonishment to every one who watches these cases how surprisingly good reparation is when the attack passes off. In many cases it is not perfect, but in almost all it surpasses the expectations formed even by well-skilled spectators. I leave aside for the present certain forms of what are called arthritis, in which the malady appears to persist, and to produce, by slow, uninterrupted processes, great ultimate disorganization. These are very exceptional as to number, and far less so as to character, than they have been supposed, and they by no means invalidate the general statement that arthritic maladies are, as a rule, paroxysmal in character and remarkable for the excellence of the recovery which follows. If you hear of a man having had repeated and violent attacks of pneumonia, from each of which he has recovered perfectly; if of another that he is laid up every spring with severe iritis, yet every summer appears to see nearly as well as before; if of a third that he is frequently the subject of joint inflammations, whilst yet he never becomes disabled, you may in each case make a safe guess that the malady in question was of the arthritic type. The knowledge of this tendency to spontaneous recovery is of the utmost use to us in prognosis.

I have been hitherto speaking of the arthritic diathesis as if its existence were acknowledged by all nosologists, and it is time that I should admit that this is in the present day by no means the case. The term is a decidedly old-fashioned one, and if I venture to ask you to employ it, the duty devolves upon me of defending it and of showing that it is one based upon clinical fact. In the present day we are taught to speak of gout and rheumatism as essentially different maladies, yet both come into the old category of arthritis. Respecting rheumatic gout and the various forms recognized under the name of chronic rheumatism, although there is much difference of opinion and many contradictory statements extant, yet I believe I am right in stating that the balance of authority is in favour of the belief that they stand distinct, both from gout on the one hand, and acute rheumatism on the other.

Let me here attempt a brief glance at the kind of facts with which in the following lectures we shall have to deal, and at the terms by which they may most appropriately be designated. Let me also beg of each one of you to be most careful in defining his terms, for there will be no hope of our getting to the bottom of a complex question like the present one unless we are studious, on the one hand, to get clear and vivid conceptions of facts, and on the other, to use words in reference to them which we all employ in the same sense.

The time-honoured name of "gout" is one which is well understood, and of which the equivalent has been used from the days of the Romans, with singularly little difference of opinion as to the cases to which it is applicable. If the case be well characterized every one can recognize gout, for its symptoms are most definite, and almost every one, lay as well as medical, knows what they are. All that we have said as to the peculiarities of arthritic maladies finds a most definite realization in the case of gout. It is paroxysmal with a vengeance, and in it suddenness of onset and of decline, persistency of liability, and comparative freedom from local disorganization, find emphatic illustration. To these general characters we may add that gout usually attacks the smaller joints first, giving, indeed, primal preference to that of the great toe, that its acme is marked by great swelling of the parts external to the joint, by a glossy skin, which pits on pressure, and which desquamates when the attack is past, by the most intense

pain, and by great disturbance of health, more especially of the nervous system. Modern pathological research has given increased prominence to another symptom long well known. I allude to the secretion of chalk, or of a substance which looks like chalk. This salt, the white lithate of soda, is formed so constantly in gout that its presence or absence may, I think, be taken as the line of demarcation between true gout and rheumatic gout. Unfortunately, it is only in the latter stages of the malady that the presence of this salt can be proved during the lifetime of the individual. In advanced cases of gout we may find concretions about the affected joints or in various other parts, more especially in the cartilages of the ears. The researches of Dr. Garrod would tend to show that the examination of the blood during the paroxysm, and the detection of lithic acid in excess in that fluid, is always a pathognomonic and reliable symptom. It is unfortunately, however, one difficult of application, and in a majority of cases not available. The valuable researches referred to, supported as they are by a multitude of pathological data previously and since recorded, have, however, enabled us to place this symptom in the foremost rank in reference to the diagnosis. I believe I am giving you a definition which all will accept when I say that we count as gouty all manifestations which occur in connection with a state of health in which lithic acid is present in excess in the blood, and in which there is a tendency to the deposit of its salts in the tissues. You will note that we by no means require absolute proof of the presence of lithate of soda at any given time, or in any given case. If you have succeeded in making yourself and others believe that certain symptoms are essentially connected with a state of health which usually has for its result the excessive production and depositing of this salt, then you have succeeded in convincing yourself that those symptoms are in essential nature gouty. Perhaps not in one case in twenty in which we diagnose gout do we prove lithate of soda, but we ground our opinion upon the close resemblance of the symptoms to those in other cases in which lithates were demonstrably present. And mark again, I by no means join with those who regard the presence of lithate of soda as the true beginning of gout, or even as an essential phenomenon. It is only one of many concomitant results of a special state of the system—special as regards inherited organization, as regards digestion, assimilation, and excretion—but it is one so definite and so frequently present that it may be very suitably selected as the characteristic on which to base a conventional name. I have already implied, and shall assert more explicitly soon, that I regard the attempt to separate rheumatic gout from true gout by an abrupt line as a violence to sound pathological doctrine. It is very desirable, further, that you should not narrow your conceptions of the meaning of this important word. It is incorrect to say of any man "he has got the gout," in the same sense that we should say "he has got syphilis," "he has caught the measles." There does not exist any such abstraction as "the gout," or perhaps I ought to say there is no such entity. A man may *become gouty*—that is, his assimilation may have been slowly changed, and all his tissues modified in character, so that they may be liable to inflammations of the gouty type—but he cannot receive into his system *de novo* the malady "gout," for the simple reason that no such entity exists. I repeat that a clear conception on this point is essential, for unless you have it you will never make due allowance for the modifications which the gouty diathesis is so prone to undergo. It is precisely because it has been built up as the slow result of numerous complicated and prolonged influences that no two cases are precisely alike, that although the well-marked examples of it are very peculiar and utterly beyond all dispute, there are others, the recognition of which will task to the utmost the skill and insight of the physician. Nothing is easier in the cases I refer to than for equally well-informed and candid observers to become involved in an inter-

minable war of words. Recollect, then, that our definition of gout is a conventional one, and that it applies to the better-marked states of system which are susceptible of the most multifarious complications and of endless modifications in degree. Thus it is quite fair, quite consistent with probable truth, to say of any given case, This is not gout, but it is closely allied to it—a phrase which, in the instance of a syphilitic malady, would be simply nonsense.

Having thus attempted to define the class of maladies which we may properly call gouty, we will now turn to the subject of chronic rheumatism or rheumatic gout. This malady, like true gout, has long been recognized, and many have been the debates as to what name it ought to receive. It presents even greater varieties as to form and severity than gout itself, and hence many discrepancies in authors respecting it. We will again endeavour to take pathological results as the basis of our definition. The results of rheumatic gout to the joints affected are very peculiar. There is no deposit of lithates, but there is a change in all the textures of which the joint is composed. The synovial membrane thickens, and its fringes become developed, from which pedunculated or loose cartilages at length result. The ligaments soften and stretch, and the cartilage becomes fibrous and splits up or wears away. But whilst these changes are going on in the soft parts, yet more characteristic and permanent ones are happening in the ends of the bones themselves. These, in mild cases, have rows of little nodosities developed on the line of junction between periosteum and cartilage, whilst in more severe ones these nodosities become confluent, and constitute projecting lips, often of very considerable size. In the worst cases all the ends of the bones alter remarkably in form, and become expanded to twice their original size. In some cases there is great expansion, with but little evidence of wearing away; in others the bone eburnates instead of expanding, and retains its form, but becomes polished and fluted by friction. In aggravated cases great crippling and great deformity is the result, and hence one of the names by which this disease is known on the Continent—*arthritis deformans*. But here let me raise protest that it is not every case of rheumatic gout which is deforming—not the majority, rather a small minority, and those chiefly in patients who are elderly. Rheumatic gout is a very common malady, far more common than true gout, and if, before we pronounce on its existence, we wait for the manifestation of visible deformity, we shall miss the diagnosis of all the milder cases. I have often taken occasion in this theatre to warn you against the too common mistake of selecting for study and for record only the most exaggerated and intense forms of a malady. Endless are the misconceptions which have resulted from this error, and few subjects have suffered more from it than the one under consideration. If every subject of the gouty diathesis would be kind enough to carry about specks of chalk in his ears, the recognition of gout would be easy enough; and in like manner we could easily tell rheumatic gout if all its subjects had their limbs crippled and deformed. But it is not so, and in each instance we are, in a majority of cases, thrown upon our ingenuity for the discovery of other and less obvious guides to the knowledge of our patient's real state.

Of the peculiarities presented by joints which have suffered from rheumatic gout, two stand out before all others in their value as means of diagnosis—I allude to the dry grating caused by the removal of cartilage, and the development of lips. We may venture to assign the chief place to the second of these, for it is the one which is earliest to be found. Grating is never present excepting at an advanced stage, and although very characteristic then, its value becomes, of course, much limited by that fact. Nodosities and lips, on the contrary, are amongst the very earliest of the products of this malady, and are often, indeed, present before the patient is aware that he has had any inflammation in the joint

concerned. Nor have we, so far as I know, any reason to think that they occur to any characteristic extent in association with any other causes.[1] On the contrary, I believe that their diagnostic value is as great in rheumatic gout as is that of chalk concretions in true gout. Our differential definition of rheumatic gout may then, I think, be based on these peculiarities, and we may say that any form of joint disease which tends to the production of lip-like outgrowths at the margins of the cartilages has a claim to be placed in this category. I have already hinted that there are many varieties, some of them probably of considerable clinical importance, which are grouped under this head, and that in a certain large group, occurring in patients under middle age, whilst removal of cartilage is common, outgrowths of bone are rare, and if present usually small.

For the last few years I have been in the habit of using these outgrowths for the purpose of diagnosis in a somewhat novel way. I had often been struck by the remarkable prominence of these rheumatic lips on the condyles of the femur in museum specimens, and it occurred to me that they ought to be perceptible during life. I examined the knees of a few patients who had the disease in an advanced stage, and found that I could detect them very easily. Afterwards, with some practice, I found that I could appreciate their presence even in comparatively early stages, and also that they are frequently present when the patient has no external deformity whatever. By degrees, and after the examination and comparison of a great number of patients, I have come to rely with much confidence on this symptom. If you wish to employ it successfully, you must first practise carefully on healthy joints. In many, if not in most, there is a ridge at the part referred to, more or less resembling the pathological lip. The distinction between health and disease can only be acquired by practice. In examining a knee, I prefer to place myself in front of my patient, and to employ both hands at once. I place the finger-tips of one hand flatly over the edges of the one condyle, and those of the other on the opposite, and then direct him to bend and extend the joint slowly several times in succession. In this way you may find the edges and appreciate their elevation without risk of error. I much prefer to use the fingers flatly at first, and not to employ their tips, as I think there is less risk of error in estimating elevation; but afterwards I use the tips in order to determine whether the lip overhangs. In well-marked cases it curls outwards.

These condyloid crests, as I have already observed, are not to be expected in all cases. As a general rule they are present only in those who have passed middle life. You must not expect to find them in the young. In the latter, absorption of cartilage without osseous outgrowth is the rule. In the aged, however, these crests are invaluable as symptoms. I have very often recognized them in cases in which the patients were not aware that the knees had ever suffered. I have often been able by their aid to say which knee had suffered most frequently, and have found the patient's statement confirm my inference. The symptom is of especial use in those cases in which we are consulted, not on account of joint affections, but for iritis, or lumbago, or a skin disease which we suspect to be of arthritic origin.

I have hitherto said little or nothing as to clinical peculiarities of rheumatic gout, beyond a hint that they are by no means the same in all cases. I intend in a subsequent lecture to consider them in detail, but for my present purpose I

[1] I have just seen a case somewhat exceptional to this statement. A young woman under the care of my colleague, Mr. McCarthy, had her limb amputated on account of a myeloid tumour in the tibia. She had never been rheumatic, but there were present small lips on the edges of the condyles. No doubt the joint-changes had been induced by the proximity of the tumour.

must here give a short sketch in order to contrast them with those of gout. In many cases rheumatic gout begins insidiously, the patient being simply liable to attacks of aching in one or more joints. It affects large and small joints almost indiscriminately. It is remarkably prone to produce synovial effusion. Almost all cases of so-called hydrops articuli belong to it. Unlike gout, and unlike acute rheumatism, it but rarely causes redness of the skin, and the shiny surface and œdematous pitting are scarcely ever present. Its paroxysms are often prolonged or of indefinite duration, but in some cases, contrary to the general belief, I must assert that they are as short and definite as those of gout itself. In other cases —and these are those more nearly allied to rheumatism than to gout—the first attack sets in severely and affects many joints. In these, instead of getting well at the end of a month or five weeks, as acute rheumatism is in duty bound to do, the disease lapses into a chronic form, and the patient may perhaps become an invalid for the remainder of his life. Still, even in these persistent cases there are generally observed remissions and paroxysmal recurrences. The pain which attends rheumatic arthritis never rises to that extreme severity which characterizes gout, but it is often bad enough.

Rheumatic gout presents great difficulties as to diagnosis in two different directions: there are cases which the physician can scarcely tell from acute rheumatism; there are others, and very different ones, which it is almost impossible to distinguish from true gout. My own belief is that in each of these instances the difficulties are insuperable, for the simple reason that the maladies in question do really merge into each other, and that the features characteristic of each exist in union.

On the third great subdivision of the arthritic family I shall not now speak. It is that of rheumatic fever or acute rheumatism.

Here then, gentlemen, to recapitulate, we have glanced at the three large subdivisions of the arthritic family; we have seen that gout is peculiar in having deposits of lithate of soda, rheumatic gout in having in the young ulceration of cartilage, and in the old absorption of cartilage with outgrowths of bone, and acute rheumatism in having synovitis without permanent articular changes, and in being very prone to damage the heart. Our next question is, Are these three maladies really related or not, and if so, to what do they owe their individual peculiarities? Let me insist that it is a question of relationship merely, not of identity. No one denies that there are most important differences between the three—differences which it is wise and convenient to recognize by distinctive names. Still, however, the question of relationship remains a most important one. I may here conveniently admit to you, as, indeed, I have perhaps already done, that all three depend upon the same diathesis or constitutional state, and that their differences are due to the varying conditions as regards age, sex, temperament, habits of diet, exposure to climate, etc., to which the possessors of this diathesis are exposed. You will easily, I think, see that it is of great practical importance to answer this question correctly. If relationship be admitted, there is little doubt that our opinions as to the treatment of each will receive some modification. It is not, however, as regards the principles of treatment that most is to be anticipated, for the differences between the three when in actual existence are quite sufficient, however they may have been acquired, to make it probable that great differences in treatment will be necessary. As regards prevention, as regards the general management of health in those in whom the diathesis is as yet latent, or in those who are known to be descended from arthritic subjects, much more may be expected. Very probably we may find that the same general measures which prevent the one will also ward off attacks of the other. There are also other important and common maladies respecting which

our notions will be much cleared if we can decide whether there does or does not really exist an arthritic diathesis which is the common parent of gout, rheumatism, and their allies. I allude to such maladies as brow-ague, lumbago, sciatica, recurrent iritis, gonorrhœal rheumatism, and certain skin diseases. In trying to ascertain whether any one of these is really dependent upon an arthritic diathesis, we are at once met with the difficulty—What constitutes proof of that diathesis? If one patient with recurrent iritis tells me that his mother was crippled with "rheumatic gout," but never had "gout," and another that his grandfather was a martyr to "chalk-stone gout," how am I to interpret the facts? Am I to say that the two histories, referring to totally distinct maladies, help me not at all to an explanation of iritis, or am I entitled to assume that in both the facts imply the existence in the family of the arthritic tendency? Such questions meet us every day in practice, and the advice which we give our patients is based upon the opinions respecting them which we chance to hold. I need say no more to enforce upon you the importance of the investigation which I propose to commence.

We must next ask, How shall such a question be set at rest? On what data can we determine the relationship or non-relationship of any given maladies? On this point I must confess I have not been able to find much information in the works which I have consulted. Although the question has been much debated and with great ability, yet I cannot help thinking that it has never been stated with sufficient precision. The proofs of relationship between any two given diseases must be of the same character as those by which we should prove alliance of any species in animals, and first among them stands, Are they the offspring of a common parentage? First cousins or even brothers may be of very different aspect; but prove their descent, and you prove their relationship. In respect to gout and rheumatic gout, it appears to me that physicians have been far too much concerned with the examination of differences, and have almost forgotton to ask, Are they not producible by the same causes and influenced by the same circumstances? I fully admit that the investigation of the cause of these maladies is surrounded with difficulties, but nevertheless much has been, and much more may yet be, effected, not only by the critical investigation of individual patients, but by ascertaining whether any given races, or any given climates or occupations, are particularly prone to produce them. If, for example, it be found that gout and rheumatic gout prevail in excess always in company, —that the same race, the same climate, the same sex, and similar ranks in society, are liable to both,—the inference as to identity of cause would become strong. Then, again, we have data of great value derivable from the history of hereditary transmission. If I succeed in making it probable that gout and rheumatic gout prevail in the same families, and that of the children of a gouty father some suffer from rheumatism and others from true gout, I feel sure that your inference from the fact will be that it is probable that the diathesis is the same, and that it derives its peculiarities in each instance from some other special conditions in each sufferer—sex, temperament, etc.

Thirdly, we have the test of hybridism. Is it possible to mix up gout and rheumatic gout together, or rheumatic gout and true rheumatism, so that the characteristic features of the two shall be blended? Of course it is very possible for two quite distinct maladies to prevail by mere chance in the same person at the same time; but if we find that this admixture is common—that it is, in fact, the rule rather than the exception—then, I think, most will agree that such easy blending is strongly in favour of prior relationship.

MONTHLY ABSTRACT.

Anatomy and Physiology.

A Spinal Root of the Optic Nerve.

STILLING, of Strasburg, showed preparations to the International Ophthalmological Congress at Milan, in September last, which he believes demonstrate the existence of a spinal root of the optic nerve, which brings the retina into direct connection with the medulla. This root passes from the external corpus geniculatum, in a winding course, deep between the bundles of the crus cerebri, and can be traced into the pons; and it appears to course down in the direction of the medulla, although its further progress cannot be demonstrated. The existence of this branch is interesting on account of the light it throws on certain physiological relations between the medulla and the retinæ, and may constitute the hitherto undiscovered link between certain diseases of the spinal cord and of the optic nerve.—*Lancet*, Nov. 27, 1880.

The Effect of Exertion on Temperature.

Dr. BONNAL, of Nice, has been experimenting on the effect of muscular exercise on the temperature of the body. The observations were made on four individuals, the temperature being taken in the axilla, popliteal space, groin, foot, hand, mouth, and rectum. The investigation has been prosecuted during four years, and the conclusions reached are the following: All muscular exercise, even if of short duration, raises the temperature of the rectum, rarely, however, to a point exceeding 101° F.; but the rise occurs invariably, at whatever hour the exercise is taken, whether before or after rest, and independently of age, sex, and meteorological conditions. The effect bears no relation in degree to the duration of the exercise, or to the apparent fatigue. The influence of the same exertion, under identical conditions, varies in different individuals, and in the same individual at different times. The physical altitude, the state of the atmosphere, and the amount of clothes, exercise, as might be anticipated, a marked influence on the degree, and especially on the rapidity, of the rectal rise in temperature. On the other hand, however, the absence or abundance of perspiration has no appreciable influence on the variations in temperature during movement. Rest, after a given exercise, always determines a fall in the rectal temperature, more considerable and more rapid the shorter the exercise. All exertion which causes a great acceleration of the pulse and respiration lowers the peripheral temperature (mouth, axilla, groin), but the fall is immediately recovered from on rest, the rectal and peripheral temperatures becoming equalized, or resuming their normal difference —about two-thirds of a degree Fahrenheit. The greatest elevation by exercise which was met with amounted to 103.2° F., in the case of a celebrated runner, aged thirty-one years, who had just run eleven miles in an hour and a half without stopping, and without any other effect than an elevation of the pulse to 145. If the rectal temperature is below 98.6°, a moderate exertion, such as a gentle walk of a mile on level ground, raises the temperature up to the normal, even though the necessary rise amounts to 1½° F. But if the temperature is already above 98.6°, the same exercise will not raise the temperature more than .4° or .8° F. In a rapid ascent the greatest elevation of temperature almost always occurs dur-

ing the first half hour; if the ascent is continued, the temperature may remain stationary, may be raised .2°, or may fall .2° or .3°. Some other observations which corroborate the fact that gymnastic exercises cause a rise of temperature are not of special interest. The account of the investigations has been communicated to the French Académie des Sciences.—*Lancet*, Dec. 4, 1880.

Materia Medica and Therapeutics.

Anæsthesia by Application of Chloroform to the Skin.

Dr. BROWN-SÉQUARD, who has recently brought before the Society of Biology an extremely interesting series of observations (see MEDICAL NEWS AND ABSTRACT, Jan. 1880, page 17), indicating the somniferous and anæsthetic influence of chloroform, when applied to the skin of guinea-pigs, showed, at the sitting of November 20th, that the effects are not produced through the blood, but through the nervous system; since, after division of the spinal cord, the effects were found to be absent when the chloroform was applied behind the seat of the medullary lesion, but to be present when it was applied in front of the lesion.—*British Med. Journal*, Dec. 18, 1880.

Eucalyptus Oil as an Antiseptic.

Dr. BASSINI contributes to the *Annali Universali di Medicina e Chirurgia*, September 1880, an exhaustive article on eucalyptus oil as an antiseptic. He was induced to experiment on this substance by some suggestions made in the *Centralblatt für Chirurgie*, 24th January 1880, in which it was proposed to supersede the use of carbolic acid by the above disinfectant. Eucalyptus oil is an ethereal preparation, citron colored, possessed of a penetrating odor, and mixing easily with alcohol or paraffin. The most practical method of using it, however, was found to consist in mixing the oil with a small quantity of carbonate of magnesia, after which it could be made to readily dissolve in water in the proportion of about 1 per cent. The author's experiments extended over six cases of intentional wounds in animals, and six surgical operations in the human subject, comprising removal of a breast, opening of a chronic abscess in the neck, hydrocele (two), removal of a fibro-lipoma, and a large incised wound of the leg. The observations were not continued further, the result obtained having been considered very unsatisfactory. The author thus sums up his conclusions. 1. Eucalyptic dressing (10 parts of eucalyptus oil as above prepared to 100 parts of wax or paraffin spread on gauze) causes intense annoyance to the greater number of patients by its disagreeable and penetrating odor. 2. Infiltration takes place much more readily with this dressing in the lips of the wound and surrounding tissues, and consequently there is a greater tendency to suppuration. 3. In certain cases, on removing the dressings, an odour of putrefaction was perceived, which showed that the antiseptic qualities of the substance could not be great. 4. The frequency with which eczema appeared on the parts covered by the dressing leads the author to suppose that this substance must have some specific action on the skin.—*London Medical Record*, Dec. 15th, 1880.

Tripolith—a Substitute for Plaster of Paris.

Prof. VON LANGENBECK introduced a new material for fixative dressings at a recent meeting (November 7th) of the Berlin Medical Society. Tripolith, so called on account of its hardness and power of resistance, was discovered by Mr.

B. von Schenke, of Heidelberg, in the course of last summer; and was exhibited, and obtained a premium, at the Exhibitions in Brussels and Mannheim. It was originally intended for stucco and decorative purposes, for which, on account of its greater lightness after drying, and its power of withstanding damp, it is said to be better adapted than plaster of Paris. Its mode of fabrication is not known. but its chief constituents are calcium and silicium, with a minute portion of iron oxide. Tripolith forms a gray powder, which to the touch is finer and softer than plaster of Paris, although of the same weight in the rough condition. An unfortunate accident in Berlin first led to its introduction into surgical practice. The local agent of Messrs. von Schenke broke his arm, and Professor Krönlein, who treated him, applied a plaster-of-Paris dressing. In due course, the dressing had to be changed, and the patient then remarked that he knew of something which would prove better than the plaster of Paris, and accordingly a tripolith dressing was applied. It answered so well, that since this time it has constantly been used at the Royal Clinical Hospital and also in private practice. Tripolith bandages are prepared and applied exactly in the same manner as their plaster prototypes. After the limb has been wrapped in a flannel bandage, gauze bandages filled with the powder are soaked in water and applied in the usual manner. A little thin solution of tripolith is then rubbed in. The charged bandages must not remain too long in water, nor must the mixture be made too thin, nor stirred too much. The advantages of tripolith over plaster of Paris are the following: 1. Tripolith appears to absorb moisture from the atmosphere less freely than plaster, and its power of setting is not lost even after long exposure to the atmosphere. The first lot received from Heidelberg was forwarded in a common sack, in which plaster of Paris would infallibly have been ruined. 2. Tripolith bandages are lighter, and therefore pleasanter to the patient. Thus an equal volume of liquid plaster of Paris, fresh, weighed 604 grammes; of liquid tripolith, 568 grammes. When dried the plaster weighed 470 grammes, the tripolith 413 grammes. Thus tripolith is about 14 per cent. lighter than plaster of Paris. 3. Tripolith dressings harden more quickly than plaster. While a bandage made with the best plaster requires ten to fifteen minutes before it is quite set—and in wet weather often remains soft for hours—tripolith sets completely in three to five minutes. On the other hand, it gives off vapour for many hours, and even after twenty-four feels moist to the touch. 4. Once hard and dry, tripolith absorbs no more water. A piece of dried tripolith dressing undergoes no change when laid in water. It would be possible, therefore, to allow a patient to bathe in his tripolith dressing, provided means be taken to prevent the water getting up inside it, by means of an India-rubber covering; while as regards plaster it is necessary to paint it with dammar varnish in order to make it waterproof. 5. Tripolith is a trifle cheaper than plaster of Paris.—*Med. Times and Gazette*, Nov. 27, 1880.

Vesical Irritation from Blisters.

At the Paris Société de Médecine Pratique (*L'Union Med.*, Nov. 23, 1880), M. JULLIARD observed that it had been recommended, in order to prevent the action of cantharidine on the bladder, to mix some bicarbonate of soda with the emplastrum lyttæ, but that this was difficult to do in Paris, where the blisters are spread on plaster; but the same end is obtained by adding some liquor potassæ of the British Pharmacopœia. He also recommends, on the application of a blister, that some alkalized mineral water should be drunk. M. Aubrun believed that the irritation is produced by allowing the blister to remain on too long. He thinks that the addition of camphor is useless. He is in the habit, when he

applies a blister, to have the skin first well rubbed. The blister will then take at the end of five or six hours as well as it would otherwise have done in twelve hours; and when he has acted in this way he has never met with vesical irritation.—*Med. Times and Gaz.*, Dec. 11, 1880.

Pilocarpine in Skin Diseases.

Prof. PICK, of Prague, communicates to the *Vierteljahrschrift für Dermatologie und Syphilis*, I. 1880, an interesting paper on this subject. Various salts of pilocarpine were employed, especially the muriate, about ½ grain being administered by the mouth or subcutaneously. When protracted sweating was desired, the remedy was taken twice a day, the patient being confined to bed. In other cases confinement in bed was not insisted on; and when warm weather exercise out of doors was permitted; the best time for giving it seemed to be one or two hours after the morning and evening meal. When the remedy had been continued three or four weeks, the effect became less marked, and the dose had either to be increased or the medicine intermitted for some days, when the same dose was again quite efficacious. An important difference in the order of appearance of the physiological effects was seen in some instances. Of 30 individuals, in 21 the internal administration caused first increased flow of saliva and afterwards sweating, while subcutaneous injection induced sweating first, then salivation. In the remaining 9 both methods caused salivation first. Continued use of pilocarpine exerted an important influence on the oiliness of the hair and on its growth. The skin became softer, more pliant and satiny; comedos and papules of lichen pilaris could be more easily pressed out or got rid of, the scurfiness of the scalp became less or disappeared, the hair was less brittle, the new growth of lanugo hairs changed more rapidly into dense, properly pigmented ones. Under employment of the drug for months the general condition of the patient was not impaired; indeed, the appetite improved, and he was better nourished. In prurigo (of Hebra) pilocarpine alone had little effect, but this was otherwise when its use was combined with that of woollen clothing, so as to induce free sweating, which was at first manifest only in the sound parts, after a time also in the portions of the body affected with prurigo. Clinical experience agreed with that of the patients themselves when they declared that when, after a few days' use, a material amelioration of their condition declared itself, the itching also continually grew less, in the end entirely to disappear. The other symptoms also underwent improvement, such as the glandular enlargements, the dry and thickened condition of the skin. The average period required to attain this result was sixty-five days. The effect was more rapid when the employment of pilocarpine was combined with that of other remedies found useful in prurigo, as tar, Vleminx solution, glycerine of starch, etc. As to the curative influence of pilocarpine, the disease recurred at longer intervals after its use than after the employment of other measures, and the outbreaks were less severe when they did occur. While not absolutely curative, therefore, it is possible to attain by its use a more favourable result than when purely local treatment is made use of. Whether, if long continued, the disease would be finally worn out remains unsettled. Pilocarpine exerted no influence on psoriasis, though observations were made in 25 cases. In eczema it produced a deleterious influence when employed during the moist stage or too soon after its cessation. It caused a return of the weeping, and even a spread of the eczema to new parts. In chronic cases, however, where there was little more than scaling, itching, and infiltration remaining, the use of pilocarpine caused these to disappear more rapidly than they would have otherwise done. Subcutaneous injections of pilocarpine cured two cases of

pruritus senilis, causing disappearance or lessening of the itching for some hours, thus rendering sleep possible and imparting both physical and mental strength. A case of chronic urticaria which had resisted other remedies yielded to pilocarpine. From what has been said as to its effect on the condition of the skin and growth of the hair, as might be expected, it seemed to hasten recovery from the baldness of alopecia areata, while in ten cases of alopecia pityrodes (seborrhœa) the results were even more favourable.—*Edinburgh Med. Journal*, Nov. 1880.

Medicine.

Case of Combined Measles and Scarlatina.

Dr. De Giovanni records (*Gazetta Medica Italiana*, October 9th) an interesting case of measles and scarlatina occurring synchronously. The patient was a girl aged 10 years, and the symptoms of measles were, on the whole, the predominant ones during the course of the attack. On the third day after measles had been diagnosed, a bright red rash diffused itself over the abdomen and legs, presenting all the appearances of scarlatina. A curious feature in the case was that the upper part of the body was throughout covered with a distinct morbillous rash, while in the lower the rash was that of scarlatina; at the confines of the two eruptions, they were more or less merged in each other. On the eighth day there was paralysis of the bladder, and the urine was for several days albuminous. The patient became convalescent about the twelfth day. The author remarks that the presence of the one exanthem did not in any way appear to affect the course which the other would have pursued had it occurred alone.—*London Medical Record*, Dec. 15th, 1880.

Ear and Eye Disease on Relapsing Fevers.

In a recent epidemic of relapsing fever at Königsberg Dr. Luchhau has investigated the frequency of ear and eye complications. Since no less than three hundred cases were treated in the town hospital, the field for observation was unusually favourable. Only one hundred and eighty cases were specially examined as to the existence of ear complications, and these were found in fifteen only, and in all the middle ear was the part affected. In most cases there was suppuration, and the pus was evacuated through the tympanic membrane. In most cases of disease of the middle ear in acute maladies the inflammation appears to arise by extension from the throat; but it was found that, in relapsing fever, pharyngeal catarrh is absent, as a rule, in the cases in which the middle ear suffers, and there was no evidence of disease of the Eustachian tubes. The prognosis is not unfavourable if prompt treatment is adopted.

Only six cases presented eye symptoms out of the hundred and eighty examined (3½ per cent.) In three there was iritis, which was unilateral in every case. All these cases did well. In one case, however, some weeks later the patient complained of failure of sight, and opacities were discovered in the vitreous. In two other cases optic neuritis occurred. In one the affection was discovered in the first relapse. The second relapse was severe, and some time afterwards there was atrophy of the optic nerves, and vision was reduced to $\frac{1}{10}$. In the other case the neuritis also occurred during the second febrile attack; a few days after it had ceased the swelling of the optic papilla was discovered, dirty-red in colour, with arteries narrowed, and veins distended and somewhat tortuous. Vision was reduced to $\frac{1}{3}$ in one eye and $\frac{1}{2}$ in the other. Another patient came

into the hospital during the first relapse with iritis and hypopion. The ocular trouble healed completely, but after the relapse the patient insisted on leaving the hospital, and passed though the second relapse at home, under very unfavourable conditions. When it was over he returned to the hospital with double irido-cyclitis. Numerous thick flakes were seen in the vitreous, the fundus was very indistinct, but the papillæ were seen to be red and swollen, and there were numerous retinal hemorrhages. The account of these cases is published in the October number of Virchow's *Archiv.*—*Lancet*, Dec. 11, 1880.

—

Nerve Stretching in Locomotor Ataxy.

Hitherto, little success has attended the employment of the various therapeutic measures designed to arrest the progress or relieve the symptoms of locomotor ataxy. Of all its symptoms, the most urgent in their demand for relief are the darting pains which characterize its early stages, and frequently accompany its entire evolution.

Encouraged by the success which has followed the operation of nerve-stretching for neuralgias of various origins, Langenbeck, more than a year ago, stretched both sciatic nerves, and afterwards both crurals, with the result not only of obtaining complete disappearance of the pains, but also cessation of the motor incoördination. A second case was reported by Esmarch, who stretched the nerves in the axilla for pains in the forearm; and, in this case, too, the motor incoördination disappeared completely. A third case has been published by Erlenmeyer, in which stretching both sciatic nerves failed to influence beneficially either motion or sensation.

A fourth case was shown recently to his class by M. Charcot, at the Salpêtrière, an account of which is published in *Le Progrès Médical* (No. 50). The patient was under the care of M. Debove. He was in an advanced stage of the disease, having been bedridden for eighteen months. The pains were very severe, preventing sleep, situated in the upper as well as the lower extremities; and had required constant injections of morphia, in large doses. The motor incoördination was limited to the lower extremities; the patient could not stand at all. The patellar reflex was absent on both sides; there was extreme myosis, without visual defect, in both eyes. Cutaneous sensibility was deadened; there were no anæsthetic patches. There was loss of the sense of the position of his lower limbs. The left sciatic nerve was selected for operation, on account of the pains being more severe on the left side. It was exposed in the middle third of the posterior aspect of the thigh, and violently and suddenly elongated. The wound was dressed antiseptically. The operation was performed without chloroform, as experiment has shown that pinching a nerve violently causes momentary arrest of the circulation and respiration; and it was feared that this arrest might be dangerous to a patient under chloroform. However, the patient did not suffer much pain, owing to the extent to which he was saturated with morphia. The results were very remarkable. The darting pains had ceased completely, and the motor incoördination had nearly disappeared; but the tendon reflexes and the myosis remained unaltered. The patient could touch M. Charcot's hand with either foot when held a couple of feet above his bed; and, when assisted, could stand upright, and even walk a few paces.

M. Charcot remarked that we do not know how this operation effects this result; but this matters little. The point of importance is, that nerve-stretching appears likely to be an operation of much service to the unfortunate sufferers from ataxy.—*British Med. Journal*, Dec. 25, 1880.

Spinal Paralysis in the Newly-Born.

In the *Archiv für Gynäkologie*, Bd. xvi. s. 87, LITZMANN makes a contribution to our knowledge of this subject. He appends his observations to an account of a case observed by him in Kiel. The presentation was breech. The pelvis was not particularly small, the diagonal conjugate measuring 4 7/8 inches, leading to an assumed conjugate of 3½, the type being justo-minor. The extraction of the body required to be hurried on account of absence of pain and arrest of the circulation in the cord while the body of the child was passing through the pelvis. The child, on being delivered, was deeply asphyxiated. The delivery required no great amount of force to be exerted upon the spine. The asphyxiated child was quickly brought round, and cried loudly. It cried a great deal in the course of the forenoon, and was very restless. Inspirations were irregular and crampy. In the afternoon both legs were completely paralyzed, sensation and reflex sensibility were arrested; the belly muscles were also more loose than usual, and the belly distended. Other symptoms of paralysis were detected. The child shortly improved somewhat, however; but in spite of care and prolonged application of electricity, direct and indirect, there remained considerable permanent paralysis. After a review of the literature of the subject, in which special attention is directed to the work of Little, the author maintains that during severe deliveries which are accompanied with deep asphyxiation of the child, extravasations frequently take place into the meninges of the brain and into the brain tissue, as also into the membranes of the cord, during the delivery, which present themselves in the early years of life as paralyses more or less severe in character. He insists upon greater attention to cases of the kind, and considers that those extravasations may take place quite independently of any force used at delivery.—*Edinburgh Med. Journal*, November, 1880.

—

Some Points in the Clinical History of Effusion into the Pleural Cavity.

At a late meeting of the Medical Society of London (*Lancet*, Dec. 11, 1880), Dr. BROADBENT read an interesting paper on this subject, of which the following is an abstract. He first enumerated and explained the relative importance of the physical signs of pleural effusion, and pointed out that the curved line of dulness was due to the manner in which the lung shrinks around its root, and as the fluid rises the vocal resonance and vibration become exaggerated over that part of the chest-wall where the lung is still in contact. When the cavity is full of fluid the respiratory murmur may be conducted for a short distance across the back from the unaffected lung. Sometimes, however, the lung was prevented from collapsing by adhesions, by consolidation, or congestion: and he believed the persistence of bronchial breathing in such cases was due to imperfect collapse of lung, although the fluid was in large amount.

The chief point he wished to urge was that while the ordinary signs of effusion into the pleural cavity—dulness, extinction of vocal fremitus, diminution of vocal resonance, and limitation of bronchial breathing to the region of the root of the lung—show that the lung retreats and shrinks before the fluid, loud tubular breath sounds at the base of the lung posteriorly and over the lateral and anterior aspect of the chest show that the lung has not entirely retreated, but that it retains a certain volume, and is more or less deeply immersed in the fluid. The patency of the bronchi and the partial condensation of the lung favour the transmission of sonorous vibrations. It is in these circumstances that ægophony is heard most distinctly and widely—from the thin layer of fluid intercepting some vibrations and transmitting others—conditions which ordinarily exist only in the earlier

stages of effusion. In some of these cases there may occur some degree of vocal vibration at a period when the amount of fluid is sufficient to give dulness on percussion over the entire lung. Paracentesis would be of comparatively little value in such conditions, for the quantity of fluid is small, and the consolidation of the lung would persist after its removal; and most cases of this sort get well without resort to paracentesis. In one such case only thirty ounces of fluid could be withdrawn. The conditions are met with in the pleural effusion of renal disease, often accompanied by congestion, and partial consolidation of the lung preventing its collapse; also, in effusions which rapidly become purulent, as in empyema in children. Apart from these cases, the signs indicative of a large congested lung deeply immersed in the fluid are prognostic of rapid absorption, and Dr. Broadbent had seen this now in a sufficient number of instances to enable him to predict with considerable confidence the recovery of the patient without paracentesis and in a comparatively short time. One of the first steps towards recovery is a rather sudden disappearance of the tubular breathing and the substitution of the more ordinary signs of simple effusion; and it is probable that the congested lung has relieved itself by diffusion of serum into the pleural cavity, and that the amount of fluid there is actually increased.

In conclusion, Dr. Broadbent stated the rules which guide him in recommending paracentesis. It should be resorted to at once when there is serious continued or paroxysmal dyspnœa; but in the absence of urgent symptoms a week or ten days may be given after one side of the chest is full, on the chance that absorption may set in, and a longer period still, when the lung has not greatly shrunk. Old age, phthisis, or a phthisical tendency, are reasons for early tapping, as also is the existence of disease of the kidneys. The spot for puncture is the eighth space, in a line with the angle of the scapula, and he had come to prefer the common trocar and canula, with antiseptic precautions, to the aspirator. The whole of the fluid should never be removed, or attempted to be. Where the effusion has lasted some time, frequent partial emptyings are to be preferred.

Dr. C. T. Williams referred to a case of pleural effusion with presence of marked bronchial breathing and vocal vibration, and alluded to the valuable aid in diagnosis rendered by the use of a hypodermic syringe.

Dr. De Haviland Hall mentioned a case of sarcomatous growth filling the pleural sac and collapse of lung, yet with presence of vocal fremitus. In one case he had withdrawn 107 ounces of fluid, and he asked the author as to the amount he would recommend to be withdrawn.

Dr. Habershon spoke of the various forms of pleural effusion—*e. g.*, in renal and in cardiac disease, secondary to pneumonia or due to primary pleuritis. He recalled a case of Dr. Addison's where a small area of bronchial breathing existed, surrounded by complete dulness and absent breath-sounds. The autopsy revealed a portion of lung adherent to the chest-wall at that spot. He pointed out that many cases recover if left alone. If there were high temperature, hectic fever, and tendency to tubercular disease, and if dyspnœa were present, he would advise paracentesis, especially if empyema were suspected.

Dr. Hare said the physical signs were often misleading, especially in children; the presence of vocal fremitus and respiratory murmur on the affected side was only to be accounted for by conduction from the healthy side, through the compressed lung and fluid.

Dr. Wharry asked how far vocal fremitus and tubular breathing were indications of the existence of uncollapsed lung in the fluid. He had seen at least one such case where these signs were absent. What were the author's reasons for assuming that exudation took place from the lung into the pleura in certain cases?

Dr. GILBART SMITH agreed with Dr. Hare as to the difficulty of diagnosis in children. He instanced a case where the lung was wholly collapsed, notwithstanding presence of fremitus and tubular breathings, and asked whether a purulent effusion did not conduct vibrations better than a serous one. He also asked whether the disappearance of these signs would not be better explained by an increase in the effusion and pressure on the lung than by an exudation from the lung itself.

Dr. BROADBENT, in reply, said he had not seen cases of vocal vibration and bronchial breathing with collapsed lung, nor could he explain such. The persistence of vesicular breathing implied the existence of a non-collapsed lung. He did not consider that increase of pressure explained the disappearance of bronchial breathing, for almost invariably improvement quickly followed—ushered in by returning apical resonance. He had not practised injections into the chest in serous effusions, but had frequently and with benefit employed solutions of iodine in cases of empyema. He now preferred to use the simple trocar inserted near the angle of the scapula; this allowed of the withdrawal of the right amount of fluid, while the entrance of air did no harm. If the aspirator were used it was his practice to stop as soon as the patient became distressed or attacked with cough. Eighty-four ounces was the largest amount he had ever drawn off.

—

Sudden Death in Pleuritic Affections.

Dr. LEICHTENSTERN (*Deutsches Archiv für Klin. Medicin.*, Band iv. 4 Heft) discusses a number of cases recorded in medical literature of pleuritic patients, in whom severe syncope and sudden death have occurred, with the view of explaining the causes; and he arrives at the following conclusions. Sudden death or severe attacks of syncope in cases of pleuritic effusion have sometimes their origin in embola of the pulmonary arteries. In other cases, no pulmonary embola exist, but voluminous and far-extending thrombi in the right auricle and ventricle, and in the superior vena cava. The generally prevailing view that left-sided effusion has a greater effect in disturbing the circulation than effusion on the right side, is incorrect. On the contrary, extensive exudation on the right side causes greater disturbance of the circulation by pressure on the large vessels, and on the right auricle and ventricle than does considerable effusion on the left side. And the opinion that cases of sudden death and severe syncope are more frequent in left than in right exudations, is contradicted by statistics. Of fifty-two cases, in thirty-one the exudation was on the right side, and in twenty-one on the left. Cases of sudden death, apoplectic attacks in pleuritic effusion, sometimes arise from embolism of an artery of the brain, or its consequences. In a great number of sudden deaths with pleuritic exudation, we are not yet in a position to explain the cause. The fatty degeneration of the muscles of the heart, the anæmia of the brain, and the œdema of the lung do not suffice for an explanation. To anæmia of the brain as a cause, those cases only can be assigned in which the raising of the sick person from the horizontal position has been followed by severe syncope ending in death. Various causes which sometimes quite interrupt or impede the flow of blood to the left heart, such as a severe paroxysm of coughing, vomiting, lifting heavy burdens, may give rise to a suddenly fatal anæmia of the left heart, and secondarily of the brain. The anæmia of the lungs or brain found in many cases is only of secondary importance. It frequently happens after thoracentesis with aspiration that an anæmia is induced in the partially distended lung; and this may lead to death by asphyxia. In sudden death, during or immediately or a short time after thoracentesis by aspiration, the cause is anæmia either of the heart or of the brain.

In cases in which severe syncope and sudden death are observed during the irrigation of the pleural cavity, the cause is either direct mechanical concussion of the easily exhausted heart by the stream of water thrown in, or shock. The washing out of large empyemic cavities with strong solutions of carbolic acid may cause severe collapse, and perhaps death, due to the rapid absorption of large quantities of the acid.—*London Medical Record*, Dec. 15, 1880.

—

Retarded Signs in Pneumonia.

Dr. TYSON (of Folkestone), at a recent meeting of the Clinical Society of London (*Lancet*, Dec. 18, 1880), read notes of cases of acute pneumonia, in which the usual physical signs of the disease appeared late in the case.—Case 1. A man, aged sixty-four, caught cold whilst driving on April 4, 1880, and next day was compelled to give up work. He was seen for the first time on the 8th, when he complained of pain in the chest, and expectorated some tenacious mucus. There were no abnormal physical signs. Temperature 103; pulse 88; respiration 30; urine albuminous. On the 11th slight dulness appeared at the base of the left lung; fever was high. On the 12th (eight days after the chill) there was well-marked dulness, bronchial breathing, and bronchophony. He was very feeble, and died on the 15th.—Case 2. A female, aged twenty-five, in Guy's Hospital under the care of Dr. Pye-Smith, taken ill three days before admission, when the temperature was 104°. Signs of pneumonic consolidation appeared on the sixth day, and death took place on the seventh. There was gray hepatization of the right upper lobe. — Case 3. A male aged fifty, in whom no dulness was discovered till the sixth day. Death occurred on the tenth day. In two other cases Mr. Tyson had marked the absence of physical signs until the fifth day. He referred to the statement made by Dr. Bowles, that in asthmatical subjects attacked with pneumonia dulness often did not develop till four or five days after the seizure. After quoting passages from Ziemssen's Cyclopædia and Trousseau's lectures to show that such a late development of physical signs was not generally acknowledged, he concluded by stating that this retardation of signs occurred more frequently than was generally supposed, and might be attributed to the central parts of the lung being primarily affected. In such cases the onset of the attack, the pyrexia, and the altered pulse-respiration ratio should be relied on as diagnostic points.

Dr. F. TAYLOR confirmed the author's statement as to the relative frequency with which the physical signs appeared late in the disease, and quoted a case which came to the out-patient department with a history pointing to pneumonia. The physical signs were not apparent, although it was about the fourth day; but the patient coughed up some rusty sputa and was admitted. Soon afterwards physical signs became developed. In another case the delayed signs appeared before the rusty expectoration.

Dr. ANDREW CLARK said the paper was an important contribution to the literature of the subject, for anomalous and capricious cases of pneumonia were imperfectly recorded; but he did not think it added much to the knowledge of experienced men. He was constantly meeting with cases in which the constitutional evidence of pneumonia long preceded the appearance of local signs. He would mention three such cases. One was a case of a gentleman he saw in consulation with Dr. Stephen. After a slight rigor the temperature rose to 101°, and for seven days there was no evidence of the disease, except the general distress, rapid breathing, and altered pulse-respiration ratio. The physical signs of pneumonia appeared on the eighth day. Another case was that of a gentleman, aged eighty, at Southsea, seen with Mr. Potts and Sir W. Gull. After a chill

there was a period of ten days marked by irregular pyrexia, malaise, and hurried breathing. On the eleventh and twelfth day slight friction was heard below the angle of the right scapula, followed by dulness and tubular breathing. The patient recovered. A third case was one he saw with Dr. Buzzard, when the patient had been ill for six days with pyrexia without the local signs. He did not think it necessary to have all the physical signs present to diagnose pneumonia; and that in cases of central pneumonia the disease was too far removed from the surface to yield these signs. With a history of chill, with distress and prostration, with fever, and a disturbed relation between pulse and respiration, one may be absolutely certain that the case is one of pneumonia.

Dr. HABERSHON concurred that in some cases the general symptoms, with hurried breathing and rusty expectoration, without physical signs, must be taken as sufficient for diagnosis. No doubt such anomalies were explained by the disease being deep-seated, so that the physical signs are obscured, just as a severe pleurisy may involve the surface of the diaphragm without any friction being audible. When the physical signs do become manifest, the pneumonia has probably extended to the periphery.

Dr. ANDREW CLARK added that pneumonia might be diagnosed from the general conditions; because in a large number of cases there is neither cough, nor expectoration, nor pain in the side.

Dr. DE H. HALL, some five or six years ago, had recorded two cases of apical pneumonia marked by severe head symptoms. One was a man, aged nineteen, who was comatose for six hours; the other a child, who had repeated convulsions; and it was only on the fifth or sixth day that distinct tubular breathing appeared. One reason for the severity of these cases, as compared with those which ran a more typical course, might be found in the greater amount of lung involved in central than in peripheral pneumonia.

Dr. BURNEY YEO said that such cases suggested the question whether the lung condition was not secondary to a constitutional disorder.

Dr. GOODHART observed that the question was a complicated one, so many conditions occurring under which the physical signs varied. In old people the late appearance of these signs was attributable to the presence of emphysema. At the same time he agreed with Dr. Yeo that blood-poisoning might be the primary condition to which the pneumonia was secondary. Some years ago he examined the body of an old man, who died three or four days after taking a chill. There was only a slight amount of pneumonia, and the only interpretation he could put on the case was that the chill, arresting the function of the skin, had caused blood-poisoning, and that sufficient time had not elapsed for true pneumonia to be fully developed.

Mr. TYSON replied, that all his cases ultimately developed the signs of ordinary pneumonia. The last case he had seen was in a child, five years of age, with high temperature for six days, without pneumonic symptoms. He had written the paper because all the authorities he had consulted did not mention the proportion of cases in which this delay in the development of physical rigors occurs; although many state that they have seen such cases.

The Production of Phthisis by Inhalation.

In 1877 Dr. TAPPEINER[1] published an important series of observations on the production of tubercular disease in the dog by the inhalation of the sputa of persons suffering from phthisis. He has lately extended his investigation by an

[1] See Monthly Abstract, 1878, p. 252, and 1879, p. 15.

attempt to ascertain whether the inhalation of material from scrofulous glands is capable of producing the same effect, and the results have been published in Virchow's *Archiv*. If scrofulous diseases are indeed identical with tubercular processes, as it is fashionable now to assert, the effect of inhalation of gland-pus ought to be the same as that of phthisical pus. The material for the experiments was pus from a scrofulous boy, five years of age, with suppurating glands. Half a gramme of pus was obtained daily, mixed with 100 grammes of water, and the dogs were made to inhale the atomized mixture for a quarter of an hour during about ten days. For purposes of comparison, two dogs were similarly treated with phthisical sputa. These two, and one of the dogs treated with the gland-pus, were killed and examined twenty-three days later. The organs of the latter were found to be perfectly normal, although the animal had presented a cough and loss of weight. In the two dogs treated with phthisical sputa, tubercular nodules were found in both lungs and spleen; their nature, from the microscopical characters, was beyond doubt. The two other dogs treated with gland-pus were killed and examined thirty-three days after the commencement of the inhalation, and the organs were also found free from tubercle. The same negative result was obtained in the case of two dogs killed on the twenty-ninth day after the inhalation of gland-pus.

Further investigations were made as to the period of incubation from the commencement of the inhalation of phthisical sputa until the tubercles are distinct in the lungs. One dog was killed on the thirteenth day after the commencement of the inhalation; it had coughed for eight days, and had lost three-quarters of a pound in weight; no tubercle was found in the organs. In another dog, killed on the nineteenth day, also, no tubercle was found. It thus appears that the period of incubation is more than nineteen days. Another dog, treated at the same time and in the same way with phthisical sputa, was killed three months after the commencement of the inhalation, and abundant tubercles were found in the lungs and pleuræ.

By the suggestion of Professor Waldenburg, two other dogs were treated with sputa from simple chronic bronchitis, fifteen grammes daily for ten days; and they were killed on the twenty-eighth day after the commencement of the inhalation. The post-mortem examination showed both lungs to be perfectly normal, without a trace of tubercle. The experiments were made at Berlin, and the pathological results ascertained by Grawitz, Israel, and Friedlander, under the supervision of Virchow, so that the facts appear to be beyond question.

The conclusions drawn by Tappeiner from these experiments are: (1) The inhalation of phthisical sputa by dogs, even in small quantities, produces with certainty tuberculosis of the lungs, with or without general tuberculosis, especially of the spleen. (2) The stage of incubation is, in dogs, longer than nineteen days, but shorter than twenty-three days. (3) The inhalation of scrofulous caseous pus from glands produces no infection—a fact which indicates an essential difference between scrofulosis and tuberculosis. (4) The inhalation of the sputa from chronic bronchitis is equally ineffective.

The facts ascertained in these experiments are certainly of a very important nature. The period of incubation, however, can hardly be fixed from so small a number of experiments, since it may not improbably be subject to considerable variation. But these observations constitute experimental confirmation of the infection of phthisis, to which many clinical facts point, and they indicate the probable mode by which the infection is produced. The difference in the effect of scrofulous pus and phthisical sputa, if not entirely conclusive as to the difference between tubercular and scrofulous affections, indicates that we must still pause before we abandon the older view. That view rests, we must remember,

on clinical facts, which were so well described long ago by Sir William Jenner; and these facts must be explained away if we are to accept, as Dr. Hilton Fagge would have the members of the Pathological Society accept, the results of inoculation experiments as conclusive evidence of the identity of the two conditions.—*Lancet*, Nov. 27, 1880.

—

Case of Gonorrhœal Endocarditis.

Dr. CIANCIOSI records a case of this rare complication in *Bulletino delle Scienze Mediche*, September, 1880. The patient, whose family history was good, contracted a gonorrhœa, which was checked almost immediately by strong astringent injection. The disappearance of the discharge was, however, quickly followed by an undefined feeling of malaise, which became aggravated, and finally accompanied by intense cephalalgia and pyrexia. Auscultation showed at this period a systolic murmur most distinctly heard at the apex. Respiration, 28; temperature, 39° centigrade (102.2° Fahr.). The diagnosis of endocarditis was arrived at, of which no other explanation seemed possible than that it was dependent on the suppression of the gonorrhœal discharge. This shortly afterwards became re-established, and the patient eventually recovered. The author, in explaining the etiology of the attack, exhausts various hypotheses, but eventually adopts that suggested by Klebs in certain cases of rheumatism, viz., an actual emigration of micro-organisms. In this case such organisms found their way into the blood, whence they may have been deposited on the valves of the heart, or in its stroma, with the result of exciting interstitial inflammation, accompanied by the usual train of symptoms.—*London Medical Record*, Dec. 15th, 1880.

—

Two Cases of Intestinal Occlusion Treated and Cured by Electricity.

BOUDET de Paris (*Progrès Médical*, August, 1880) gives two cases of intestinal obstruction successfully treated by electricity. In the first, the patient, aged 15, had just recovered from an attack of peritonitis, when she was suddenly seized with all the symptoms of obstruction, due probably to the entanglement of a loop among the freshly formed adhesions. The usual means having failed to give relief, the faradic current persistently applied externally was tried, but without any result. The patient was in a very critical condition, bringing up everything that was given her by the stomach. During the next forty hours the continuous current was applied about every three hours for half to one hour at a time; the negative pole was in the rectum, and with the positive the abdominal walls were dabbed so as to produce interruptions. During these applications the intestines were noticed to be the seat of lively muscular contractions, and eventually desire of going to stool was experienced. At last an evacuation was obtained, and from this moment convalescence was established. In the second case, the author had to do with fecal accumulation due to habitual constipation from deficiency of muscular power. Electricity, in the shape of internal galvanization as above, and abdominal faradization, was resorted to as a last resource. The result was most gratifying. From the first, intestinal contractions were obtained, and on repetition large quantities of excreta were expelled The author remarks that he has collected fourteen other cases where electricity has proved useful in obstruction. He shows that the superiority of the galvanic current, where paralysis of the intestine exists, is due to the fact that it stimulates much more powerfully the unstriated muscular fibres. The interruptions must be slow, because the contractions of these fibres are not sudden but gradual. Care must be taken not to electrolyze the rectum by using a moderate current. The author used from 8 to 14 Leclanché's.—*London Med. Record*, Oct. 15, 1880.

Double Cystic Kidney with Renal Calculi.

Dr. L. A. Aman and Axel Key relate the following case (*Hygeia*, 1879: and *Nordiskt Medicin. Arkiv*, Band xii.). The patient, a man aged 37, had first voided a renal calculus in 1871, and another in the autumn of 1872. Since that time his health had been good; but sometimes he had a feeling of weight in the loins and discharged a little gravel. On July 1, 1879, he took cold, and soon noticed that the daily quantity of urine diminished until the 8th, when there was suppression. He was admitted on July 9th, into the hospital at Linkoping: his bladder was then empty. In the course of the next night, he voided about seven ounces of urine with his stools. He complained only of soreness in the region of the right kidney. The urine could not be examined until the 15th, when it was found to contain much albumen. On that day, symptoms of uræmia set in, and he died on the 16th. At the necropsy the mucous membranes were found to be œdematous, and the brain hyperæmic. The kidneys were sent to Dr. Axel Key for examination. They were both greatly enlarged, the left, however, more than the right; and both presented almost complete cystic change. The renal parenchyma remaining in the interspaces between the cysts had a yellow-gray turbid appearance. The pelvis of the right kidney was much dilated, and contained a large nodulated calculus, the lower part of which was rounded, and covered in the orifice of the ureter, which was dilated. The left ureter, at a distance of about two inches from the kidney, was completely blocked up by a calculus of moderate size; below this, the canal was completely strictured by indurated connective tissue, scarcely allowing the passage of a fine sound. Above the stone, the ureter was dilated, and the pelvis and calyces especially were greatly expanded. Dr. Key thinks it remarkable to find such extensive changes in the kidneys of a person who had enjoyed relatively good health up to a fortnight before his death. He regards the cystic change as having been principally congenital, and as having no connection with the formation of the renal calculi and the consequent obstruction to the flow of urine. The renal parenchyma which was found between the cysts had been sufficient for the function of the kidneys. When the renal concretions began to be formed, hydronephrosis was gradually developed, and in connection with it a chronic nephritis with interstitial and parenchymatous changes, which went on for a time without producing any marked disturbance, until at last an acute exacerbation set in and rapidly caused death.—*Brit. Med. Journ.* Oct. 30, 1880.

Sciatica caused by Aneurism of the Abdominal Aorta.

In this case, reported by Garel (*L' Union Médicale*, p. 951), the pains of sciatic neuralgia absorbed the attention both of patient and medical men so entirely, as to leave absolutely unnoted symptoms of aneurism until the day when the patient succumbed rapidly after its rupture. This fact teaches that, in the presence of obstinate sciatic neuralgia, the course of the abdominal aorta should always be minutely explored. Lebert, in a work published in 1865, asserts that pain in the kidneys is often one of the first signs of aneurisms of the abdominal aorta. [See particulars of a similar case shown by Dreyfus to the *Société Anatomique de Paris*, in 1876; other cases cited by Samuel Archer, in the *Dublin Medical Journal*, 1878; and Lediard, in the *British Medical Journal*, 1878.] M. Garel's case also presented an important symptom, a diastolic souffle at the base of the heart, which was not due to insufficiency of the aorta, since the other rational symptoms of this affection were absent. It remains an ascertained fact that aneurism of the abdominal aorta may give rise to the production of souffles in the region of the heart—diastolic or systolic souffles in no way connected with

a lesion of the aortic orifice. Moutard-Martin's cases (*Société Anatomique*, 1845), those of Lepine and Falzer (*Société Anatomique*, 1877), and of Archer (*loc. cit.*) show that these souffles are due to the propagation of sounds produced at the level of the tumour.—*Lond. Med. Record*, Oct. 15, 1880.

Surgery.

Carbolic Acid in Facial Erysipelas.

Dr. ROTHE observes (*Betz. Memorabilien*, 1880, No. 9), that, however efficacious the subcutaneous injection of carbolic acid proves in arresting the course of erysipelas, it is not suitable when the face is the part attacked, for not only does it give rise to considerable pain, but induces a swollen and painful condition of the periphery. For some years past he has been in the habit of using the following application: Acid. carbolic., sp. vini., ää one part; ol. terebinth. two parts; tinct. iod. one part; glycerin. five parts: pencilling the inflamed skin and its vicinity with it every two hours. No pain or sense of burning is produced, and the skin is usually next day pale and wrinkled. The further progress of the disease is more effectually arrested than by any other remedy, any new patches being rapidly effaced, so that in three or four days the facial erysipelas is usually at an end. The pencilled places should be covered by a very thin layer of wadding. When febrile action is present the ordinary internal measures must also be resorted to.—*Med. Times and Gazette*, Dec. 4, 1880.

Peritomy.

At a late meeting of the Ophthalmological Society of the United Kingdom (*Lancet*, Dec. 18, 1880), Mr CRITCHETT read a paper on Peritomy, and gave the following reasons for introducing the subject to the notice of the meeting: First, that during a long career many cases of vascular opacity with granular lids had come before him in which the disease had remained for many years unrelieved, although the patients had been under treatment for considerable periods at various institutions; and secondly, because the operation of peritomy had fallen into unmerited neglect, and was seldom practised. He then proceeded to give a brief sketch of the leading symptoms of the disease, and alluded to the type of patient in whom it most frequently occurs, he having found that it is most prevalent in young adults who had been ill-nourished and neglected; and that it is frequently propagated by direct transmission, so that constitutional defects and local causes contribute in varying degrees to its development. It often exists in a more or less aggravated degree for many years; and the treatment is, as a rule, directed to removing the granular condition of the lids. This may be partially effected by the application of caustic and astringent lotions, but such treatment is rather palliative than curative, and not unfrequently during its progress the case will relapse and the symptoms become even more intensified.

Mr. Critchett recommended—although it might seem contrary to the pathology of the disease—that curative treatment should in the first place be directed to the vascular web, which in these cases covers the upper third or upper half of the cornea, since he believed that the exciting cause of the relapses lay rather in this morbid condition, and that the granular state of the lids was kept in activity by the existence of the above mentioned vascular membrane. He,

therefore, in every case initiates his treatment by performing the operation of peritomy, since he finds that when sufficient time has been allowed (usually from four to six months) for the resulting cicatrix to become dense, white, and atrophied, thus cutting off the vascular supply to the partial pannus, the web gradually disappears, the cornea becomes transparent, and the granulations either take their departure or become much more amenable to ordinary treatment. He was anxious to dwell upon this last point, because for a certain period after the performance of the operation no benefit, but rather the contrary, would usually be observed, and it is only on the completion of the last atrophic stage of the cicatrix that the curative influence is established. He earnestly commended the operation to the attention of his colleagues. Three cases were shown illustrating the effects of treatment at different stages. Mr. Critchett said that he extended the peritomy beyond the pannus—*i. e.*, right round the eye.

Mr. HIGGENS has performed peritomy in many cases without result, and had therefore abandoned it. Possibly he had not observed the case long enough afterwards, and after Mr. Critchett's advocacy he would again perform the operation.

Mr. STREATFEILD asked whether any treatment was adopted for the granular lids?

Mr. CRITCHETT said all the cases had granular lids, but he began by the peritomy, and in a large number of cases the granular condition subsides when the vascularity of the pannus is cured. In other cases the granular lids require additional treatment.

Mr. JAMES ADAMS had long been in the habit of performing peritomy, and was satisfied with the benefit resulting from it. He thought the cases should be selected. He had found that the pannus was not always dependent on granular lids, but the cornea was vascular from the first.

—

Case of Hemiglossitis.

An example of this affection (which, like all similar cases on record, occupies the left side) has been recently treated in the Lariboisière. An œdematous swelling occupied the anterior two-thirds of the left side of the tongue, and a deep-seated lump was sensible to palpation. All the neighbouring parts of the mouth and the teeth were in good condition, there being only present a little redness in the pharnyx and a painful swelling of the submaxillary glands. The functional disturbances consisted in difficulty of speech, nasal intonation, fetid breath, and abundant salivation. It is remarkable that there was no pain in the part, the face or the neck. The exact localization of the disease became more and more obvious in its progress, and while the side affected was divested of its epithelium and appeared of an intense red, the right side retained its natural aspect, its whitish colour contrasting strongly with the other half of the tongue. Under the use of emollient gargles and the chlorate of potash internally, the disease was cured in eight or ten days.—*Med. Times and Gaz.*, Dec. 11, 1880, from *Gaz. des Hôpitaux*, Nov. 27, 1880.

—

Anæsthesia of the Larynx by a New Method.

Dr. ROSSBACH (*Wiener Med. Presse*, No. 40, 1880), being dissatisfied with the ordinary method of producing local laryngeal anæsthesia by the administration of bromide of sodium, on account of the greater difficulty in operating when the patient is listless and drowsy under the influence of that drug, has of late followed another method, which he finds perfectly practicable and more convenient.

His object is to influence the sensory portion of the laryngeal nerves, so as to interrupt conduction through them for a time, and thus induce complete anæsthesia of the larynx. The sensory portion of the superior laryngeal nerve is most easily reached at the point at which it passes through the thyro-hyoid membrane into the interior of the larynx, immediately below the extremity of the greater horn of the hyoid bone; here it is so superficial that a subcutaneous injection of about $\frac{1}{12}$ grain of morphia on each side, at the spot indicated, will produce full local anæsthesia. A simpler method of obtaining the same result is to direct the ether spray from a Richardson's apparatus on the above described points, which can be done on both sides simutaneously, with a double pointed nozzle; in one to two minutes complete anæsthesia is established.—*Glasgow Med. Journal*, Dec. 1880.

Thyrotomy in a Child aged Eighteen Months.

The subject of intra-laryngeal new growths is one of sufficient interest, on account of the intrinsic difficulties of diagnosis as well as treatment, to make all contributions concerning it both welcome and instructive. Dr. NAVRATIL, of Pesth, contributes an interesting paper to the *Berliner Klinische Wochenschrift*, No. 42. After some preliminary remarks concerning some former communications on the same subject, he relates the following case: A male child, who appeared from the history to have been hoarse from its birth, when eight months old got whooping-cough; after the cough had subsided, the hoarseness became more marked. A peculiarity in the voice, and a noisy, laboured respiration, had been noticed, and in the course of the last two months, especially at night, the child had suffered from occasional attacks of dyspnœa. Treatment, which had been of an "anti-catarrhal" kind, had proved quite unavailing. In consequence of this failure, but especially because an extensive ulceration had broken out on the scars of the previously healed vaccination places, a possible syphilitic origin for the dyspnœa was taken into consideration, and anti-syphilitic remedies were accordingly ordered. They proved, however, quite unavailing. Meanwhile, the dyspnœic attacks increased in severity to such an extent that the parents sanctioned a more radical method of treatment. At this time the child was exceedingly emaciated; it presented no signs of syphilis, but it was cyanosed and its breathing was hard and laboured. Tracheotomy was now performed; and although the operation barely lasted two minutes and a half, respiration ceased. After the subcutaneous injection of ether, and other means had been tried, the child gradually revived. Contrary to Dr. Navratil's usual custom, and led thereto chiefly by the child's exhaustion, further operative means (the extirpation of the growth) were not undertaken at this time. Not until four weeks later was the general condition sufficiently improved to warrant any further attempts. A vertical incision was then made over the middle of the thyroid cartilage, which was thus laid open. But between the lower extremity of this incision and the tracheotomy wound, a narrow bridge of tissue was left untouched. The object of this was to secure a more exact adaptation of the edges of the wound and of the vocal cords, and for the better holding in place of the canula when sewing up after completion of the operation. Instead of finding the papilloma, the operator found a cavity lined with mucous membrane, in the form of a shut sac; he therefore passed a bent probe upwards from the canula into the larynx, and in this manner established that the mucous sac (above mentioned) was not the larynx. The sac was then slit up, and the papilloma discovered. It was as large as a medium-sized strawberry, and almost filed the laryngeal cavity. The growth was removed with the hæmostatic forceps, and the place from which it had sprung was then touched with the galvano-caustic; for, owing to the small size of the

larynx, even when widely expanded with sharp hooks, it was found impossible to cut off the mucous membrane itself, which seems to be the best prophylactic against recurrence. The edges of the thyroid cartilage were then brought together (a proceeding which was greatly facilitated by the little bridge of tissue already mentioned), and the wound was covered with carbolic gauze. It may be remarked that there was very little hemorrhage, and that there was not the slightest need to plug the trachea. The after-proceedings were not altogether untroubled, for the edges of the wound separated and became very unhealthy, and there was fever for several consecutive days. On the sixth day (after the operation) fluids came out of the tracheal wound: this was considered as probably due to injury to the posterior wall of the larynx and the adjoining wall of the œsophagus by the cautery. But after two weeks this ceased. The child now began to grow and develop in a remarkable way. Its voice—on stopping the canula—was clear; it could whistle and breathe through the mouth, though only for a short time. The growth, however, began to recur after a period of ten weeks. A metal probe was coated with nitrate of silver, and this was applied twice weekly. The new growth rapidly disappeared under this treatment (but whether permanently or not is not stated). The recurrent growth was much firmer than the original one; and Dr. Navratil considered this a good omen. A similar appearance has been observed in other cases. As a rule, the softer the growth—presumably from greater abundance of the cellular element—the more probable its recurrence after extirpation, and the greater the necessity for excising the basement membrane on which it rests, with a view to prevent this recurrence. This form of growth is very unusual in children. Thus this author had only seen three other cases, aged three and a half, five, and seven years respectively. The case may be regarded almost as unique in so young an infant as the present instance.—*Med. Times and Gazette*, Dec. 25, 1880.

—

Œsophagism.

Dr. ELOY concludes (in the *Gaz. Hebdomadaire*, December 10) an elaborate paper on œsophagism in these terms: "As a result of the consideration of all the cases which we have cited, we come to the conclusion that the most efficacious means for combating this affection, when existing independently of all functional disturbance—that is, œsophagism from a nervous cause, whether local or general—are the employment of catheterism (with or without dilatation) as a mechanical agent, the hypodermic injection of morphia as an analgesic, and the bromide of potassium (either by the mouth or as an enema) as a moderator of the reflex power. Moreover, this last agent will facilitate catheterism, by imparting a greater toleration of the mucous membrane to the contact of instruments."—*Med. Times and Gaz.*, Dec. 18, 1880.

—

Extirpation of a large Retro-peritoneal Fibroma, and of the left Kidney and Supra-renal body which were adherent to it.

Dr. F. B. BUSCHMANN reports this case. The operator was Professor Billroth. The patient was aged thirty-five. The belly was distended; no distinct masses could be felt; palpation gave a feeling of firmness and elasticity, but no distinct fluctuation; the percussion dulness passed without interruption into that of the liver and spleen. The tumour seemed fixed, and no connection could be made out between it and the uterus, which was apparently normal. The size and weight of the tumour caused much suffering, and there had latterly been rapid wasting. There was some bronchial catarrh, but with this exception the other organs were normal. The incision made was twenty centimetres long.

The tumour, which felt as if it contained fluid, was punctured, but nothing came. As the size of the tumour therefore could not be lessened, the incision was prolonged ten centimetres. The tumour was then separated from the surrounding peritoneum by numerous ligatures. The left kidney and supra-renal body, which were quite healthy, were lying in the true pelvis, and were firmly adherent to the tumour, attempts to separate them producing great hemorrhage. The vessels in the hilum of the kidney and the ureter were therefore tied, and it and the supra-renal body removed with the tumour, which weighed eighteen kilogrammes (about 39¾ lbs.). The growth was not pediculated; it had sprung from between the folds of the broad ligament, and grown upwards behind the mesentery. The uterus and both ovaries were normal, and not connected with the tumour. The wound was closed with twenty-nine sutures, and four drainage-tubes put in. Every antiseptic precaution was observed. Symptoms of peritonitis appeared next day, and the patient died in collapse on the fifth day. There was no autopsy. The tumour was found to be a fibro-myoma.—*Obstetrical Journal of Great Britain*, Nov. 15, 1880.

—

Accident to a Lithotrite.

At a recent meeting of the Medical Society of London, Mr. COULSON read notes of a case of lithotrity (Bigelow's operation), in which an accident of an unrecorded kind occurred to the lithotrite. The patient was sixty-eight years of age and had suffered from symptoms of calculus for about seven years. The operation was performed on the 11th inst. The meatus urethræ having been previously incised, a large stone about two inches in diameter was caught and crushed with Bigelow's lithotrite. The stone offered much resistance to the instrument, and the fragments separated with a loud crack. Three or four fragments had been successively crushed when it was found that the screw and two pins by which the lithotrite is fastened to the shaft had given way, so that the two portions of the instrument became separated. No means for connecting the handle with the shaft could be extemporized. By percussion, however, upon the handle the blades were freed as much as possible from the débris, and the instrument removed from the bladder, some injury being inflicted on the neck of the bladder and urethra in its withdrawal. The operation was completed by the fenestrated lithotrite, and fragments weighing 500 grains removed by the tube and aspirator. The operation occupied two hours and ten minutes, a delay of twenty minutes being caused by the accident. No bad symptoms followed, and this was attributed to the complete removal of the fragments having been effected. Mr. Coulston remarked on the enormous power of the blades of the instrument, and the inadequate resistance to the force applied by the screw, due to the imperfect manner in which the handle is connected with the shaft.—*Lancet*, Nov. 27, 1880.

—

Removal of Villous Growth from the Bladder.

Mr. DAVIES-COLLEY, at a recent meeting of the Clinical Society of London read notes of a case of villous growth of the bladder, sucessfully removed by perineal incision. Henry W., aged thirty-two, a shipwright, had suffered from hæmaturia for eight years. At first blood was passed only occasionally, and in small quantities. Latterly the flow had increased, and he had become so weak that for sixteen months he had been unable to work. He was admitted into Guy's Hospital last March. His family history was good. He was strongly built and fairly nourished, but very anæmic. There was a continual desire to micturate, and a feeling as if something always remained behind in the bladder. Blood was passed, sometimes at the beginning, sometimes at

the end of micturition. No stone could be detected, and all efforts to find villous masses in the urine failed. No tumour could be felt per rectum. On April 16, he was placed under ether. Mr. Davies-Colley then opened the bladder by the usual incision for lateral lithotomy. At first nothing could be felt. Then a slight projection was made out on the left side of the fundus, and a cord-like process running from it. In a short time the free end of this process, with a soft pinkish tuft of villi attached to it, was seen at the deeper part of the wound. This was seized with the forceps, drawn out, and the pedicle cut with a pair of scissors close to the wall of the bladder. No other growth could be felt. There was but little hemorrhage during the operation, and some which occurred in the evening was readily arrested by the injection of iced water into the bladder. He made a rapid recovery. In two weeks the urine ceased to flow from the perineum, and soon afterwards the wound healed. When last seen, two months after the operation, there had been no return of the hemorrhage. The irritability of the bladder had ceased, and he was in the enjoyment of perfect health. The tumour grew from the posterior wall of the bladder, at a point about three inches from its neck, and one inch to the left of the middle line. It consisted of a fibrous stalk one-sixth of an inch thick and two inches long, terminated by branching filaments from half an inch to three-quarters of an inch long. These filaments contained capillary loops, invested by many layers of epithelium of a cylindrical shape.

Professor HUMPHRY has recorded in the *Medico-Chirurgical Transactions* a case in which he successfully removed a fibrous polypoid growth from the male bladder. He mentions a similar success in Professor Billroth's practice. The chief difficulty in the male subject is to ascertain the presence of a tumour as the source of hemorrhage. In the present case the diagnosis depended solely upon the long continuance of the bleeding and the absence of other causes. Perhaps the fact of blood passing sometimes at the beginning, and other times at the end of micturition, may assist in the detection of growth. No doubt the villi were in this case sometimes washed into the prostatic part of the urethra, where they were squeezed, so as to give rise to a flow of blood before the urine; while at other times hemorrhage into the bladder was set up by the pressure of its muscular walls upon that part of the growth which lay in its interior.

Mr. CLEMENT LUCAS said that in these cases operative interference was justifable and reasonable. He had thrice performed cystotomy in chronic disease of the bladder with great relief. The diagnosis of villous disease was not assured until a small portion of the growth could be obtained and detected by the microscope. These cases often went on for years without much effect upon health. He had a case under his care for two years; astringent injections afforded some relief. Mr. Durham attempted the removal of a growth from the bladder a few years ago.

Dr. HABERSHON said that the patient on whom Dr. Davies-Colley had operated was very weak and prostrate on admission into the hospital, and it was evident that the hemorrhage came from the bladder, and not from the kidneys. There was often great difficulty in the diagnosis of these cases. He remembered a case in which the symptoms were attributed by one to calculus in the bladder, by another to calculus in the kidney, and by another to cancer. The patient suffered from hæmaturia, and at times intense pain in the penis. After three or four years' suffering a portion of a villous growth was passed per urethram, and all the symptoms ceased. Some pain returned after many years' interval. In other cases hemorrhage continues; and in the presence of such cases it was a great advantage to know that operative interference might be undertaken with relief.

Dr. A. P. STEWART said that about twenty years ago he sent in to the Middlesex Hospital from the out-patient room a woman who had suffered for many months from intermittent hemorrhage from the bladder, at times very profuse, then ceasing for weeks, and then returning. Mr. De Morgan made a digital examination of the bladder, but found nothing. The urine continued to contain blood at intervals, and ultimately the patient died. The bladder, with a pedunculated villous growth, is now in the hospital museum. The reason why it had not been detected by Mr. De Morgan was, that it was attached to the front wall of the bladder immediately under the pubes.

Mr. TEEVAN congratulated Mr. Davies-Colley on the case; the first and only case of successful removal of a villous growth by the knife. Civiale had removed one by the lithotrite. Villous growths were usually attached to the posterior wall of the bladder, whereas polypi were fixed to its neck. The diagnosis of such cases was difficult; and he mentioned one which he had lately seen with Dr. A. Clark, when in catheterism clear urine flowed at first, followed by pure blood and some shreds of villous growth. The patient was old and paralytic, so that attempt at removal of the growth was out of the question. Incision into the bladder for cystitis was done largely in America, and he himself had practised it four times, making the median incision. Perhaps an external urethrotomy would suffice; villous disease was not always fatal. He had seen a case where the mass was spontaneously extruded with recovery.

Mr. BARKER asked whether in the cases operated on by Professor Humphry and Professor Billroth the growths were as pedunculated as in Mr. Davies-Colley's case. In some cases the villous disease is distinctly sessile, and involves a large surface of the fundus of the bladder. Supposing a growth of that variety were cut down upon, it would be difficult to know how to deal with it.

Mr. DAVIES-COLLEY, in reply, said that the tumours removed by Professors Humphry and Billroth were not of the villous kind. Prof. Humphry's was a case of polypoid fibrous growth from the mucous membrane. In his own case had the growth been sessile, no doubt great difficulty would have been experienced, but still, by tearing and scraping much might be removed, and the hemorrhage checked at least for a time. It was generally possible to entangle a small portion of a villous growth in the eye of the catheter, and thus extract it for diagnostic purposes; and lately he had employed the washing bottle used in litholapaxy very effectually for the same purpose.—*Lancet*, Dec. 18, 1880.

—

Washing out the Bladder.

Dr. FISCHER, in a paper on this subject in the *Berliner Klin. Wochenschrift* for November 29, objects to the ordinary double catheter, because, as the stream of fluid always enters the bladder on one side only, the other side of the bladder may not be sufficiently cleansed. To obviate this defect he has modified the instrument as follows: The fluid passes into the bladder at the extremity of the instrument, which is somewhat bulbous and perforated with holes, and it escapes through a slit near the curve of the catheter. The instrument is disinfected in a three per cent. solution of carbolic acid before being introduced. In injecting the fluid he uses the irrigator, and thus the fluid is introduced in a continuous equable stream, and not in jerks as when it is pumped in. He washes out the bladder in cases of chronic catarrh, in order to remove the mucus, etc. He also advocates the injection of cold water into the bladder in cases of atony of that organ. At the commencement of the injection the water must be tepid, but it is latterly introduced quite cold. The cold stimulates the bladder to contraction, and after these injections have been employed for a few times the organ begins

to regain its power. In destructive inflammation of the bladder he washes it thoroughly out before introducing any medicaments. Indeed, he thinks that continual irrigation with diluted remedies might in some cases be desirable.—*Med. Times and Gaz.*, Dec. 18, 1880.

—

Varices in Pregnancy.

M. BUDIN, of Paris, has written an interesting monograph upon the varices of pregnancy. The most common varices are, of course, those of the leg. M. Budin points out that the signs and symptoms of varicosities of the superficial and of the deep veins are quite distinct. Those of the superficial veins are familiar to every one. In the case of deep varices there is nothing to be seen wrong with the affected leg, except that it is increased in size. The patient complains of severe pain in the calf, in the popliteal space, and in the sole of the foot; and there is increased perspiration of the affected limb. If such symptoms as these are rapidly relieved by rest, it is probable that a varicose condition of the deep veins is their cause. These varices are not constant in their mode of appearance. Sometimes they only become troublesome after several pregnancies, and then not till the last months of gestation; but in some women they are noticed in the first three or four weeks; one patient commonly first became aware of her pregnancies by the development of the varices. M. Budin also describes the varices of the internal and external genital organs, of the anus and rectum, of the urethra and bladder, and of the trunk and upper extremities. Hæmorrhoids often cause a good deal of trouble during pregnancy, but not danger; they commonly disappear after delivery. If fissure coexist, it will be best treated by forcible stretching. Varices of some kind occur in from twenty to thirty per cent. of all pregnancies.—*Med. Times and Gaz.*, Dec. 18, 1880.

—

Peripheral Neuroganglioma.

Dr. AXEL KEY, of Stockholm, describes, in the *Hygeia* for 1879 (*Nordiskt Medecin. Arkiv*, Band xii.), the microscopic structure of a nerve-tumour removed from a journeyman tailor, aged 31, who was discharged cured after a stay of fourteen days in hospital. The tumour had commenced as a small knob in the soft parts in the neighbourhood of the left ala nasi, and had grown in the course of a year to the size of a plum. The extirpated tumour was encapsuled; it was not adherent either to the skin or to the subjacent bone; it was grayish-red in colour, homogeneous, and rather soft. After hardening in Müller's fluid, it appeared to be of tolerably firm consistence; it was sharply defined, with smooth round projections, and was of somewhat irregular flattened shape. To one of the projections were attached some shreds, like connective tissue. Macroscopically, it was like a sarcoma, and had been diagnosed as such in the hospital. The microscope, however, revealed an entirely different structure; namely, very large cells, which completely resembled ganglion-cells, and were inclosed in perfectly developed capsules, the interior of which had the same appearance as the capsules of ganglion-cells. The cells were apolar; and not only one, but two or three, or even more, were contained in the same capsule. In the shreds connected with the tumour was found a nerve broken up into fine fibres of unequal size, probably a portion of the infra-orbital. On examining these branches of nerve, it was clearly seen that the large ganglionic elements of the tumour were developed from the nerve-fibres. Thus there was in this case a true ganglioma, which throws light on the hitherto unsolved question, whether a tumour of this kind can be developed on a peripheral nerve. Only one case of ganglioma is described in

medical literature, viz., by Loretz in Virchow's *Archiv;* but the tumour, which was of the size of an egg, had proceeded from a pre-existing ganglion, and was thus a simple hyperplastic new growth. The case reported by Professor Key renders it certain that a ganglioma may be developed from a peripheral nerve, altogether independently of preceding ganglionic formations; and hence, in order to avoid all misunderstanding, Dr. Key calls this new growth, "neuroganglioma verum periphericum."—*British Med. Journ.*, Dec. 11, 1880.

The Plaster-of-Paris Jacket for the Treatment of Fracture of the Spine.

Sayre's jacket meets, as is well known, with a varying amount of approval in the hands of different surgeons. Those, however, who use it most frequently will, we believe, allow that its indiscriminate use will not lead to invariably satisfactory results; and not only so, but that some promising cases appear to go progressively from bad to worse notwithstanding the application of the jacket, while others in which its employment has seemed at first likely to be of doubtful utility have, contrary to expectation, been much benefited by it. We can call to mind two cases—one of a boy with an early condition of spinal caries in the dorsal region (just the case, it might be said, for the treatment), who, in six weeks after his jacket was put on, had a large psoas abscess; and another sickly child, with disease in the same part of the spine, and marked fulness in one iliac region, who, nearly a year after the plaster of Paris was applied, had a tolerably strong back, but in whom no abscess had shown itself. The use of this apparatus has long been suggested—and, we believe, practised—for fractured ribs, and from its employment for this purpose it is difficult to imagine any evil result following; but our German brothers have recently been using it for another object, in which, as might have been expected, a very varying amount of success has been attained.

In No. 7 of the *Centralblatt für Chirurgie* for this year is a paper by Professor König, of Göttingen, on the application of the "Thorax Gypsverband" for fractures of the spine, which recounts three cases, in all of which, although considerable displacement was present, very slight, if any, nervous symptoms had arisen. In each of these three instances the patients were suspended sufficiently to correct the deformity, and a long jacket reaching down to the trochanters was put on; and every one of them made a complete and rapid recovery. On the other hand, in No. 46 of the same journal we find a paper by Dr. W. Wagner, of Königshütte, which tells of two similar cases in which, after the application of the jacket, such intense pain in one instance, and paralysis in the other, set in, in the lower extremities, that it was necessary to remove the apparatus. In one it was re-applied later, with comfort to the patient. Both patients recovered. Professor König, after pointing out that all the cases treated by him in this way were recent and simple, adds that it is obvious that if extensive injury of the spinal cord is present, especially if the injury be of some standing, and bedsores have perhaps already developed themselves, it cannot be expected that the case will be benefited by the treatment; but, as he says, the diagnosis of the degree of injury is not, as a rule, a very difficult one. For uncomplicated cases the plan seems likely to prove of great service, and is undoubtedly an improvement on any of the older methods of treatment now in vogue; but the moment of suspension can scarcely fail to be one of anxiety to the surgeon, as it is easy to understand how the correction of a deformity may cause pressure on a cord which has previously escaped injury. This danger is very likely more hypothetical than real, and is probably exaggerated in our minds by the cautions that have been impressed upon us, as students, against attempting to rectify deformities so

produced—the practice of "letting sleeping dogs lie" having commended itself to our fathers as, on the whole, the safest.—*Med. Times and Gaz.*, Dec. 18, 1880.

—

Fracture of the Sacrum.

By its position and structure the sacrum is peculiarly free from liability to fracture except from bullet wounds, and, although it is sometimes found fissured, or even comminuted in severe crushes of the pelvis, simple uncomplicated fracture of this bone is a very rare accident. Erichsen has seen one such case, the injury being a blow from the buffer of a railway carriage, and proving rapidly fatal. Agnew says that simple transverse fracture of the sacrum is usually accompanied by fatal injuries to the pelvic viscera.

A remarkable case has recently been put on record in Paris. A woman, thirty-six years of age, was brought into the St. Lazare Hospital with the history of having fallen about eight feet on to her buttocks. She fainted, and when she was conscious was quite unable to sit. A slight transverse depression corresponding to the middle of the sacrum was readily felt from the back, the part was very tender, and pressure gave fine crepitus; extensive ecchymosis quickly occurred over the whole sacrum. From either the rectum or vagina the line of fracture was readily felt, and the projection forwards of the lower half of the sacrum verified, this part of the bone was easily moved with crepitus. Reduction was easily effected by the finger pressed back from the front, and displacement did not recur. A bandage was applied firmly round the pelvis and the patient kept in bed. Defecation gave intense pain, and the woman was unable to lie on her back for a fortnight, but sat up in bed on the twenty-eighth day, and got up in the ward on the forty-second day. There were no signs of pressure upon or other injury of the lower sacral or coccygeal nerves.

In cases where there has been a tendency for the displacement to recur, various mechanisms in the rectum have been employed to keep the bone in position, such as a plug of wood, a stuffed silver canula which could be opened to allow the passage of feces. The ease with which in the above case the reduction was effected shows that the displacement was due to the direction of the fracturing force, and not to the action of the muscles attached to the lower fragment. The main difficulty in the treatment of these cases where the fracture is the sole injury is the intense pain in defecation, and the local disturbance it induces. Some have, by means of opium, kept the bowels confined and then cleared the rectum by an enema every week or ten days. It is still better to diet the patient very carefully with a view to the production of the smallest possible quantity of feces, which may then be easily and almost painlessly removed by means of an enema every three or four days.—*Lancet*, November 20, 1880.

—

Tight Rings.

Treatises on operative surgery are absolutely silent on the constriction, by rings, of fingers swollen from one cause or another, and on the method of removing them. The accident is, nevertheless, of common occurrence, causes great pain, sometimes gives rise to great uneasiness, and may even threaten the safety of the finger itself. As a rule, in these cases of constriction, the ring is cut unnecessarily, for want of a simple method of removing it, notwithstanding the popular plan which comes to us by tradition, and is thus described by Oribasius, vol. iv. p. 251, Daremberg's edition. He writes: "Sometimes the finger is constricted by a ring; and it is necessary to remove the ring without delay, by giving it a rotatory motion; bathing at the same time the finger with warm water, and greasing it

with some kind of fatty matter. If the ring do not yield to these efforts, the following operation is recommended. A thick and twisted thread is sharpened at one end in the same way as cobblers sharpen their threads, and passed between the finger and the ring, whilst the rest of the thread is rolled round the finger. When this thread is unrolled, the ring moves towards the tip of the finger, whence it can be removed. If the ring resist this treatment, it is then necessary to cut it." Aetius, who lived at the end of the fifth and the beginning of the sixth centuries, repeats the recommendations of Oribasius. A writer in the *Concours Médical* suggests some improvements on the plan, so as to reduce the volume of the finger by ischæmiatizing it, in the same way as ischæmia is produced with Esmarch's bandage. In the first place, the finger is coated with fatty matter; then a thin thread, about a yard and a quarter long, is taken; one end is placed under the ring, and passed above it with a pair of pincers to the length of about three inches. The end of the thread being thus fixed by the ring, the rest of the thread is taken to the top of the finger, round which it is rolled in close overlapping lines, not leaving any space between them. This done, the second end of the thread is also passed under, and brought up above the ring. Then, this end being taken between the fingers, the rest of the thread is unrolled resting on the ring, which is thus gradually brought up to the point, where it is easily removed. If a first trial do not always succeed, it is rare for the ring not to yield to efforts twice or thrice repeated. Should this be the case, the ring, of course, must be cut on a canulated sound with a file or divider.—*British Med. Journal*, Dec. 18, 1880.

Midwifery and Gynæcology.

On Listerism in Gynecology and Midwifery.

FRANKENHAUSER (*Centralblatt f. Gynæk.*, No. 22, 1879) thinks that the principal agent in producing infection is impure air. He, therefore, performs all his operations under the spray, and limits the number of students at his ovariotomies to four or five, who take off all unnecessary articles of clothing before coming into the operating room. On the other hand, he looks on the prophylactic intrauterine injections *post partum* as carrying with them more danger than they avoid. If the hand has to be introduced into the genitals, it is always done under the spray, which is even used when making an ordinary examination, for he thinks it is much easier to prevent the entrance of impure air than to wash away septic material once it is formed.

When reporting Frankenhäuser's paper, Oeri says that for some years back, in Bischof's clinique, the spray is always used when the hand has to be introduced into the uterus, the perineum to be sewn up, as well as during many gynecological operations. Even during the time, however, when the antiseptic injections alone were made use of, it was usual to find patients recovering after protracted labours, manual removal of the placenta, or decomposition of the ovum, without any feverish symptoms.

In the report of the obstetrical clinique of Prof. WEBER RITTER von EBENHOF, in Prague, for the year ending Ap. 30, 1879 (*Centralblatt*, No. 26, 1879), a description is given of the precautions that are taken for avoiding septic infection during labour and the lying-in state. No student is allowed to make any examination who has any sort of sore on the hands, or whose nails are long or dirty. Even after the most thorough washing of the hands the students are

obliged, before making an examination, to rinse them first in a two per cent. solution of carbolic acid, and afterwards in a solution of permanganate of potash and weak hydrochloric acid. The finger is then covered with a five per cent. solution of carbolic acid in glycerine. As soon as a new patient is admitted her vagina is washed out with a two per cent. solution of carbolic acid, and the parts about the vulvæ thoroughly washed with soap and carbolic acid solution. If the labour be long delayed after the escape of the waters, the vagina is washed every two hours with carbolic acid solution. In order to prevent the entrance of air into the vagina a wad of cotton steeped in dilute liq. chlori. (1 to 8) is laid before the vulvæ. After the expulsion of the placenta the vagina is washed out by the head midwife with carbolic acid solution, and if the labour has been a protracted one, the fœtus decomposed, or any operation been undertaken, the assistant himself must wash out the uterus with a three per cent. carbolic acid solution. All fissures of the genitals are closed with carbolized catgut, and ruptured perinea with carbolized silk. If the vagina has been much bruised a wad of cotton-wool saturated with camphor is passed into it immediately after the removal of the placenta. In all natural labours the child is born under the hand-spray, and all operations are performed under the steam-spray. The placentæ, till removed from the ward, are placed in a solution of carbolic water. All dead children are at once removed, and closets for soiled linen are disinfected with chloride of lime. To prevent infection after labour the vagina is washed out every two or three hours with lukewarm two per cent. carbolic acid solution, which has previously been boiled. If fever is present a carbolic acid decoction of chamomile flowers of the same strength is used. All the old tin injection tubes have been replaced with glass ones. In all cases where the passage is injured or there are puerperal ulcers, a wad of cotton is laid before the vulva, impregnated with carbolic acid or camphor. The nurses are made to wash their hands in carbolic solution after having in any way come in contact with the genital tract of a lying-in woman. It is of great importance to treat the first indications of fever promptly by injections of three per cent. solution into the uterus, and the administration of purgatives. Nine mothers died out of 925 mothers thus treated, being a mortality of less than one per cent.

Of late years it has been proposed, with a view of lessening the chance of puerperal infection, to wash out the vagina, cervix, and uterus of every lying-in woman with a three per cent. solution of carbolic acid immediately after the child is born. HOFMEIER (*Centralblatt f. Gynaek.*, No. 5, 1880) found that of 260 cases treated thus prophylactically by him in the University Lying-in Hospital in Berlin, 16 per cent. were attacked with fever, 8 of them very severely, while of 249 patients not so treated only 8 per cent. got ill, only 1 case being serious. Hence he concludes that such treatment of ordinary cases does more harm than good.

It is very different, however, when we have symptoms of putrefaction or decomposition taking place during labour, accompanied by the formation of gas in the uterus and elevation of temperature in the patient. Stande found that 57 per cent. of such cases were attacked with fever, and that 50 per cent. died. It is evident, therefore, that we should endeavour to remove and render harmless every particle of decomposing matter, for which purpose it will be necessary to use a tolerably strong solution (at least five per cent.) of carbolic acid. Of 27 such cases, with temperatures reaching above 106° F. and pulses up to 144, that were thus treated *post partum*, 6 only died, or 22 per cent., and 18, or 60 per cent., made an uninterrupted recovery. The wonderful contrast between the threatened danger and the undisturbed convalescence can only be properly

appreciated by a perusal of the whole history of such cases which Hofmeier hopes shortly to publish.—*Dublin Journal of Medical Science*, Nov. 1880.

Absence of the Vagina; Uterus distended by retained Menstrual Fluid; Operation; Recovery.

At a late meeting of the Obstetrical Society of London (*Lancet*, Nov. 27, 1880), Dr. C. H. CARTER stated the case of a patient, aged sixteen, who had never menstruated. Pain had begun two years previously, and recurred almost daily. The urethral orifice was found large, the vagina absent. By rectal examination the finger felt the sound in the bladder with only a thin layer of tissue intervening. About one and a half to two inches up the rectum a rounded elastic mass was felt, reaching up half way to the umbilicus, about the size of the uterus at the third or fourth month of pregnancy. On July 25th the operation was performed for making an artificial vagina. After slight longitudinal and lateral incisions, the passage was chiefly torn by finger and director. Nothing like os or cervix uteri could be detected. The uterus was first punctured with the aspirator, and the opening then enlarged with a bistoury. About ten ounces of treacly matter escaped; several ounces of treacly fluid were afterwards expelled, and the same evening the dressings were soaked with fresh blood. The next day syringing out the uterus with carbolic lotion (1 in 80) was commenced. For about ten days there was some elevation of temperature, and a rapid pulse, 112 to 130, but the disturbance then passed off. When the patient went out on Oct. 11th, the new vagina had narrowed a good deal, and only admitted the finger for about three-quarters of an inch. Thick sounds were passed occasionally to keep open the passage into the uterus, and menstruation took place regularly after the operation. In October of the following year an examination was made, and it was found that the ordinary sound could not be passed into the uterus, but a small-pointed sound could be passed into it three inches and a half. The author expressed to the mother his opinion that marriage was inadmissible, since delivery could not take place *per vias naturales*.

Dr. GALABIN'S experience was, that the difficulty of keeping an artificial vagina in a condition fit for married life and parturition was considerable. He had had a similar case, in which also no trace of os or cervix could be detected. An artificial vagina was successfully made, and the patient afterwards menstruated naturally; but the attempt to keep the passage of full size was defeated by the fact that the pressure of the dilator repeatedly caused an opening into the bladder, though without producing any continued incontinence of urine.

Dr. ROUTH said that in his own case the patient had not died from the operation, but from the rupture of another cyst. He believed that in most of these cases the vagina had originally existed, but became subsequently adherent. He thought so in his own case, from the case with which he tore it open. He thought that the passage could be kept dilated by using sponge-tents, and subsequently Sim's dilators. The dilators should not be too large, and should not be worn more than a few hours at a time; they then would not cause inflammation. He mentioned a case in which Mr. Baker Brown had made a good artificial vagina, and the girl subsequently went upon the town and consorted with Life Guardsmen.

Dr. BRAITHWAITE said there were two classes of cases of atresia, one being incomplete, a fistulous track existing. From the presence of mucous membrane in this contraction was less likely. When the atresia was complete he thought that mucous membrane might be transplanted from the vulva or from an animal, to prevent the tendency to contraction. In a difficult case, the urethra might be dilated and the finger kept in the bladder, and the thumb in the rectum, during the operation.

Dr. GODSON said that he had that morning seen a young woman for whom he had reluctantly made an artificial vagina two months since. There was no retention of menses, but she had married in ignorance of her deformity. Though a fortnight ago there was a capacious canal, it would now barely admit a penholder. He believed that such failure was inevitable, and would not again operate unless there were retained menstrual discharge.

Dr. AVELING thought that Dr. Carter was quite right in dissuading his patient from marriage. He did not agree with Dr. Routh that the majority of cases of absence of vagina were due to inflammatory adhesion. In the three cases he had seen it was evidently congenital, as the uterus was also absent, though the ovaries were present.

Dr. CARTER, in reply, said that Dr. Emmet stated that the tendency to close depended upon the passage being made by cutting rather than by tearing. He did not think that the tendency to contract depended altogether upon the absence of mucous membrane, but rather upon the contractility of the tissues, since in his case a mucous membrane like that of the labia minora was noted in the new passage. He agreed with Dr. Galabin that it was better to defer washing out the uterine cavity a short time. He did not recommend marriage in his case, because the end of the new vagina was closely attached to the margins of the opening into the uterus No natural dilatation of this opening could occur in labour, and Cæsarean section would probably be necessary.

The Mechanical Dilatation of the Uterus.

FRITSCH thinks (*Die mechanische Uterus Dilatation, Centralblatt f. Gynaek.*, No. 25, 1879) that where our only object is to dilate the uterus we should entirely abandon such means as the sponge-tent, laminaria, or tupelo, in favour of rapid instrumental dilatation, by which we can so entirely avoid all risk of septic infection. He uses for this purpose graduated steel sounds, seemingly very similar to those proposed by Peaslee in 1870. The thickest is about the size of a thick finger; the smallest is somewhat larger than a thick sound (0.5 mm.). He first introduces one of the smaller sounds to the inner os, and then grasps the uterus externally, and presses the fundus down over the sound. This often requires an amount of force which would be quite unallowable if applied only from within, without the control of the hand externally. The danger of septic infection can certainly be avoided by using frequent injections, and it is much safer than the metrotome. He has made use of the method in multiparæ to remove retained portions of an abortion, mucous polypi, and to enable him to use the curette. As to its efficiency in cases of dilatation of the inner os he has no experience.

It is only when we wish to produce artificial infiltration of the uterus that the slow process is indicated. If we wish to strengthen a flabby uterus, to give tone to the circulation, or increase the power of contraction, then we should make use of the laminaria. If we only want to open the way into the uterus, then we should use rapid instrumental dilatation.

This paper has elicited one from Professor C. SCHROEDER, of Berlin ("Sind die Quellmittel in der gynaekologischen Praxis nothwendig?"—*Centralblatt f. Gynaekologie*, No. 26, 1879), in which he says that he does not think that in private practice he has made use of the slow method of dilating the uterus for more than one and a half years, and even in hospital it is now only rarely that he does so, and when he finds it necessary he uses the tupelo tent. Many years ago he procured a set of graduated sounds, such as Fritsch advises, but uses them only very rarely. Nor can he say that he has been led to abandon tents from finding their use too dangerous, for he thinks such accidents as have occurred

might be certainly avoided in the future by following Schultz's antiseptic method, which has, however, the disadvantage of most wearily lengthening the whole process. He has, however, been led to abandon them, partly because, in many cases where he formerly used dilatation for the purpose of diagnosis or treatment, he can now attain his object by means of the sharp scoop, which can be passed through the undilated os, and part or all of the mucous membrane of the uterus so removed. When, however, he requires to pass the finger into the uterus, he now first incises both sides of the cervix as far as the roof of the vagina on both sides, and then forces the finger into the cavity, either by pushing down the fundus from above, or drawing the cervix over the finger by means of a Museaux' vulsellum. In some cases it is quite surprising how readily this may be done; in difficult cases we will generally rupture some of the fibres of the inner os. These slight ruptures, if not infected, heal readily, and when we have finished our diagnosis or treatment we can close the cut sides of the cervix with sutures.

Though a very large number of cases come annually before him, he has in this way been led almost entirely to give up the use of tents for dilating purposes.

In the number of the same paper for April 24th of this year, Dr. FRANCK gives an account of the results obtained by using Prof. Schultz's dilator—the essential conditions for its use being that the cervical canal should measure at least 6 mm., and that there is no inflammatory process going on in either the uterus or its appendages. The instrument, after being thoroughly cleansed and disinfected, is passed into the uterus and the branches separated. The amount to which this is possible varies greatly with the condition of the uterine tissue and the varying amount of pain experienced by the patient. The instrument is then withdrawn to see what size the passage is, and before it is again introduced the uterus should be carefully washed out with warm water to prevent infection. With such precautions it is absolutely without danger, and it has the great advantage that it produces the same amount of dilatation in a few minutes that laminaria tents do in about eight hours. In cases where the woman has not borne a child, or where the cervix has not the diameter of 6 mm., it is necessary to begin with a single laminaria tent. He says the patient after the dilatation must remain lying for at least an hour, but need not necessarily be confined to bed. If the spasmodic pains still continue she should have an opium suppository and warm stupes to the abdomen. He thinks that this dilatation repeated at intervals has a powerful effect in curing subinvolution and flaccidity of the uterus. It also causes the expulsion of portions of retained placenta or membranes, and retroflexions may also be cured thereby, provided there are no adhesions present. Stenosis of the inner, but not of the outer, os will yield to this treatment.

In *The Lancet* for Nov. 1, 1879, Mr. LAWSON TAIT gives twelve cases in which he dilated the cervix by continuous elastic pressure. He says: "I have had such unsatisfactory results from all kinds of tents in dilating the cervix uteri that I have long desired to get something which would accomplish this more safely, more speedily, and with less pain. Having been struck by the ease with which an inverted uterus can be returned by continuous elastic pressure, I applied this method for the purpose of dilating the cervix, and my results have been so completely satisfactory that I hasten to narrate my experience of the first twelve cases in which I have used it." The advantages of the plan are that it is absolutely free from smell and septic risks, and almost free from pain. It produces more complete dilatation of the whole canal than that obtained with tents. The dilators are made of vulcanite, and are sold in sets of four sizes to screw into a common stem. "The only precaution necessary in their employment is to use

extremely gentle pressure." In this paper Mr. Tait does not, however, enter into any details as to how the continuous elastic pressure is to be applied.

Just as we were going to press we received one of the series of *Volkmann's Clinical Lectures*, by Dr. LEOPOLD LANDAU, on "The Various Methods of Dilating the Uterus" (*Ueber Erweiterungsmittel der Gebärmutter*), which treats the whole subject in a most exhaustive manner.—*Dublin Journal of Medical Sciences*, Nov. 1880.

—

On the Treatment of Ruptures of the Uterus.

Dr. FROMMEL, Assistant Physician to the Gynecological Clinique in Berlin, publishes two interesting cases of this accident in No. 18 *Centralblatt für Gynäkologie*, 1880. Case I. refers to a patient 40 years old, who had given birth twelve times previously, and who suffered from slight contraction of the pelvis—diagonal conjugate being 4 inches. The labour had been a prolonged one, and had suddenly become arrested, when the assistance of Dr. Hoffmeier was obtained. He removed without great difficulty, by version, a dead full-grown child, and discovered an almost complete tranverse rupture of the uterus between the lower segment and the cervix, only a bridge of tissue about 2½ inches broad to the left and anteriorly remaining to connect the two. The peritoneal investment of the uterus was quite entire; but as the child had passed out through the rent in the uterine tissue, it was almost completely separated from the uterus, so that now a large cavity shut off from the peritoneal cavity existed. Dr. Hoffmeier caused the patient to be immediately brought to the hospital, in which a thorough irrigation of the cavity with a warm two per cent. solution of carbolic acid was performed under chloroform, and a thick drainage tube introduced through the vagina into the cavity. This was secured in position. An ice bladder was put upon the abdomen. The condition of the patient was after this satisfactory. No vomiting; pulse strong, regular, 84. The highest temperature which she reached was 100° on the evening of the sixth day. This was also the only time that an antiseptic injection was made through the drainage-tube. For the first few days the patient got only a little fluid nourishment. From the eighth day gradually more nourishing food was administered. During the first days a tolerably copious bloody fluid was discharged from the drainage-tube, which after a few days became less bloody, and, finally, purely pus. On the twenty-sixth day, no further discharge appearing, the drainage-tube was taken out. On the twenty-eighth day the patient was allowed to rise, and on the thirtieth day she was discharged. On internal examination an opening several centimetres deep was found to exist anteriorly to which the finger could penetrate up to the peritoneum. On the right there was a considerable amount of exudation; the uterus somewhat dislocated towards the left and retroflected. General condition good. The second case was that of a patient 30 years old, who had suffered from rickets in early life, and had three times been delivered naturally. In her fourth confinement, in consequence of the labour proving tedious, the midwife administered four powders of ergot. A medical man who was called prescribed morphia, and, having obtained the aid of another medical friend, diagnosed rupture of the uterus, for which laparotomy was decided upon. The execution of this operation was prevented by the opposition of a drunken husband, whereupon the patient was taken to the hospital. On examination under chloroform the parts of the child were to be felt directly under the abdominal wall. Internal examination discovered the child situated with its head presenting, quite movable, at the pelvic brim, the whole child and placenta having passed into the abdominal cavity. The body of the uterus was almost entirely torn from the lower segment and cervix, except for

a small connecting part on the posterior wall, and lay powerfully contracted, pushed upwards and backwards. Professor Schroeder delivered at once, by version and extraction, a fresh, full-grown female child, whereupon the abdominal cavity was washed out with two per cent. carbolic acid, and a thick drainage-tube introduced as high as possible into the peritoneal cavity, which was secured likewise by suture to the posterior commissure. On the abdomen a bandage was so applied that the uterus was pressed firmly backwards and downwards, and also the cavity compressed. Thereby a great accumulation of blood in the abdominal cavity was prevented. In addition an ice-bladder was put on the abdomen. The condition of patient thereafter was wonderfully good. The pulse was somewhat frequent and irregular, but powerful; the temperature not elevated. This case also ran a favourable course. During the earlier days a copious bloody fluid was discharged through the tube, which became purulent after ten or twelve days. The temperature only once rose to 101°. As often as it exceeded 100°, which it did on several evenings, a two per cent. carbolic solution was injected into the cavity through the drainage-tube, which readily flowed out past the tube. For the first few days attempts were made, by the administration of opium, to prevent peristaltic action of the bowels, so as to allow the formation of adhesions around the torn part. The pulse, which from the first was frequent, ultimately settled down to about 100, but was strong and regular. On the seventeenth day after delivery the drainage-tube was removed, when the opening was found only large enough to hold the tube, and secreted a small quantity of laudable pus. On the nineteenth day the patient got up, felt well, and complained of nothing. Two days afterwards she was discharged. To the account of these interesting cases the author adds a few words in recommendation of the practice.—*Edinburgh Med. Journal*, Nov. 1880.

—

Hyperpyrexia after Listerian Ovariotomy.

At a late meeting of the Royal Medical and Chirurgical Society, Dr. BANTOCK read a paper on this subject which elicited one of the most animated debates upon Listerism which has yet occurred in London. Dr. Bantock stated that Mr. Lawson Tait had already questioned, before the Society, the advantages attributed to the Listerian precautions in the operation of ovariotomy. The absence of pyrexia has been claimed as one of the best results following such precautions. In this paper the fact that pyrexia is absent in cases treated antiseptically is disputed on clinical evidence. In the author's own experience, the Listerian method in a series of thirty-six cases shows in its favour a difference of but 0.4°, compared with the same number of cases undertaken without complete antiseptic precautions; the very lowest temperature occurred after a non-Listerian ovariotomy. Volkmann admits a condition of poisoning from absorption of carbolic acid, and terms this accident "aseptic fever." Thiersch has encountered instances of great irritation from this agent, and now employs salicylic acid in its stead. Keith finds very little difference in the temperature of series of cases undertaken under the old and the new method. In three Listerian cases the temperatures were the highest he had ever seen. Before adopting antiseptics he never found the ice-cap necessary for the reduction of pyrexia, excepting in one acute case of septicæmia. On the other hand, Mr. MacCormac asserts that the rise of temperature in Listerian cases is slight or absent, and when present is due to other causes; Mr. Spencer Wells has found that, contrary to Mr. Tait's experience, pyrexia is subdued by antiseptics. Mr. Thornton has observed no fever at all, as a rule, after antiseptic ovariotomy. When, however, an operator is disposed to support Listerism, he may readily attribute to other influences ill

results, of which it alone can be the cause. It is easy to explain how pyrexia follows "antiseptic operations." Carbolic acid is an irritant; its great advocate introduced the "protective" to counteract its irritating qualities. It is also a poison. It has caused death when inhaled, and has produced very serious symptoms when absorbed; this is illustrated in cases related by Lister, Lightfoot, Hanhorst, and the author, who describes at length two cases of poisoning from prolonged action of carbolic spray in complicated ovariotomies. In both, the kidneys were affected by this medium. Agostini relates a case of poisoning from carbolic acid solution injected frequently into an abscess cavity. Thomas Smith and others have noted the bad effects of this acid in operations upon children. The author observed albuminuria and temporary suppression of excretion of sulphates in the urine of a young girl after antiseptic ovariotomy. Sonnenburg, Lightfoot, and others have also found that sulphates disappeared from the urine in similar cases, whereas in the author's patient that excretion did not become dark. Hence carbolic poisoning is not always indicated and exposed by discoloration of the urine, as is generally believed. Keith admits that evil effects may result from prolonged action of spray. The hyperpyrexia which follows is due not solely to reaction, but also to carbolic intoxication. The whole merit of Listerism lies, not in the supposed good effects of carbolic acid, but in the cleanliness which it promotes. By greatly reducing the strength of the solutions used in operations, the author has gained excellent results with absence of pyrexia.

Mr. ERICHSEN remarked upon the local anæsthetic effect produced by the carbolic spray. It produced a numbness of the hands, and he thought this showed that the carbolic action had some action on the peripheral nerves.

Mr. KNOWSLEY THORNTON said, that no one had claimed that Listerism was never followed by pyrexia, unless it were Mr. Tait himself, who, in his paper published in the recent volume of the Transactions, says (page 133): "As the temperature and pulse-curve are uniformly admitted to represent the course of any case involving febrile action, if the antiseptic system makes its claims justly, ovariotomies performed under its precautions ought to indicate a more even and less febrile course of recovery than the non-antiseptic cases, and this should occur independently of all other details of the operation." Obviously more fever must follow a difficult operation than a simple one. In the debate on that paper Mr. Holmes remarked that the whole question was one of "impressions," and he (Mr. Thornton) resolved now to state facts; and to contrast the temperatures of non-antiseptic and antiseptic ovariotomy. Of the former he had had twenty-five successful cases with an average stay in hospital after operation of 26.3 days, and of the latter 150 successful cases with an average stay of 20.5 days. In twenty-five non-antiseptic cases the ice-water cap was used seventeen times, or in 68 per cent.; in 150 antiseptic it was used thirty-one times, or 20 per cent. It was used to reduce temperature in twelve non-antiseptic cases, or 48 per cent., and in fourteen antiseptic cases, or 9 per cent. On this point he saw from a letter from Dr. Bantock in the *Medical Times* that he agreed with him. In the remaining cases the cap was put on to prevent high temperature—viz., 20 per cent. of the non-antiseptic cases, and in 11 per cent. of the antiseptic cases; but of late he had limited its use to the reduction of temperature only. In the non-antiseptic series the temperature never rose above 100.4°—*i. e.*, there was no fever in but two cases, or 8 per cent., in the antiseptic—forty-five cases, or 30 per cent.; and if the cases in which there was a slight additional rise of 1° or 2° for a few hours be included, the figures would be 32 per cent. of the non-antiseptic series, as against 75 per cent. of the antiseptic recovering without fever. Dr. Bantock should not have styled his cases as Listerian ovariotomies at all, and the number (thirty-six) was too small to draw such large inferences as he

had done. Although he himself had practised antiseptic ovariotomy in 200 cases, he felt he had yet much to learn in the application of the method, and he generally found that when a case went wrong some detail had been omitted. In his last 100 cases, with a mortality of 7 per cent., three patients died from septicæmia, a result which he was sure would not have occurred had he thoroughly acted up to the theory of Listerism, and in Dr. Bantock's cases the drainage-tubes were often changed by the nurses during the night, a practice certainly *not* that of Listerism. Recently Dr. Bantock had (in *The Lancet*) published statements of practice which he styled Listerism, but which only proved that he was not in a position to carry out that practice, so contrary were they to Lister's express teaching.

The occurrence of nephritis could not be attributed to carbolic acid poisoning, for long before antiseptics were introduced into ovariotomy deaths occurred from suppression of urine, etc., and quite lately he had such a case, in which death took place within twenty-four hours after the removal of a tumour weighing 88 pounds, there being chronic Bright's disease. Septicæmia, too, was often fatal from failure of the kidneys to act, and comparison of the post-mortem records of such cases before the days of antiseptics showed no difference in the lesions observed in them and in those cases attributed to poisoning by carbolic acid. A German surgeon had recently said that in his country they had become so convinced that septicæmia had been banished by Listerism that deaths formerly attributed to this cause were put down to the toxic effects of carbolic acid. It was one thing to use the method and another to act up to Lister's practice and theory, and it would be far better if those who did not accept the theory would cease to practise the method, since their failures were no proof of the falsity of the theory. When studying under Professor Lister, at Edinburgh, he had repeatedly seen the urine darkened by carbolic acid without any other effects. He failed to see on what principle Dr. Bantock used a 1 per cent. solution of the acid, which Dr. Bantock said was no longer germicide. If so, why trouble to introduce this 1 per cent. of an "irritant" and a "poison?" Was it done to increase the cleanliness of the water? Dr. Bantock's results at the Samaritan Hospital were the same as those obtained by Mr. Spencer Wells without antiseptics at all, and using chiefly the extra-peritoneal method.

Mr. TAIT says that the advantages claimed for Listerism are really due to the adoption of intra-peritoneal method. But was this so? He had compared the statistics of the Samaritan Hospital for periods of six years with this result. Mr. Spencer Wells, from 1872 to 1877 inclusive, had 191 cases (extra-peritoneal) with a mortality of 20 per cent.; Dr. Bantock, from 1875 to 1880, inclusive, had 136 cases (intra-peritoneal and modified antiseptics) with a mortality of 17.64 per cent. Mr. Thorton in the same period had 181 cases (intra-peritoneal and antiseptics), with a mortality of 11.6 per cent. These differences were due to the more thorough use of the antiseptic method. In the present year, Dr. Bantock, using his *very modified* antiseptic method had had forty cases with a mortality of 12 per cent.; Mr. Thornton with pure Listerism, had fifty-four cases with a mortality of 7.4 per cent., including two deaths from septicæmia, which he attributed to failure in carrying out the method. Still, Mr. Wells in the last two years of his hospital practice had only a mortality of 10 per cent. in intra-peritoneal cases, a result largely due to the use of the ice-cap and drainage. In his own last 100 cases, Mr. Thornton had a mortality of 7 per cent., twenty-seven of these being private cases, with one death—a case of unusual difficulty. All this went to prove that with every case the mortality without Listerism could not get below 10 per cent.; and if by the adoption of the method the mortality

could be lowered by three or four per cent., that end was alone worth the extra trouble and difficulty entailed by the method.

Mr. Lawson Tait was surprised that Mr. Thornton should have quoted the passage from his paper in the sense he did, and regretted that there did not seem to be a clear understanding as to the meaning of Listerism; since it had just been stated that it was no part of the Listerian theory to avert septic fever. Hitherto he had thought that the whole aim of the theory was to eliminate this surgical fever after operations. If this were not its aim, what was it? In fatal cases of ovariotomy the temperature rises steadily to the end. He could not then concur in any of Mr. Thorton's remarks. As to the duration of stay in hospital, there was a great difference between cases in which the clamp was used and those in which it was not.

Mr. Thornton said he had excluded all clamp cases from this reckoning.

Mr. Tait, proceeding, said that he had a series of 137 abdominal sections, in which 48 were done with *extreme* Listerian precautions, and the remainder successively by the elimination, one after another, of these precautions; so that after reducing the strength of the carbolic spray to 1 in 150. he had finally conducted the whole of the process under a spray of water alone! And so far as the temperature went, it had diminished in proportion as the amount of carbolic acid was lowered. In the 48 pure Listerian cases there were 5 deaths; in the 91 "modified" cases, 6 deaths; and he did not know if any better result could be obtained than that. With Listerian precautions the wounds never heal by first intention, but always with formation of pus; and Dr. Savage who practises Listerism, remarked that in his cases the wounds did not heal so well as Mr. Tait's without it. Mr. Tait had had one case in a young woman, from whom he had removed both ovaries—no adhesions—in which the temperature rose to 112°, and remained at that height for forty-eight hours. She recovered perfectly, and there was nothing in the case but carbolic acid poisoning to account for the remarkable rise in temperature. The ice-cap could not be cited as a criterion; he himself had never used it. He once used Dr. Richardson's "collar," invented many years ago; but the case proved fatal, and he never used it again. Success depended more on personal care and experience than on anything else. Mr. Thornton had had the great advantage of being associated for many years with Mr. Spencer Wells, and this must be taken into account in comparing his statistics with those of others. He (Mr. Tait) lost nineteen out of his first fifty cases, and he did not think he would have had such a mortality had he had the opportunity of seeing, and assisting at, the operations of so distinguished a master.

Mr. DORAN having examined after death forty-one cases of ovariotomy, found that the kidneys were normal in only seven, and in one of that number death, was due to tetanus, in another to pleurisy. Of the renal disease six were cases of dilatation of ureter and pelvis on one side. The rest exhibited various degrees of subacute and chronic Bright's disease. In many cases there were lesions of other viscera, mostly diagnosed before operation; but the renal disease was nearly always latent; and this fact should be borne in mind before pronouncing on the statistical results of operations by different methods; and until it became possible to ascertain the existence of such disease there must always be room for fallacy in the comparison of such statistics. Albuminuria alone would not contra-indicate operation, for it might be due to pressure, which the operation would relieve. Diminution in the quantity of urea might be due to diminished quantity of food: and sometimes in renal disease there was an excess of urea. Dr. Bantock had remarked upon the diminution of the sulphates as evidence of carbolic acid poisoning. Dr. Parkes has shown that thirty-one grains of sulphuric acid are eliminated by the kidneys in twenty-four hours. After a severe operation

the call on the kidneys must be very great, and if they be diseased great risk was added to the patient's chances of recovery.

Mr. SAVORY said that the only point on which there seemed to be agreement, was that as experience increased the mortality diminished. He asked if this did not point to the question being one of the man rather than the method; and did not such a reflection vitiate all conclusions derived from statistics of the first twenty cases compared with the second twenty, and so on?

Mr. SPENCER WELLS would meet Mr. Savory's argument by the experience of the same surgeon in a successive series of years. No doubt the mortality diminished with increasing experience, but after a time the mortality reaches a level below which it will not fall, until the introduction of a new method leads to further improvement in the results. It had so happened with him. At first the mortality gradually fell from 34 per cent. to 28, to 24, and so on, until it reached a level beyond which it did not fall, and the question came whether it was possible to reduce the mortality still lower. This caused him to adopt the antiseptic treatment, and at the beginning of 1878 he commenced to follow Listerian methods. To be sure, the cases in which he applied it were all in private patients, but he had when in hospital practice found no difference in the results of the two classes of patients; nor was it due to the intra-peritoneal method, for before he used antiseptics he had been less successful with this than with the extra-peritoneal. Since adopting Listerism he had had 131 cases, with 13 deaths—a mortality of 10 per cent.; which was precisely the same mortality he had in the last two years of his hospital practice—viz., 7 deaths in 71 cases. These figures alone might be quoted to show there was no advantage gained by Listerism. But there were very real advantages. He was surprised to hear Dr. Bantock, Mr. Tait, and Mr. Thornton find such rises in temperature after Listerian ovariotomies, for he never saw them; it was rare to see the temperature over 100°. The method did not involve trouble—it greatly saved it. Formerly a case had to be closely and personally supervised; but all this trouble and anxiety were saved in treating a case antiseptically. Again, in forty-nine cases out of fifty so treated the wounds heal by first intention; and it was quite a matter of surprise to him to find, as he did lately in a case, any pus in the wound. In that case its appearance was explained by development of boils in other parts of the body. In reply to Mr. Tait, Mr. Wells added that when the pedicle was short he used the ligature in preference to the clamp.

Mr. HOLMES said that after all they had heard that evening from the advocates and opponents of Listerism he was ready to withdraw his former observation that the grounds urged in favour of the method were based only on "impressions"; and he would like to put it to the Society, whether, after these definite details, there were such characteristic differences between cases treated with and without the method, as would be the case were its theory true. Recalling the claims urged for the theory when it was first promulgated, he would ask whether it was at that time thought that 130 cases treated under the theory would show the same result as those treated otherwise? Whether, if one was not told, one would perceive any real essential difference between the cases which were treated on the basis of the germ theory and those without this basis? He was not a partisan of any one method. He had sat at the feet of Lister, and had tried to master the details of his method, which in the early days were far simpler than at present, for they had been so modified that he confessed he did not understand them, and he was sure Mr. Thornton did not understand them, since he attributes his fatal cases to a lack of mastery of these details. Did Mr. Lister himself even understand them? Was the theory itself understandable? When a case is lost, the failure is put down to failure to understand the theory; when a case is

saved, then the theory is triumphant. If this were all it came to, and after the method had been so long in use there was still a quarrel as to its advantage in 1 per cent. of the cases, it might fairly be said that the theory was "not proven."

Dr. BANTOCK, in reply, said that the local anæsthesia produced by carbolic acid was well known to him. He quoted from a paper written by Mr. Thornton to show that that gentleman attributed two deaths from pleurisy to the chilling produced by the spray, and one from suppression of urine to the carbolic acid: and in another paper spoke of extreme congestion of the kidneys as due to carbolic acid. In his own practice he had treated thirty-six cases with true Listerian precautions, with eight deaths, one patient dying on the operating table. With a solution of carbolic acid, 1 in 50, he had treated forty-one cases with a mortality of three; one of these cases was *in extremis* when operated on; another died from acute nephritis, and a third from tetanus, on the eighth day, and apparently independently of the operation. In two of these cases he had used the ice-cap, and he found that in proportion as the strength of the solution was reduced to 1 in 60, 1 in 80, to 1 in 100, the results improved, the ice-cap never being required since he had used the weaker solution. He had had many cases in which there was disease of the kidneys—a most unfavourable condition, owing to the little or no power of elimination. He quoted recent statistics of an Italian surgeon, showing that in his practice ovariotomy with Listerism in 100 cases gave a mortality of 37 per cent., and in a second series of 100 cases without Listerism a mortality of 36 per cent. Mr. Bryant had recently published facts showing that pyrexia in surgical cases was considerably less than supposed, without undue antiseptic precautions being taken. Mr. Spencer Wells had stated in his book that he never used the ligature when the clamp could be used, and it was not therefore surprising that the ligature should compare unfavourably with the clamp. The merit of using a solution of carbolic acid of 1 per cent. strength lay in its not causing hyperpyrexia; he had not once to use the ice-cap in cases treated with this solution, and out of twenty-nine cases had lost eight, two deaths being from shock. The great point was strict attention to cleanliness, and in this respect the modern practice differed from that formerly in vogue. Mr. Heath was the first to put this principle into practice, and combined with free drainage, found that Listerism did not add to the measures, although it added to the risk of subsequent pyrexia. The dread of injuring the peritoneum had disappeared before Listerism was taught, for it was shown that fever decreased in proportion as effectual drainage was practised, and the causes of irritation of the peritoneum avoided. Patients still died even under the strictest Listerism. He would not follow Galezowski, who said that since he had used antiseptics (!)—viz., solution of carbolic acid of 1 in 1000—his operations on the eye were markedly successful; and, whilst according full measure of praise to Mr. Lister's teaching, he could not admit the truth of those exaggerated pretensions claimed for his method by his disciples with a zeal which outran discretion.—*Lancet*, Dec. 18, 1880.

Medical Jurisprudence and Toxicology.

The Law of Slander as Applicable to Physicians.

The importance of a clear understanding of this subject to the practising physician is so great that we feel justified in reproducing, from the *American Law Register* (August, 1880), the following paper on the subject from the pen of Mr. W. H. WHITAKER, of Cincinnati:—

There is, perhaps, no class of professional men more subject to abuse, and, it is believed, more powerless to obtain redress, than physicians. About clergymen the law has thrown its protecting arm, and public opinion has been wont to overlook, if not to pardon, their short-comings. The clergyman is a sort of privileged person, whose character is tried before and whose conduct is regulated by ecclesiastical tribunals to which the courts of law have relegated it. Lawyers can take care of themselves.

For alleged professional misconduct, incapacity, or ignorance, for rumored unskilful treatment of diseases, physicians who choose may have recourse to legal proceedings. But to cowhide the editor or sue the newspaper for the circulation of a libel, may be said in either case to be social suicide. The physician must grin and bear it. But if he braves public opinion and asserts his rights, if he endeavours to obtain satisfaction at law, the chances are, to say the least, uncertain. It is doubtful, as the law now stands, what charges of misconduct in a physician in a *single* instance are actionable. One court (*Camp* v. *Martin*, 23 Conn. 86) has held that words spoken of a physician, charging him *merely* with ignorance or misconduct in the treatment of a particular case, were not actionable *per se*. The words were, "If Dr. C. had continued to treat her, she would have been in her grave before this time. His treatment of her was rascally."

Another court (*Secor* v. *Harris*, 18 Barb. 425) has adopted a contrary view in a similar case, where the words were: "Dr. S. killed my children. He gave them teaspoon doses of calomel: it killed them; they died right off, the same day." This last is no doubt a more aggravated case, but it is difficult to understand the grounds upon which the principle was distinguished in the two cases. The court said in the last instance that in the rendition of its judgment it was borne out by the authorities, while in the first case the court was equally confident, after having examined the authorities, that none could be found analogous to the case at bar, to justify an action for damages *per se*. Both, however, united on one case (*Sumner* v. *Utley*, 7 Conn. 257), as being in point, and it is amusing to observe what different constructions the two opposing tribunals gave to a case which must certainly have decided one way or the other. The Connecticut court said it thought that the case referred to, so far from varying the rule as they had given it, intended to sanction it, and quoted at length from C. J. HOSMER, as follows: "I readily admit that falsehood may be spoken of a physician's practice in a particular case, ascribing to him only such want of information and good management as is compatible with general knowledge and skill in his profession, and that when such a case arises, unless some special damage exists, his character will be considered as unhurt and no damages will be presumed. But, on the other hand, it is indisputable that a calumnious report in a particular case may imply gross ignorance and unskilfulness, and do him irreparable damage. A physician may mistake the symptoms of a patient, or may misjudge as to the nature of his disease and even as to the power of the medicine, and yet his error may be of that pardonable kind that will do him no essential prejudice, because it is rather a proof of human imperfection than of culpable ignorance or unskilfulness. On the contrary, a single act of his may evidence gross ignorance and such a deficiency of skill as will not fail to injure his reputation and deprive him of general confidence."

Now the New York court, on the other hand, said that the doctrine laid down in the cases of *Poe* v. *Mondford*, Cro. Eliz. 620, and *Foot* v. *Brown*, 8 Johns. 64, both of which were adopted as authorities by the Connecticut court, had been repudiated. In the former, defendant charged plaintiff with having killed a patient with physic, and it was held that the words were not actionable *per se*, and that the law only gave an action for words affecting a man's credit in his

profession, as charging him with ignorance or want of skill in general. In the latter the words were spoken of an attorney: "F. knows nothing about the suit, he will lead you on until he has undone you;" and it was held, on the authority of the former, that, no special damage being shown, the action would not lie. Rejecting these two cases as unauthoritative, the New York court also quoted from the case of *Sumner* v. *Utley*, *supra*, as follows: "As a general principle it can never be admitted that the practice of a physician in a particular case may be calumniated with impunity unless special damage is shown. By confining the slander to particulars, a man may thus be ruined in detail. A calumniator might follow the track of the plaintiff and begin by falsely ascribing to the physician the killing of three persons by mismanagement, and then the mistaking of an artery for a vein, and thus might proceed to misrepresent every single case of his practice until his reputation should be blasted beyond remedy. Instead of murdering character by one stroke, the victim would be successively cut in pieces, and the only difference would be in the manner of effecting the same result."

It is good to beat your adversary with his own weapons, and while the case of *Sumner* v. *Utley*, decided in effect that slanderous words spoken of a physician were actionable *per se*, the court in *Camp* v. *Martin*, *supra*, notwithstanding, drew a favourable conclusion for holding that in its case slanderous words were *not* actionable *per se*. It is true that the case of *Sumner* v. *Utley* was somewhat stronger than either of the other two, and may have furnished grounds for the distinction that was drawn between gross ignorance in a single instance, and gross ignorance generally in the treatment of diseases, but there seems to us to be little, if any, difference between a case where the words were that a doctor killed his patient, and one where they alleged that if he had continued to treat the patient she would have been dead by this time, so far as the presumption of incapacity is concerned. In *Sumner* v. *Utley* the words imputed gross ignorance generally and particularly. The defendant said of the physician: "He has killed three and ought to be hung—damn him. They all died through his mismanagement. I have understood that he left an after-birth, and the man that would do that ought to be hung;" and on another occasion, addressing himself to Mrs. H., who had employed plaintiff as her physician, said: "He was the means of her sickness by cutting an artery in her head—damn him; you ought not to pay him a cent; if Mr. H. had taken him up for it, it would have cost him $400. It ought to be put in the newspapers." The rule may be said to be as Chief Justice Hosmer put it, though it does not appear to be very clear: "This then is the correct principle, that the misrepresentation of a physician's practice in a particular case, if it does not warrant the presumption of damage is not actionable, unless special damages are averred and proved; but if from the nature of the calumny damages are inferable, the words are actionable."

The question still remains, when do the misrepresentations of a physician's practice in a particular case warrant the presumption of damage? It is allowed that slanderous words alleging gross ignorance generally, or such ignorance or thorough incapacity as unfits him for the proper exercise of his profession, are actionable *per se*. To say of a physician that "He is a quack" (*Pickford* v. *Gutch*, Dorchester Assizes, 1787); or "He is an empiric and a mountebank" (Vin. Abr. Act. for Words, S. a. 12); or "He is a quack; if he shows you a diploma it is a forgery" (*Moises* v. *Thornton*, 8 Term Rep. 303); or "He is no doctor; he bought his diploma for $50" (*Bergold* v. *Puchta*, 2 Thomp. & C. (N. Y.) 532); or "He is a drunken fool and an ass, and never was a scholar" (*Cawdry* v. *Tetley*, Godb. 441); or "He has killed six children in one year" (*Carroll* v. *White*, 33 Barb. 615); or "It is a world of blood that he has to answer for in this town through his ignorance. He was the death of J. P. He

killed his patient with physic" (*Tutty* v. *Alewin*, 11 Mod. 221); or "I wonder you had him to attend you. Do you know him? He is not an apothecary; he has not passed any examination. He is a bad character; none of the medical men here will meet him. Several have died that he has attended to, and there have been inquests held upon them" (*Southee* v. *Denny*, 1 Ex. 196). In all these cases it has been held that damages are inferable without proof; but to say of a physician, "He is so steady drunk that he cannot get business any more" (1 Ohio, 83, n.); or "He is a two-penny bleeder" (*Foster* v. *Small*, 3 Whart. 138); or to charge an allopathic physician with having met homœopathists in consultation, and that in the opinion of the profession it was improper to do so and against etiquette, and, further, that in the opinion of the profession it was disgraceful to meet a homœopathic in consultation (*Clay* v. *Roberts*, 8 L. T. N. S. 397); or to charge him with adultery not necessarily touching him in his profession without showing that it was connected with his profession (*Ayre* v. *Craven*, 2 Ad. & E. 2), have been held not actionable *per se*.

While the authorities are generally agreed as to charges of gross ignorance or incapacity in the exercise of the duties of the physician, it is not easy to determine what words are actionable in themselves in special instances. In analogous, and even in precisely similar, cases, the courts are divided. Where the words were: "He killed my child; it was the saline injection that did it" (*Edsall* v. *Russell*, 4 M. & G. 1090); or "He has killed my child by giving it too much calomel" (*Johnson* v. *Robertson*, 8 Porter, 486), they have been held actionable *per se*. And, on the contrary, the words, "He has killed his patient with physic" (*Poe* v. *Mondford*, *supra*), or "In my opinion, the bitters A fixed for B were the cause of his death" (*Jones* v. *Diver*, 22 Ind. 184), or "He gave my child too much mercury, or he made the medicines wrong through jealousy, because I would not allow him to use his own judgment" (*Edsall* v. *Russell*, *supra*), have been held not actionable in themselves.

In the examination of these cases, it will be found that where the physician is charged with killing his patient, the words have been held actionable on account of the imputation of crime which they import, and the only case in which such language has been held not actionable, is that of *Poe* v. *Mondford*, of an early origin. This case was rejected by the court in *Secor* v. *Harris*, on the ground that it was decided at a time when the doctrine of *mitior sensus* prevailed. And as for the case of *Jones* v. *Diver*, the court held that the words were not actionable, because they did not import a charge of murder; that if the defendant had said that "the bitters Dr. D. gave John Smith caused his death; there was enough poison in them to kill ten men," he would have been held guilty of the charge, and the words would have then been actionable.

How such words necessarily import the crime of murder or manslaughter, in the absence of any expression of intention, is not quite clear. This was not the ground of the decision in a case of a non-professional, charged with having destroyed the life of a patient by mistaken, but well-meant, efforts to save his life (*March* v. *Davison*, 9 Paige (N. Y.), 580). But even if the words do not import the charge of crime or of gross incapacity generally, there seems to be reason for holding that they should be actionable. It is true, as was said in a former case, that a physician might make a mistake in his treatment of a disease, because it was rather a proof of human imperfection than of culpable ignorance, but the consequences are often as fatal to him as though the charge was a general one. His mistake might be of "that pardonable kind" which would do him no injury in his profession, but the public might not pardon it. And what if he is not guilty of the charge? What if he has done his duty towards his patient, and has adopted every means in his power, and such as were recognized in the profession

as suitable for the case, to restore him to health? The consequences, so far as the public are concerned, are the same, with the additional mental suffering which every man must undergo whose conduct and whose actions are grossly misrepresented before the community at large. True, the law does not deny him his remedy, if he chooses to take it. Perhaps it would be more fatal to resort to legal proceedings in any case. If he does, he is compelled to show special damages, for none will be inferred. This alone would cause many to hesitate before bringing an action. The difficulty attendant upon proving damages, the length of time intervening between the publication and the consequences of a slander, would deter many from the prosecution of the slander.

As the cases now stand, you may bring almost any charge of misconduct against a physician in a particular case, without subjecting yourself to an action for damages *per se*, provided it does not come within the category of a statutory crime, or impute to him general incapacity.

On the Elimination of Lead by Iodide of Potassium.

At the instance of Prof. Vulpian, M. POUCHET has examined quantitatively the urine of patients suffering from saturnism, in order to estimate the effect of the administration of the iodide of potassium on the elimination of lead (*Archives de Physiologie Normale et Pathologique*, 1880). The methods were electrolytic. The quantities of urine examined always measured from five to ten pints, quantities sufficiently large to permit the detection of even the smallest traces of lead. During the period of aggravated symptoms, the urine contained an average of one milligramme of metallic lead to the litre of urine examined. Under the influence of iodide of potassium in doses of from four to six grammes daily, the elimination of lead increased quickly, but again decreased at the end of from six to ten days, when it became less marked than before the treatment was instituted. During the first days of treatment there occurred a rapid desaturation of the system, which was more or less decided according to the intensity of the morbid phenomena. Thus, in the case of a patient who was gravely affected, the quantity of lead passed by the urine, immediately after the administration of the iodide, rose to five milligrammes per litre. After the continuous administration of the salt for more than two weeks, the elimination of lead ceased almost altogether, so that in fifteen litres of urine only a trace of lead was discernible. But when, after withdrawing the remedy, the patient was allowed to rest some days, prior to the readministration of the iodide, small quantities of lead were again eliminated with the urine. Hence arises the therapeutic indication of employing the iodides for a long time, instituting, however, intervals of repose, during which the remedy is not to be administered. M. Pouchet also analyzed the urine of a patient treated exclusively with the bromide of potassium without detecting any increase of the lead eliminated. From this, he deduces the inefficiency of bromide in the treatment of lead-poisoning.—*London Med. Record*, Nov. 15, 1880.

MEDICAL NEWS.

Food Adulterations.

Some recent and valuable researches in regard to the intentional and accidental impurities in our various articles of diet, become especially interesting when we remember that a healthy adult male takes into his stomach during every year, on the average, about four hundred pounds of meat, five hundred pounds of bread, three hundred pounds of potatoes and other vegetables, ninety pounds of butter and fats, and one hundred and fifty gallons of tea, coffee, and water; because obviously in this large quantity of nutriment, impurities or adulterations to the extent of a single grain to the pound might eventuate in the introduction of an absolutely large amount of poisonous material into the human organism.

Foremost among these investigations are to be ranked those of Dr. Charles Smart, U. S. A., undertaken under the direction of the National Board of Health, and reported in the Supplement No. 11 of its valuable *Bulletin*. From a purely sanitary point of view, Dr. Smart's experiments are quite reassuring, since they demonstrate that with such exceptions as the use of alum in bread and baking powders, of sulphate of lime in the sophistication of creamor tartar, of water in the dilution of milk, and of the injurious colouring matters entering into certain kinds of confectionery, prevalent adulterations affect the pocket of the consumer rather than his health, and cannot therefore be characterized as deleterious, but only as fraudulent. Dr. Smart's conclusions are based upon the examination of 713 samples, of which 304 were obtained from sources (such as the proprietors of first class stores, who knew their goods were to be tested, from the Commissary-General of the Army, etc.) where their purity was probable, and 409 were specimens the origin of which might be considered suspicious. Of the former of these two groups about 8 per cent. were impure, whilst of the latter nearly 45 per cent. were so far sophisticated, that under a law similar to that enforced in Great Britain, for the punishment of fraudulent adulteration, the dealers from whom they were derived might have been prosecuted with a fair prospect of success. As pointed out, these percentages give us no exact idea of the prevalence of food adulteration, since of certain articles, such as lard and corn meal, which were found to be genuine, but few specimens were tested, whilst had the examinations of classes of articles such as the ground spices, which are seldom unadulterated, been more numerous, the proportion of impure articles of food in our markets would be represented as much greater.

In illustration of the details of these useful researches, it may be mentioned that 109 specimens of imported teas were examined, 90 of these being presumably pure and 19 from suspicious sources. In no case was any leaf met with which was not derived from the tea plant, and of the 90 samples in the first group all were approved, although 5 of the 19 from suspected origins were found to be so deteriorated that an analyst would be warranted in reporting them as fraudulently dealt with. The mixture of glucose with brown sugar appears to be not infrequent, as out of 38 samples purchased for examination, nine were adulterated with glucose, which, although not injurious, has an economic value inferior to that of cane sugar. As our author suggests, glucose properly prepared from starch, and sold under its own name, at the low rate for which it could be furnished, would be a great blessing to the poor, who now use large quantities of it, in the sophisticated cane sugar, for which they pay an unreasonable price. Creamor tartar, which is important in this connection, on account of its extended use in culinary processes, was found to be largely adulterated, only 6 out of 18 specimens examined being of satisfactory purity. Eleven of these samples contained sulphate of lime in quantities varying from 17 to 90 per cent., and two mixtures consisted of sulphate of lime and phosphate of lime, alum, and starch, without a trace of the tartaric acid salt. The results in regard to spices of various kinds were lamentably unfavourable; for example only 1 out of 26 samples of ground cinnamon was found to be pure, the adulterations in the remainder being powdered corn, wheat, beans, allspice, almond-shells, and turmeric; two out of 18 specimens of ground cayenne pepper, were met with of satisfactory purity, the only gratifying point respecting the 16 fraudulent mixtures, being that they contained no red lead, reported by Dr. Hassall some years ago, as occurring in nearly half the English red pepper. Mustard, which is even more important as a medicinal agent, was almost equally unreliable, only 6 out of 17 samples being honest in their character, the fraudulent admixtures being chiefly wheat flour, or starch, and turmeric, although corn starch, rice, cayenne pepper, and sulphate of lime were also used. Almost the sole really poisonous adulteration detected was that observed in the yellow coloured confectionery, which was found to be tinted in 3 out of 5 instances with pigment containing lead. In one of the remaining samples the yellow material was composed of antimony, and in the other of turmeric. These results confirm the more extended series of observations made by H. B. Hill of Harvard College, who reports that 19 out of 21 yellow, and 11 out of 12 orange candies, contained lead. Dr. Smart found that 13 specimens of red confectionery owed their tint to cochineal, and were therefore unobjectionable on the score of their colouring material.

Dr. Smart concludes, from his investigations, that food adulteration is now practised in this country to as great or even a greater extent than it

was in England when an effort was first made, some twenty-five years ago, to suppress this fraudulent and dangerous practice by stringent legal measures. The corn meal and lard we obtain, as well as our wheat flour, are pure, although bakers introduce alum into our bread. Sugars are less commonly sanded than formerly, but adulteration with glucose is becoming increasingly frequent. Thanks to our American fashion of grinding coffee at home, this important beverage may generally be secured pure, but our spices are very generally sophisticated, and some kinds of confectionery, especially those of a yellow or orange colour, are so apt to be poisonous that they should be studiously avoided.

The dangers to health arising from unsound and infected meat, such as of trichiniasis from diseased pork, and of phthisis from tuberculous beef and milk, etc., call for prompt and earnest consideration, which, however, must be reserved for some future occasion.

—

Listerism in Paris.—One of the most thorough disciples of Listerism in Paris—where the antiseptic method, slow to take root, is now the subject of an ardent and convinced propaganda—is M. Richelot, Professor *agrégé* of the Faculty of Paris. M. Richelot took the place of M. Richet at the Hôtel-Dieu, during a three months' holiday of the latter. The remarkable successes which he achieved were the subject of much observation, and produced a great impression on those who were able to contrast his results with the surrounding state of things. M. Richelot has published a *Note sur les resultats du pansement de Lister*, which is very interesting and satisfactory.—*British Med. Journal*, Nov. 27, 1880.

—

Deaths from Chloroform.—A writer in a recent number of the *Lancet* (November 6, 1880) states that during the past twelve months no less than twenty-five deaths from chloroform have been reported, and in comment says, "It is not for me to say that a grave responsibility rests on the surgeon who employs chloroform when a safer anæsthetic is available, but I think it cannot be long before the voice of the profession (if not of the public, as in America) demands some explanation for the use of an agent whose victims are numbered by hundreds."

—

Sheep's Tallow for Carbolic Acid Ointments.—HERR NUELCK, a Berlin apothecary, recommends, in the *Berliner Klinische Wochenschrift*, No. 30, the substitution of sheep's tallow for the ordinarily used oils as a menstruum for diluting and applying carbolic acid. Sheep's tallow has a much higher melting point than lard or oils; and thus remains as a soft, bland, and consistent salve, when the heat of the skin would melt the usual ointments, and convert them into flowing and irritating fluids. He gives formulæ for preparations and dressings made with carbolic sheep's tallow.—*British Med. Journal*, Dec. 18, 1880.

—

The Gross Surgical Prize.—The Philadelphia Academy of Surgery offers through its President, Dr. S. D. Gross, a Prize of Five Hundred Dollars for the best Essay on the Surgical Pathology, and Treatment of Tumours or Morbid Growths of the Testis, Scrotum, and Spermatic Cord, to be open exclusively to American Surgeons.

1. The Essay must be founded solely upon original investigations, be illustrated by suitable drawings, microscopical, and other, and be written in scholarly English.

2. The Essay must comprise an amount of matter equal to 250 pages octavo.

3. It shall be the property of the Academy, which shall, at its option, permit the author to publish it at his own risk or expense.

4. Each Essay must be accompanied by a motto, and by a sealed letter containing the author's name.

5. The award will be made at the meeting of the Academy in January, 1884, by a committee of five of its Fellows, consisting of D. Hayes Agnew, M.D., Wm. Hunt, M.D., R. J. Levis, M.D., John H. Packard, M.D., and J. Ewing Mears, M.D., Secretary, 1429 Walnut St., Phila.

Essays should be forwarded to the Secretary of the committee on or before October 15, 1883.

—

University of Pennsylvania.—Dr. William Pepper, Professor of Clinical Medicine, was, on the 12th ult., elected Provost of the University. The duties of the Provost were at the same time modified, and the supervisory and disciplinary functions of the Vice Provost and Deans of the various faculties were enlarged. We understand that the Trustees are desirous of having the University's needs actively brought to the attention of the public; and it is believed that Dr. Pepper's well-known energy and executive ability will largely conduce to this end.

Mr. Henry C. Gibson, of this city, with great liberality has offered the University Hospital to erect at his own expense a new wing for incurables, with accommodation for one hundred beds. The plans are now in preparation, and a permanent endowment fund for the support of the ward is being raised.

—

Bequest to Yale Medical College.—The late Dr. David P. Smith, Professor of Medicine in the Medical School of Yale, bequeathed his medical library, instruments, and two-fifths of his estate to Yale Medical College. The pecuniary bequest is for the endowment of the chair of Theory and Practice of Medicine.

—

Midwifery in Cincinnati.—It is stated that seventy per cent. of the labour cases in Cincinnati are delivered by midwives, who are for the most part ignorant and uneducated.

—

The Library of the College of Physicians of Philadelphia.—The annual report states that this library now contains 23,288 volumes, an increase of 1259 in the past year. We regret to learn that ill health has compelled Dr. Robert Bridges to resign the office of Librarian, which he has held for many years.

—

Library of the New York Academy of Medicine.—At the annual meeting of the Academy, in January, it was reported that the library contains over 17,000 volumes, and is in receipt of 122 current American and European medical journals. Mr. John Jacob Astor has recently given $500 for the improvement of the journal and circulating department of the library.

—

New York State Medical Society.—This Society will hold its annual meeting at Albany on the first day of February.

International Medical Congress, London, 1881.—The following subjects, in addition to those announced in our last number, have been proposed for discussion.

Section VIII. (*Mental Diseases*).—Anatomy: 1. Modes of Preparation of Nervous Tissues; 2. Morbid Appearances due to Modes of Preparation; 3. Minute Structure of Special Parts of Brain. Physiology: 1. Relation of Cerebral Localization to Mental Symptoms, as Hallucinations; 2. Hypnotism. Pathology: 1. Of Idiocy, Morphological and Histological Changes; 2. Relations of Insanity to Gout, Renal Disease, Exophthalmic Goître, and to Coarse Brain Disease. Clinical: 1. "Folie à Double Forme"; 2. Influence of Intercurrent Diseases on Insanity; 3. Insanity due to Toxic Agents. Therapeutical: 1. Use of Baths, of Narcotics, of Chloral Hydrate, of Opium, and of Alcohol; 2. New and Unusual Remedies. Asylum Administration: 1. Cottage and Village Treatment; 2. New Legal Codes—Austrian, Italian, English Projects. Civil Relations of the Insane: 1. Marriage, Wills; 2. Insanity and Aphasia. Criminal Relations of the Insane: Special Asylums for Insane Criminals.

Section XIV. (*Military Surgery and Medicine*).—1. By what arrangement can the practical difficulties in the way of employing antiseptic surgery (Listerism) in the treatment of wounds inflicted in the field in time of war be most readily overcome? [The discussion to include (*a*) the system on which the treatment can be most efficiently carried out; and (*b*) the fittest material means to be employed in it, under the circumstances in which armies are placed while on actual service.] 2. To what extent, and in what special directions, has conservative surgery advanced in field practice, as shown by statistical results of the treatment adopted for gunshot wounds during the wars of the last ten years? and what indications have been afforded, if any, by the experience gained during this period for making further advances in the conservative treatment of such injuries? 3. What are the most reliable, and at the same time practicable, means of immobilizing the parts involved in gunshot fractures of the Spine, Pelvis, and Femur in field practice? 4. On improvements in field hospital and transport equipment, for use with armies moving in uncivilized or partially civilized countries, suggested by the experience gained during the recent military operations by British troops in South Africa. 5. On the prevalence and prevention of Typhoid Fever among young soldiers in India.

—

International Exhibition of Hygiene.—It is proposed to hold during the International Medical Congress at London, an exhibition at South Kensington of sanitary and medical apparatus, under the auspices of the Executive Committee of the Parkes Museum of Hygiene. It is intended that the scope of the exhibition shall be broad, and all branches of sanitation will be included. In addition to sanitary apparatus there will be classes devoted to the exhibition of: 1, hospital construction and arrangement; 2, surgical instruments and apparatus; 3, appliances of the ward and sick-room; 4, drugs, disinfectants, and medical dietetic articles; 5, electrical and optical apparatus; 6, microscopes and other apparatus used in the investigation and relief of disease; 7, appliances used for the treatment of sick and wounded in time of war.

—

Allgemeine Wiener Medizinische Zeitung.—At the close of December, Dr. B. KRAUS celebrated the "twenty-five years jubilee" of this able journal, of which he has been the editor since its foundation. With the offer of our congratulations on the occasion we couple the hope that many years of prosperity and usefulness may await the journal and its learned editor.

their high professional standing.

I.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES,

EDITED BY I. MINIS HAYS, M.D.,

for more than half a century has maintained its position in the front rank of the medical literature of the world. Cordially supported by the profession of America, it circulates wherever the language is read, and is universally regarded as the national exponent of American medicine—a position to which it is entitled by the distinguished names from every section of the Union which are to be found among its collaborators.* It is issued quarterly, in January, April, July, and October, each number containing about three hundred octavo pages, appropriately illustrated wherever necessary. A large portion of this space is devoted to Original Communications, embracing papers from the most eminent members of the profession throughout the country.

Following this is the REVIEW DEPARTMENT, containing extended reviews by competent writers of prominent new works and topics of the day, together with numerous elaborate Analytical and Bibliographical Notices, giving a fairly complete survey of medical literature.

Then follows the QUARTERLY SUMMARY OF IMPROVEMENTS AND DISCOVERIES IN THE MEDICAL SCIENCES, classified and arranged under different heads, and furnishing a digest of medical progress, abroad and at home.

Thus during the year 1880 the "JOURNAL" contained 67 Original Communications, mostly elaborate in character, 170 Reviews and Bibliographical Notices, and 147 articles in the Quarterly Summaries, illustrated with 47 wood engravings.

That the efforts thus made to maintain the high reputation of the "JOURNAL" are successful, is shown by the position accorded to it in both America and Europe as the leading organ of medical progress:—

This is universally acknowledged as the leading American Journal, and has been conducted by Dr. Hays alone until 1869, when his son was associated with him. We quite agree with the critic, that this journal is second to none in the language, and cheerfully accord to it the first place, for nowhere shall we find more able and more impartial criticism, and nowhere such a repertory of able original articles. Indeed, now that the "British and Foreign Medico-Chirurgical Review" has terminated its career, the American Journal stands without a rival.—*London Med. Times and Gazette*, Nov. 24, 1877.

The best medical journal on the continent.—*Boston Med. and Surg. Journal*, April, 1879.

The present number of the American Journal is an exceedingly good one, and gives every promise of maintaining the well-earned reputation of the review. Our venerable contemporary has our best wishes, and we can only express the hope that it may continue its work with as much vigor and excellence for the next fifty years as it has exhibited in the past.—*London Lancet*, Nov. 24, 1877.

The Philadelphia Medical and Physical Journal issued its first number in 1820, and, after a brilliant career, was succeeded in 1827 by the American Journal of the Medical Sciences, a periodical of world-wide reputation; the ablest and one of the oldest periodicals in the world—a journal which has an unsullied record.—*Gross's History of American Med. Literature*, 1876.

The best medical journal ever published in Europe or America.—*Va. Med. Monthly*, May, 1879.

It is universally acknowledged to be the leading American medical journal, and, in our opinion, is second to none in the language.—*Boston Med. and Surg. Journal*, Oct. 1877.

This is the medical journal of our country to which the American physician abroad will point with the greatest satisfaction, as reflecting the state of medical culture in his country. For a great many years it has been the medium through which our ablest writers have made known their discoveries and observations.—*Address of L. P. Yandell, M.D., before International Med. Congress*, Sept. 1876.

And that it was specifically included in the award of a medal of merit to the Publishers in the Vienna Exhibition in 1873.

The subscription price of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" has never been raised during its long career. It is still FIVE DOLLARS per annum; and when paid for in advance, the subscriber receives in addition the "MEDICAL NEWS AND ABSTRACT," making in all nearly 2000 large octavo pages per annum, free of postage.

II.

THE MEDICAL NEWS AND ABSTRACT.

Thirty-eight years ago the "MEDICAL NEWS" was commenced as a monthly to convey to the subscribers of the "AMERICAN JOURNAL" the clinical instruction and

* Communications are invited from gentlemen in all parts of the country. Articles inserted by the Editor are liberally paid for by the publishers.

current information which could not be accommodated in the Quarterly. It consisted of sixteen pages of such matter, together with sixteen more known as the Library Department and devoted to the publishing of books. With the increased progress of science, however, this was found insufficient, and some years since another periodical, known as the "MONTHLY ABSTRACT," was started, and was furnished at a moderate price to subscribers to the "AMERICAN JOURNAL." These two monthlies have been consolidated, under the title of "THE MEDICAL NEWS AND ABSTRACT," and are furnished *free of charge* in connection with the "AMERICAN JOURNAL."

The "NEWS AND ABSTRACT" consists of 64 pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, by gentlemen of the highest reputation throughout the United States, together with a choice selection of foreign Lectures and Hospital Notes and Gleanings. Then follows the MONTHLY ABSTRACT, systematically arranged and classified, and presenting five or six hundred articles yearly; and each number concludes with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

As stated above, the subscription price to the "NEWS AND ABSTRACT" is Two Dollars and a Half per annum, invariably in advance, at which rate it ranks as one of the cheapest medical periodicals in the country. But it is also furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

In this effort to furnish so large an amount of practical information at a price so unprecedentedly low, and thus place it within the reach of every member of the profession, the publishers confidently anticipate the friendly aid of all who feel an interest in the dissemination of sound medical literature. They trust, especially, that the subscribers to the "AMERICAN MEDICAL JOURNAL," will call the attention of their acquaintances to the advantages thus offered, and that they will be sustained in the endeavor to permanently establish medical periodical literature on a footing of cheapness never heretofore attempted.

PREMIUM FOR OBTAINING NEW SUBSCRIBERS TO THE "JOURNAL."

Any gentleman who will remit the amount for two subscriptions for 1881, one of which at least must be for a *new subscriber*, will receive as a PREMIUM, free by mail, a copy of any one of the following recent works:—

"SEILER ON THE THROAT" (see p. 19),
"BARNES'S MANUAL OF MIDWIFERY" (see p. 25),
"TILBURY FOX'S EPITOME OF DISEASES OF THE SKIN," new edition (see p. 18),
"HOLDEN'S LANDMARKS, MEDICAL AND SURGICAL" (see p. 6),
"BROWNE ON THE USE OF THE OPHTHALMOSCOPE" (see p. 29),
"FLINT'S ESSAYS ON CONSERVATIVE MEDICINE" (see p. 15),
"STURGES'S CLINICAL MEDICINE" (see p. 15),
"SWAYNE'S OBSTETRIC APHORISMS," new edition (see p. 21),
"TANNER'S CLINICAL MANUAL" (see p. 5),
"WEST ON NERVOUS DISORDERS OF CHILDREN" (see p. 20).

*** Gentlemen desiring to avail themselves of the advantages thus offered will do well to forward their subscriptions at an early day, in order to insure the receipt of complete sets for the year 1881.

☞ The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" may be made at the risk of the publishers, by forwarding in REGISTERED letters. Address,

HENRY C. LEA'S SON & CO., Nos. 706 and 708 Sansom St., Phila., Pa.

DUNGLISON (*ROBLEY*), *M.D.*,

Late Professor of Institutes of Medicine in Jefferson Medical College, Philadelphia.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE: Containing a concise explanation of the various Subjects and Terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence, and Dentistry. Notices of Climate and of Mineral Waters; Formulæ for Officinal, Empirical, and Dietetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonymes; so as to constitute a French as well as English Medical Lexicon. A New Edition. Thoroughly Revised, and very greatly Modified and Augmented. By RICHARD J. DUNGLISON, M.D. In one very large and handsome royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, $7 50; half Russia, $8. (*Just Issued.*)

The object of the author from the outset has not been to make the work a mere lexicon or dictionary of terms, but to afford, under each, a condensed view of its various medical relations, and thus to render the work an epitome of the existing condition of medical science. Starting with this view, the immense demand which has existed for the work has enabled him, in repeated revisions, to augment its completeness and usefulness, until at length it has attained the position of a recognised and standard authority wherever the language is spoken.

Special pains have been taken in the preparation of the present edition to maintain this enviable reputation. During the ten years which have elapsed since the last revision, the additions to the nomenclature of the medical sciences have been greater than perhaps in any similar period of the past, and up to the time of his death the author laboured assiduously to incorporate everything requiring the attention of the student or practitioner. Since then the editor has been equally industrious, so that the additions to the vocabulary are more numerous than in any previous revision. Especial attention has been bestowed on the accentuation, which will be found marked on every word. The typographical arrangement has been much improved, rendering reference much more easy, and every care has been taken with the mechanical execution. The work has been printed on new type, small but exceedingly clear, with an enlarged page, so that the additions have been incorporated with an increase of but little over a hundred pages, and the volume now contains the matter of at least four ordinary octavos.

A book well known to our readers, and of which every American ought to be proud. When the learned author of the work passed away, probably all of us feared lest the book should not maintain its place in the advancing science whose terms it defines. Fortunately, Dr. Richard J. Dunglison, having assisted his father in the revision of several editions of the work, and having been, therefore, trained in the methods and imbued with the spirit of the book, has been able to edit it, not in the patchwork manner so dear to the heart of book editors, so repulsive to the taste of intelligent book readers, but to edit it as a work of the kind should be edited—to carry it on steadily, without jar or interruption, along the grooves of thought it has travelled during its lifetime. To show the magnitude of the task which Dr Dunglison has assumed and carried through, it is only necessary to state that more than six thousand new subjects have been added in the present edition.—*Phila. Med. Times*, Jan 3, 1874.

About the first book purchased by the medical student is the Medical Dictionary. The lexicon explanatory of technical terms is simply a *sine qua non*. In a science so extensive, and with such collaterals as medicine, it is as much a necessity also to the practising physician. To meet the wants of students and most physicians, the dictionary must be condensed while comprehensive, and practical while perspicacious. It was because Dunglison's met these indications that it became at once the dictionary of general use wherever medicine was studied in the English language. In no former revision have the alterations and additions been so great. More than six thousand new subjects and terms have been added. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference. We may safely confirm the hope ventured by the editor "that the work, which possesses for him a filial as well as an individual interest, will be found worthy a continuance of the position so long accorded to it as a standard authority."—*Cincinnati Clinic*, Jan. 10, 1874.

It has the rare merit that it certainly has no rival in the English language for accuracy and extent of references.—*London Medical Gazette*

As a standard work of reference, as one of the best, if not the very best, medical dictionary in the English language, Dunglison's work has been well known for about forty years, and needs no words of praise on our part to recommend it to the members of the medical, and, likewise, of the pharmaceutical profession. The latter especially are in need of such a work, which gives ready and reliable information on thousands of subjects and terms which they are liable to encounter in pursuing their daily avocations, but with which they cannot be expected to be familiar. The work before us fully supplies this want.—*Am. Journ. of Pharm.*, Feb. 1874.

A valuable dictionary of the terms employed in medicine and the allied sciences, and of the relations of the subjects treated under each head. It reflects great credit on its able American author, and well deserves the authority and popularity it has obtained.—*British Med. Journ.*, Oct. 31, 1874.

Few works of this class exhibit a grander monument of patient research and of scientific lore. The extent of the sale of this lexicon is sufficient to testify to its usefulness, and to the great service conferred by Dr. Robley Dunglison on the profession, and indeed on others, by its issue.—*London Lancet*, May 16 1874.

HOBLYN (*RICHARD D.*), *M.D.*

A DICTIONARY OF THE TERMS USED IN MEDICINE AND THE COLLATERAL SCIENCES. Revised, with numerous additions, by ISAAC HAYS, M.D., Editor of the "American Journal of the Medical Sciences." In one large royal 12mo. volume of over 500 double-columned pages; cloth, $1 50; leather, $2 00

It is the best book of definitions we have, and ought always to be upon the student's table.—*Southern Med. and Surg. Journal.*

RODWELL (*G. F.*), *F.R.A.S., &c.*

A DICTIONARY OF SCIENCE: Comprising Astronomy, Chemistry, Dynamics, Electricity, Heat, Hydrodynamics, Hydrostatics, Light, Magnetism, Mechanics, Meteorology, Pneumatics, Sound, and Statics. Preceded by an Essay on the History of the Physical Sciences. In one handsome octavo volume of 694 pages, with many illustrations. cloth, $5.

A CENTURY OF AMERICAN MEDICINE, 1776–1876. By Doctors E. H. Clarke, H. J. Bigelow, S. D. Gross, T. G. Thomas, and J. S. Billings. In one very handsome 12mo. volume of about 350 pages: cloth, $2 25. (*Lately Issued.*)

This work appeared in the pages of the American Journal of the Medical Sciences during the year 1876. As a detailed account of the development of medical science in America, by gentlemen of the highest authority in their respective departments, the profession will no doubt welcome it in a form adapted for preservation and reference.

NEILL (JOHN), M.D., and SMITH (FRANCIS G.), M.D.,
Prof. of the Institutes of Medicine in the Univ. of Penna.

AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE; for the Use and Examination of Students. A new edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of about one thousand pages, with 374 wood-cuts, cloth, $4; strongly bound in leather, with raised bands, $4 75.

HARTSHORNE (HENRY), M.D.,
Professor of Hygiene in the University of Pennsylvania.

A CONSPECTUS OF THE MEDICAL SCIENCES; containing Handbooks on Anatomy, Physiology, Chemistry, Materia Medica, Practical Medicine, Surgery, and Obstetrics. Second Edition, thoroughly revised and improved. In one large royal 12mo. volume of more than 1000 closely printed pages, with 477 illustrations on wood. Cloth, $4 25; leather, $5 00. (*Lately Issued.*)

We can say with the strictest truth that it is the best work of the kind with which we are acquainted. It embodies in a condensed form all recent contributions to practical medicine, and is therefore useful to every busy practitioner throughout our country, besides being admirably adapted to the use of students of medicine. The book is faithfully and ably executed.—*Charleston Med. Journ.*, April, 1875.

The work is intended as an aid to the medical student, and as such appears to admirably fulfil its object by its excellent arrangement, the full compilation of facts, the perspicuity and terseness of language, and the clear and instructive illustrations in some parts of the work.—*American Journ. of Pharmacy*, Philadelphia, July, 1874.

The volume will be found useful, not only to students, but to many others who may desire to refresh their memories with the smallest possible expenditure of time.—*N. Y. Med. Journal*, Sept. 1874.

The student will find this the most convenient and useful book of the kind on which he can lay his hand.—*Pacific Med. and Surg. Journ.*, Aug. 1874.

This is the best book of its kind that we have ever examined. It is an honest, accurate, and concise compend of medical sciences, as fairly as possible representing their present condition. The changes and the additions have been so judicious and thorough as to render it, so far as it goes, entirely trustworthy. If students must have a conspectus, they will be wise to procure that of Dr. Hartshorne.—*Detroit Rev. of Med. and Pharm.*, Aug. 1874.

The work before us has many redeeming features not possessed by others, and is the best we have seen. Dr. Hartshorne exhibits much skill in condensation. It is well adapted to the physician in active practice, who can give but limited time to the familiarizing of himself with the important changes which have been made since he attended lectures. The manual of physiology has also been improved and gives the most comprehensive view of the latest advances in the science possible in the space devoted to the subject. The mechanical execution of the book leaves nothing to be wished for.—*Peninsular Journal of Medicine*, Sept. 1874.

After carefully looking through this conspectus, we are constrained to say that it is the most complete work, especially in its illustrations, of its kind that we have seen.—*Cincinnati Lancet*, Sept. 1874.

The favor with which the first edition of this Compendium was received, was an evidence of its various excellences. The present edition bears evidence of a careful and thorough revision. Dr. Hartshorne possesses a happy faculty of seizing upon the salient points of each subject, and of presenting them in a concise and yet perspicuous manner.—*Leavenworth Med. Herald*, Oct. 1874

LUDLOW (J. L.), M.D.

A MANUAL OF EXAMINATIONS upon Anatomy, Physiology, Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy, and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised and greatly extended and enlarged. With 370 illustrations. In one handsome royal 12mo. volume of 816 large pages. Cloth, $3 25; leather, $3 75.

The arrangement of this volume in the form of question and answer renders it especially suitable for the office examination of students, and for those preparing for graduation.

TANNER (THOMAS HAWKES), M.D., &c.

A MANUAL OF CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS. Third American from the Second London Edition. Revised and Enlarged by TILBURY FOX, M. D., Physician to the Skin Department in University College Hospital, &c. In one neat volume small 12mo., of about 375 pages, cloth, $1 50.

*** On page 3, it will be seen that this work is offered as a premium for procuring new subscribers to the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES."

GRAY (HENRY), F.R.S.,

Lecturer on Anatomy at St. George's Hospital, London.

ANATOMY, DESCRIPTIVE AND SURGICAL. The Drawings by H. V. CARTER, M.D., and Dr. WESTMACOTT. The Dissections jointly by the AUTHOR and Dr. CARTER. With an Introduction on General Anatomy and Development by T. HOLMES, M.A., Surgeon to St. George's Hospital. A new American, from the Eighth enlarged and improved London edition. To which is added "LANDMARKS, MEDICAL AND SURGICAL," by LUTHER HOLDEN, F.R.C.S., author of "Human Osteology," "A Manual of Dissections," etc. In one magnificent imperial octavo volume of 983 pages, with 522 large and elaborate engravings on wood. Cloth, $6; leather, raised bands, $7; half Russia, $7 50. (*Now Ready.*)

The author has endeavored in this work to cover a more extended range of subjects than is customary in the ordinary text-books, by giving not only the details necessary for the student, but also the application of those details in the practice of medicine and surgery, thus rendering it both a guide for the learner, and an admirable work of reference for the active practitioner. The engravings form a special feature in the work, many of them being the size of nature, nearly all original, and having the names of the various parts printed on the body of the cut, in place of figures of reference, with descriptions at the foot. They thus form a complete and splendid series, which will greatly assist the student in obtaining a clear idea of Anatomy, and will also serve to refresh the memory of those who may find in the exigencies of practice the necessity of recalling the details of the dissecting room; while combining, as it does, a complete Atlas of Anatomy, with a thorough treatise on systematic, descriptive, and applied Anatomy, the work will be found of essential use to all physicians who receive students in their offices, relieving both preceptor and pupil of much labor in laying the groundwork of a thorough medical education.

Since the appearance of the last American Edition, the work has received three revisions at the hands of its accomplished editor, Mr. Holmes, who has sedulously introduced whatever has seemed requisite to maintain its reputation as a complete and authoritative standard text-book and work of reference. Still further to increase its usefulness, there has been appended to it the recent work by the distinguished anatomist, Mr. Luther Holden—"Landmarks, Medical and Surgical"—which gives in a clear, condensed and systematic way, all the information by which the practitioner can determine from the external surface of the body the position of internal parts. Thus complete, the work, it is believed, will furnish all the assistance that can be rendered by type and illustration in anatomical study. No pains have been spared in the typographical execution of the volume, which will be found in all respects superior to former issues. Notwithstanding the increase of size, amounting to over 100 pages and 57 illustrations, it will be kept, as heretofore, at a price rendering it one of the cheapest works ever offered to the American profession.

The recent work of Mr Holden, which was noticed by us on p. 53 of this volume, has been added as an appendix, so that, altogether, this is the most practical and complete anatomical treatise available to American students and physicians. The former finds in it the necessary guide in making dissections; a very comprehensive chapter on minute anatomy; and about all that can be taught him on general and special anatomy; while the latter, in its treatment of each region from a surgical point of view, and in the valuable addition of Mr. Holden, will find all that will be essential to him in his practice.—*New Remedies*, Aug 1878.

This work is as near perfection as one could possibly or reasonably expect any book intended as a text-book or a general reference book on anatomy to be. The American publisher deserves the thanks of the profession for appending the recent work of Mr. Holden, "*Landmarks, Medical and Surgical*," which has already been commended as a separate book. The latter work—treating of topographical anatomy—has become an essential to the library of every intelligent practitioner. We know of no book that can take its place, written as it is by a most distinguished anatomist. It would be simply a waste of words to say anything further in praise of Gray's Anatomy, the text-book in almost every medical college in this country, and the daily reference book of every practitioner who has occasion to consult his books on anatomy. The work is simply indispensable, especially this present American edition.—*Va. Med. Monthly*, Sept. 1878.

The addition of the recent work of Mr. Holden, as an appendix, renders this the most practical and complete treatise available to American students, who find in it a comprehensive chapter on minute anatomy, about all that can be taught on general and special anatomy, while its treatment of each region, from a surgical point of view, in the valuable section by Mr Holden, is all that will be essential to them in practice.—*Ohio Medical Recorder*, Aug 1878.

It is difficult to speak in moderate terms of this new edition of "Gray." It seems to be as nearly perfect as it is possible to make a book devoted to any branch of medical science. The labors of the eminent men who have successively revised the eight editions through which it has passed, would seem to leave nothing for future editors to do. The addition of Holden's "Landmarks" will make it as indispensable to the practitioner of medicine and surgery as it has been heretofore to the student. As regards completeness, ease of reference, utility, beauty, and cheapness, it has no rival. No student should enter a medical school without it; no physician can afford to have it absent from his library.—*St. Louis Clin. Record*, Sept. 1878.

ALSO FOR SALE SEPARATE—

HOLDEN (LUTHER), F.R.C.S.,

Surgeon to St. Bartholomew's and the Foundling Hospitals.

LANDMARKS, MEDICAL AND SURGICAL. From the 2d London Ed. In one handsome volume, royal 12mo., of 128 pages. Cloth, 88 cents. (*Now Ready.*)

HEATH (CHRISTOPHER), F.R.C.S.,

Teacher of Operative Surgery in University College, London.

PRACTICAL ANATOMY: A Manual of Dissections. From the Second revised and improved London edition. Edited, with additions, by W. W. KEEN, M. D., Lecturer on Pathological Anatomy in the Jefferson Medical College, Philadelphia. In one handsome royal 12mo. volume of 578 pages, with 247 illustrations. Cloth, $3 50; leather, $4 00.

ALLEN (HARRISON), M.D.

Professor of Physiology in the Univ. of Pa.

A SYSTEM OF HUMAN ANATOMY: INCLUDING ITS MEDICAL and Surgical Relations. For the Use of Practitioners and Students of Medicine With an Introductory Chapter on Histology. By E. O. SHAKESPEARE, M D, Ophthalmologist to the Phila. Hosp. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text. *(Shortly.)*

In this elaborate work, which has been in active preparation for several years, the author has sought to give, not only the details of descriptive anatomy in a clear and condensed form, but also the practical applications of the science to medicine and surgery. The work thus has claims upon the attention of the general practitioner, as well as of the student, enabling him not only to refresh his recollections of the dissecting room, but also to recognize the significance of all variations from normal conditions. The marked utility of the object thus sought by the author is self-evident, and his long experience and assiduous devotion to its thorough development are a sufficient guarantee of the manner in which his aims have been carried out. No pains have been spared with the illustrations. Those of normal anatomy are from original dissections, drawn on stone by Mr. Hermann Faber, with the name of every part clearly engraved upon the figure, after the manner of "Holden" and "Gray," and in every typographical detail it will be the effort of the publisher to render the volume worthy of the very distinguished position which is anticipated for it.

ELLIS (GEORGE VINER)

Emeritus Professor of Anatomy in University College, London.

DEMONSTRATIONS OF ANATOMY; Being a Guide to the Knowledge of the Human Body by Dissection. By GEORGE VINER ELLIS, Emeritus Professor of Anatomy in University College, London. From the Eighth and Revised London Edition. In one very handsome octavo volume of over 700 pages, with 256 illustrations. Cloth, $4.25; leather, $5.25. *(Now Ready)*

This work has long been known in England as the leading authority on practical anatomy, and the favorite guide in the dissecting-room, as is attested by the numerous editions through which it has passed. In the last revision, which has just appeared in London, the accomplished author has sought to bring it on a level with the most recent advances of science by making the necessary changes in his account of the microscopic structure of the different organs, as developed by the latest researches in textural anatomy.

Ellis's Demonstrations is the favorite text-book of the English student of anatomy. In passing through eight editions it has been so revised and adapted to the needs of the student that it would seem that it had almost reached perfection in this special line. The descriptions are clear, and the methods of pursuing anatomical investigations are given with such detail that the book is honestly entitled to its name.—*St. Louis Clinical Record*, June, 1879.

The success of this old manual seems to be as well deserved in the present as in the past volumes. The book seems destined to maintain yet for years its leadership over the English manuals upon dissecting.—*Phila. Med. Times*, May 24, 1879.

As a dissector, or a work to have in hand and studied while one is engaged in dissecting, we regard it as the very best work extant, which is certainly saying a very great deal. As a text-book to be studied in the dissecting-room, it is superior to any of the works upon anatomy.—*Cincinnati Med. News*, May 24, 1879.

We most unreservedly recommend it to every practitioner of medicine who can possibly get it.—*Va. Med. Monthly*, June, 1879.

WILSON (ERASMUS), F.R.S.

A SYSTEM OF HUMAN ANATOMY, General and Special. Edited by W. H. GOBRECHT, M.D, Professor of General and Surgical Anatomy in the Medical College of Ohio. Illustrated with three hundred and ninety-seven engravings on wood. In one large and handsome octavo volume, of over 800 pages; cloth, $4; leather, $5.

SMITH (HENRY H.), M.D., and HORNER (WILLIAM E.), M.D.,

Prof. of Surgery in the Univ. of Penna., &c. *Late Prof. of Anatomy in the Univ. of Penna.*

AN ANATOMICAL ATLAS; Illustrative of the Structure of the Human Body. In one volume, large imperial octavo, cloth, with about six hundred and fifty beautiful figures. $4 50.

SCHÄFER (EDWARD ALBERT), M.D.,

Assistant Professor of Physiology in University College, London.

A COURSE OF PRACTICAL HISTOLOGY: Being an Introduction to the Use of the Microscope. In one handsome royal 12mo. volume of 304 pages, with numerous illustrations: cloth, $2 00. *(Just Issued.)*

HORNER'S SPECIAL ANATOMY AND HISTOLOGY. Eighth edition, extensively revised and modified. In 2 vols. 8vo., of over 1000 pages, with 330 wood cuts: cloth, $6 00

SHARPEY AND QUAIN'S HUMAN ANATOMY. Revised, by JOSEPH LEIDY, M.D., Prof of Anat. in Univ. of Penn. In two octavo vols. of about 1300 pages, with 511 illustrations Cloth, $6 00

BELLAMY'S STUDENT'S GUIDE TO SURGICAL ANATOMY: A Text-book for Students preparing for their Pass Examination. With engravings on wood In one handsome royal 12mo. volume. Cloth. $2 25.

CLELAND'S DIRECTORY FOR THE DISSECTION OF THE HUMAN BODY. In one small volume, royal 12mo. of 182 pages: cloth $1 25.

HARTSHORNE'S HANDBOOK OF ANATOMY AND PHYSIOLOGY. Second edition, revised. In one royal 12mo. vol., with 220 wood cuts; cloth, $1 75.

DALTON (*J. C.*), *M.D.*,

Professor of Physiology in the College of Physicians and Surgeons, New York, &c.

A TREATISE ON HUMAN PHYSIOLOGY. Designed for the use of Students and Practitioners of Medicine. Sixth edition, thoroughly revised and enlarged, with three hundred and sixteen illustrations on wood. In one very beautiful octavo volume, of over 800 pages. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Lately Issued.*)

During the past few years several new works on physiology, and new editions of old works, have appeared, competing for the favor of the medical student, but none will rival this new edition of Dalton. As now enlarged, it will be found also to be, in general, a satisfactory work of reference for the practitioner.—*Chicago Med. Journ. and Examiner*, Jan. 1876.

Prof. Dalton has discussed conflicting theories and conclusions regarding physiological questions with a fairness, a fulness, and a conciseness which lend freshness and vigor to the entire book. But his discussions have been so guarded by a refusal of admission to those speculative and theoretical explanations, which at best exist in the minds of observers themselves as only probabilities, that none of his readers need be led into grave errors while making them a study.—*The Medical Record*, Feb. 19, 1876.

The revision of this great work has brought it forward with the physiological advances of the day, and renders it, as it has ever been, the finest work for students extant.—*Nashville Journ. of Med. and Surg.*, Jan. 1876.

For clearness and perspicuity, Dalton's Physiology commended itself to the student years ago, and was a pleasant relief from the verbose productions which it supplanted. Physiology has, however, made many advances since then—and while the style has been preserved intact, the work in the present edition has been brought up fully abreast of the times. The new chemical notation and nomenclature have also been introduced into the present edition. Notwithstanding the multiplicity of text-books on physiology, this will lose none of its old time popularity. The mechanical execution of the work is all that could be desired.—*Peninsular Journal of Medicine*, Dec. 1875.

This popular text-book on physiology comes to us in its sixth edition with the addition of about fifty per cent. of new matter, chiefly in the departments of pathological chemistry and the nervous system, where the principal advances have been realized. With so thorough revision and additions, that keep the work well up to the times, its continued popularity may be confidently predicted, notwithstanding the competition it may encounter. The publisher's work is admirably done.—*St. Louis Med. and Surg. Journ.*, Dec. 1875.

We heartily welcome this, the sixth edition of this admirable text-book, than which there are none of equal brevity more valuable. It is cordially recommended by the Professor of Physiology in the University of Louisiana, as by all competent teachers in the United States, and wherever the English language is read, this book has been appreciated. The present edition, with its 316 admirably executed illustrations, has been carefully revised and very much enlarged, although its bulk does not seem perceptibly increased.—*New Orleans Medical and Surgical Journal*, March, 1876.

CARPENTER (*WILLIAM B.*), *M.D., F.R.S., F.G.S., F.L.S.*,

Registrar to University of London, &c

PRINCIPLES OF HUMAN PHYSIOLOGY; Edited by HENRY POWER, M.B. Lond., F.R.C.S., Examiner in Natural Sciences, University of Oxford. A new American from the Eighth Revised and Enlarged English Edition, with Notes and Additions, by FRANCIS G. SMITH, M.D., Professor of the Institutes of Medicine in the University of Pennsylvania, etc. In one very large and handsome octavo volume, of 1083 pages, with two plates and 373 engravings on wood. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Issued.*)

We have been agreeably surprised to find the volume so complete in regard to the structure and functions of the nervous system in all its relations, a subject that, in many respects, is one of the most difficult of all, in the whole range of physiology, upon which to produce a full and satisfactory treatise of the class to which the one before us belongs. The additions by the American editor give to the work as it is a considerable value beyond that of the last English edition. In conclusion, we can give our cordial recommendation to the work as it now appears. The editors have, with their additions to the only work on physiology in our language that, in the fullest sense of the word, is the production of a philosopher as well as a physiologist, brought it up as fully as could be expected, if not desired, to the standard of our knowledge of its subject at the present day. It will deservedly maintain the place it has always had in the favor of the medical profession.—*Journ. of Nervous and Mental Disease*, April, 1877.

Such enormous advances have recently been made in our physiological knowledge, that what was perfectly new a year or two ago, looks now as if it had been a received and established fact for years. In this encyclopædic way it is unrivalled. Here, as it seems to us, is the great value of the book: one is safe in sending a student to it for information on almost any given subject, perfectly certain of the fulness of information it will convey, and well satisfied of the accuracy with which it will there be found stated.—*London Med. Times and Gazette*, Feb. 17, 1877.

The merits of "Carpenter's Physiology" are so widely known and appreciated that we need only allude briefly to the fact that in the latest edition will be found a comprehensive embodiment of the results of recent physiological investigation. Care has been taken to preserve the practical character of the original work In fact the entire work has been brought up to date, and bears evidence of the amount of labor that has been bestowed upon it by its distinguished editor, Mr. Henry Power. The American editor has made the latest additions, in order fully to cover the time that has elapsed since the last English edition.—*N. Y. Med Journal*, Jan. 1877.

FOSTER (*MICHAEL*), *M.D., F.R.S.*,

Prof. of Physiology in Cambridge Univ., England.

TEXT-BOOK OF PHYSIOLOGY. Latest edition. In one handsome 12mo. vol. of over 800 pages, with 72 illustrations. Cloth, $3 00. (*Just Ready.*)

Dr. Foster has combined in this work the conflicting desiderata in all text-books—comprehensiveness, brevity, and clearness. After a careful perusal of the whole work we can confidently recommend it, both to the student and the practitioner, as being one of the best text-books on physiology extant.—*The London Lancet.*

LEHMANN'S MANUAL OF CHEMICAL PHYSIOLOGY. Translated from the German, with Notes and Additions, by J. CAMERON MORRIS, M.D. With illustrations on wood. In one octavo volume of 336 pages. Cloth, $2 25.

LEHMANN'S PHYSIOLOGICAL CHEMISTRY. Complete in two large octavo volumes of 1200 pages, with 200 illustrations; cloth, $6.

ATTFIELD (JOHN), Ph.D.,

Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, &c.

CHEMISTRY, GENERAL, MEDICAL, AND PHARMACEUTICAL;

Including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. Eighth edition revised by the author. In one handsome royal 12mo. volume of 700 pages, with illustrations. Cloth, $2 50; leather, $3 00. (*Now Ready.*)

We have repeatedly expressed our favorable opinion of this work, and on the appearance of a new edition of it, little remains for us to say, except that we expect this eighth edition to be as indispensable to us as the seventh and previous editions have been. While the general plan and arrangement have been adhered to, new matter has been added covering the observations made since the former edition The present differs from the preceding one chiefly in these alterations and in about ten pages of useful tables added in the appendix.—*Am. Jour. of Pharmacy*, May, 1879.

A standard work like Attfield's Chemistry need only be mentioned by its name, without further comments. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. The author has bestowed arduous labor on the revision, and the extent of the information thus introduced may be estimated from the fact that the index contains three hundred new references relating to additional material.—*Druggists' Circular and Chemical Gazette*, May, 1879.

This very popular and meritorious work has now reached its eighth edition, which fact speaks in the highest terms in commendation of its excellence. It has now become the principal text-book of chemistry in all the medical colleges in the United States. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. It is scarcely necessary for us to say that it exhibits chemistry in its present advanced state.—*Cincinnati Medical News*, April, 1879.

The popularity which this work has enjoyed is owing to the original and clear disposition of the facts of the science, the accuracy of the details, and the omission of much which freights many treatises heavily without bringing corresponding instruction to the reader. Dr. Attfield writes for students, and primarily for medical students; he always has an eye to the pharmacopœia and its officinal preparations; and he is continually putting the matter in the text so that it responds to the questions with which each section is provided. Thus the student learns easily, and can always refresh and test his knowledge.—*Med and Surg. Reporter*, April 19, '79.

We noticed only about two years and a half ago the publication of the preceding edition, and remarked upon the exceptionally valuable character of the work. The work now includes the whole of the chemistry of the pharmacopœia of the United States, Great Britain, and India.—*New Remedies*, May, 1879.

GREENE (WILLIAM H.), M.D.,

Demonstrator of Chemistry in Med. Dept., Univ. of Penna.

A MANUAL OF MEDICAL CHEMISTRY. For the Use of Students.

Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 312 pages. With illustrations. Cloth, $1 75. (*Now Ready.*)

It is well written, and gives the latest views on vital chemistry, a subject with which most physicians are not sufficiently familiar. To those who may wish to improve their knowledge in that direction, we can heartily recommend this work as being worthy of a careful perusal.—*Phila. Med. and Surg. Reporter*, April 24, 1880.

The little work before us is one which we think will be studied with pleasure and profit. The descriptions, though brief, are clear, and in most cases sufficient for the purpose This book will, in nearly all cases, meet general approval.—*Am. Journ. of Pharmacy*, April, 1880.

CLASSEN (ALEXANDER),

Professor in the Royal Polytechnic School, Aix-la-Chapelle.

ELEMENTARY QUANTITATIVE ANALYSIS. Translated with

notes and additions by EDGAR F. SMITH, Ph.D., Assistant Prof. of Chemistry in the Towne Scientific School, Univ. of Penna. In one handsome royal 12mo. volume, of 324 pages, with illustrations; cloth, $2 00. (*Just Ready.*)

It is probably the best manual of an elementary nature extant, inasmuch as its methods are the best. It teaches by examples, commencing with single determinations, followed by separations, and then advancing to the analysis of minerals and such products as are met with in applied chemistry. It is an indispensable book for students in chemistry.—*Boston Journ. of Chemistry*, Oct. 1878.

GALLOWAY (ROBERT), F.C.S.,

Prof of Applied Chemistry in the Royal College of Science for Ireland, etc.

A MANUAL OF QUALITATIVE ANALYSIS. From the Fifth Lon-

don Edition. In one neat royal 12mo. volume, with illustrations; cloth, $2 75. (*Lately Issued.*)

REMSEN (IRA), M.D., Ph.D.,

Professor of Chemistry in the Johns Hopkins University, Baltimore.

PRINCIPLES OF THEORETICAL CHEMISTRY, with special reference

to the Constitution of Chemical Compounds. In one handsome royal 12mo. vol. of over 232 pages: cloth, $1 50. (*Just Issued.*)

BOWMAN'S INTRODUCTION TO PRACTICAL CHEMISTRY, INCLUDING ANALYSIS. Sixth American, from the sixth and revised London edition With numerous illustrations. In one neat vol., royal 12mo., cloth, $2 25.

WÖHLER AND FITTIG'S OUTLINES OF ORGANIC CHEMISTRY Translated with additions from the Eighth German Edition. By IRA REMSEN, M.D., Ph.D., Prof. of Chemistry and Physics in Williams College, Mass. In one volume, royal 12mo. of 550 pp., cloth, $3.

FOWNES (GEORGE), Ph.D.

A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and Practical.

Revised and corrected by HENRY WATTS, B.A., F.R.S., author of "A Dictionary of Chemistry," etc. With a colored plate, and one hundred and seventy-seven illustrations. A new American, from the twelfth and enlarged London edition. Edited by ROBERT BRIDGES, M.D. In one large royal 12mo. volume, of over 1000 pages; cloth, $2 75; leather, $3 25. (*Just Issued.*)

This work, inorganic and organic, is complete in one convenient volume. In its earliest editions it was fully up to the latest advancements and theories of that time. In its present form, it presents, in a remarkably convenient and satisfactory manner, the principles and leading facts of the chemistry of *to-day*. Concerning the manner in which the various subjects are treated, much deserves to be said, and mostly, too, in praise of the book. A review of such a work as *Fownes's Chemistry* within the limits of a book-notice for a medical weekly is simply out of the question.—*Cincinnati Lancet and Clinic*, Dec. 14, 1878.

When we state that, in our opinion, the present edition sustains in every respect the high reputation which its predecessors have acquired and enjoyed, we express therewith our full belief in its intrinsic value as a text-book and work of reference.—*Am. Journ. of Pharm.*, Aug. 1878.

The conscientious care which has been bestowed upon it by the American and English editors renders it still, perhaps, the best book for the student and the practitioner who would keep alive the acquisitions of his student days. It has, indeed, reached a somewhat formidable magnitude with its more than a thousand pages, but with less than this no fair representation of chemistry as it now is can be given. The type is small but very clear, and the sections are very lucidly arranged to facilitate study and reference.—*Med and Surg. Reporter*, Aug 3, 1878

The work is too well known to American students to need any extended notice; suffice it to say that the revision by the English editor has been faithfully done, and that Professor Bridges has added some fresh and valuable matter, especially in the inorganic chemistry. The book has always been a favorite in this country, and in its new shape bids fair to retain all its former *prestige*.—*Boston Jour. of Chemistry*, Aug. 1878.

It will be entirely unnecessary for us to make any remarks relating to the general character of Fownes' Manual. For over twenty years it has held *the* foremost place as a text-book, and he elaborate and thorough revisions which have been made from time to time leave little chance for any wide awake rival to step before it.—*Canadian Pharm. Jour.*, Aug. 1878.

As a manual of chemistry it is without a superior in the language.—*Md. Med. Jour.*, Aug. 1878.

BLOXAM (C. L.),

Professor of Chemistry in King's College, London.

CHEMISTRY, INORGANIC AND ORGANIC.

From the Second London Edition. In one very handsome octavo volume, of 700 pages, with about 300 illustrations. Cloth, $4 00; leather, $5 00. (*Lately Issued.*)

We have in this work a complete and most excellent text-book for the use of schools, and can heartily recommend it as such.—*Boston Med. and Surg. Journ.*, May 28, 1874.

The above is the title of a work which we can most conscientiously recommend to students of chemistry. It is as easy as a work on chemistry could be made, at the same time that it presents a full account of that science as it now stands. We have spoken of the work as admirably adapted to the wants of students; it is quite as well suited to the requirements of practitioners who wish to review their chemistry, or have occasion to refresh their memories on any point relating to it. In a word, it is a book to be read by all who wish to know what is the chemistry of the present day.—*American Practitioner*, Nov. 1873.

It would be difficult for a practical chemist and teacher to find any material fault with this most admirable treatise. The author has given us almost a cyclopædia within the limits of a convenient volume, and has done so without penning the *useless* paragraphs too commonly making up a great part of the bulk of many cumbrous works. The progressive scientist is not disappointed when he looks for the record of new and valuable processes and discoveries, while the cautious conservative does not find its pages monopolized by uncertain theories and speculations. A peculiar point of excellence is the crystallized form of expression in which great truths are expressed in very short paragraphs. One is surprised at the brief space allotted to an important topic, and yet, after reading it, he feels that little, if any more should have been said. Altogether, it is seldom you see a text-book so nearly faultless.—*Cincinnati Lancet*, Nov. 1873.

CLOWES (FRANK), D.Sc., London.

Senior Science-Master at the High School, Newcastle-under-Lyme, etc.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS.

Specially adapted for Use in the Laboratories of Schools and Colleges and by Beginners. Second American from the Third and Revised English Edition. In one very handsome royal 12mo. volume of 372 pages, with 47 illustrations. Cloth, $2 50. (*Just Ready.*)

It is short, concise, and eminently practical. We therefore heartily commend it to students, and especially to those who are obliged to dispense with a master. Of course a teacher is in every way desirable, but a good degree of technical skill and practical knowledge can be attained with no other instructor than the very valuable handbook now under consideration.—*St Louis Clin. Record*, Oct. 1877.

The work is so written and arranged that it can be comprehended by the student without a teacher, and the descriptions and directions for the various work are so simple, and yet concise, as to be interesting and intelligible. The work is unincumbered with theoretical deductions, dealing wholly with the practical matter, which it is the aim of this comprehensive text-book to impart. The accuracy of the analytical methods are vouched for from the fact that they have all been worked through by the author and the members of his class, from the printed text. We can heartily recommend the work to the student of chemistry as being a reliable and comprehensive one.—*Druggists' Advertiser*, Oct. 15, 1877.

KNAPP'S TECHNOLOGY; or Chemistry Applied to the Arts and to Manufactures. With American additions by Prof. WALTER R. JOHNSON. In two very handsome octavo volumes, with 500 wood engravings, cloth, $6 00.

PARRISH (*EDWARD*),

Late Professor of Materia Medica in the Philadelphia College of Pharmacy.

A TREATISE ON PHARMACY. Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmaceutist. With many Formulæ and Prescriptions. Fourth Edition, thoroughly revised, by THOMAS S. WIEGAND. In one handsome octavo volume of 977 pages, with 280 illustrations; cloth, $5 50; leather, $6 50; half Russia, $7. (*Lately Issued.*)

Of Dr. Parrish's great work on pharmacy it only remains to be said that the editor has accomplished his work so well as to maintain, in this fourth edition, the high standard of excellence which it had attained in previous editions, under the editorship of its accomplished author. This has not been accomplished without much labor, and many additions and improvements, involving changes in the arrangement of the several parts of the work, and the addition of much new matter. With the modifications thus effected it constitutes, as now presented, a compendium of the science and art indispensable to the pharmacist, and of the utmost value to every practitioner of medicine desirous of familiarizing himself with the pharmaceutical preparation of the articles which he prescribes for his patients.—*Chicago Med. Journ.*, July, 1874.

The work is eminently practical, and has the rare merit of being readable and interesting, while it preserves a strictly scientific character. The whole work reflects the greatest credit on author, editor and publisher. It will convey some idea of the liberality which has been bestowed upon its production when we mention that there are no less than 280 carefully executed illustrations. In conclusion, we heartily recommend the work, not only to pharmacists, but also to the multitude of medical practitioners who are obliged to compound their own medicines. It will ever hold an honored place on our own bookshelves.—*Dublin Med. Press and Circular*, Aug. 12, 1874.

We expressed our opinion of a former edition in terms of unqualified praise, and we are in no mood to detract from that opinion in reference to the present edition, the preparation of which has fallen into competent hands. It is a book with which no pharmacist can dispense, and from which no physician can fail to derive much information of value to him in practice.—*Pacific Med. and Surg. Journ.*, June, '74.

Perhaps one, if not the most important book upon pharmacy which has appeared in the English language has emanated from the transatlantic press. "Parrish's Pharmacy" is a well-known work on this side of the water and the fact shows us that a really useful work never becomes merely local in its fame. Thanks to the judicious editing of Mr. Wiegand, the posthumous edition of "Parrish" has been saved to the public with all the mature experience of its author, and perhaps none the worse for a dash of new blood.—*Lond. Pharm. Journal*, Oct. 17, 1874.

GRIFFITH (*ROBERT E.*), *M.D.*

A UNIVERSAL FORMULARY, Containing the Methods of Preparing and Administering Officinal and other Medicines. The whole adapted to Physicians and Pharmaceutists. Third edition, thoroughly revised, with numerous additions, by JOHN M. MAISCH, Professor of Materia Medica in the Philadelphia College of Pharmacy. In one large and handsome octavo volume of about 800 pp., cl., $4 50; leather, $5 50. (*Lately Issued.*)

To the druggist a good formulary is simply indispensable, and perhaps no formulary has been more extensively used than the well-known work before us. Many physicians have to officiate, also, as druggists. This is true especially of the country physician, and a work which shall teach him the means by which to administer or combine his remedies in the most efficacious and pleasant manner, will always hold its place upon his shelf. A formulary of this kind is of benefit also to the city physician in largest practice.—*Cincinnati Hosp.* Feb. 21, 1874.

A more complete formulary than it is in its present form the pharmacist or physician could hardly desire. To the first some such work is indispensable, and it is hardly less essential to the practitioner who compounds his own medicines. Much of what is contained in the introduction ought to be committed to memory by every student of medicine. As a help to physicians it will be found invaluable, and doubtless will make its way into libraries not already supplied with a standard work of the kind.—*The American Practitioner*, Louisville, July, '74.

FARQUHARSON (*ROBERT*), *M.D.*,

Lecturer on Materia Medica at St. Mary's Hospital Medical School.

A GUIDE TO THERAPEUTICS AND MATERIA MEDICA. Second American edition, revised by the Author. Enlarged and adapted to the U. S. Pharmacopœia. By FRANK WOODBURY, M.D. In one neat royal 12mo. volume of 498 pages: cloth, $2.25. (*Just Ready.*)

The appearance of a new edition of this convenient and handy book in less than two years may certainly be taken as an indication of its usefulness. Its convenient arrangement, and its terseness, and, at the same time, completeness of the information given, make it a handy book of reference.—*Am. Journ of Pharmacy*, June, 1879.

This work contains in moderate compass such well-digested facts concerning the physiological and therapeutical action of remedies as are reasonably established up to the present time. By a convenient arrangement the corresponding effects of each article in health and disease are presented in parallel columns, not only rendering reference easier, but also impressing the facts more strongly upon the mind of the reader. The book has been adapted to the wants of the American student, and copious notes have been introduced, embodying the latest revision of the Pharmacopœia, together with the antidotes to the more prominent poisons, and such of the newer remedial agents as seemed necessary to the completeness of the work. Tables of weights and measures, and a good alphabetical index end the volume.—*Druggists' Circular and Chemical Gazette*, June, 1879.

It is a pleasure to think that the rapidity with which a second edition is demanded may be taken as an indication that the sense of appreciation of the value of reliable information regarding the use of remedies is not entirely overwhelmed in the cultivation of pathological studies, characteristic of the present day. This work certainly merits the success it has so quickly achieved.—*New Remedies*, July, '79.

CHRISTISON'S DISPENSATORY. With copious additions, and 213 large wood engravings. By R. EGLESFELD GRIFFITH, M.D. One vol. 8vo., pp. 1000, cloth, $4 00.

CARPENTER'S PRIZE ESSAY ON THE USE OF ALCOHOLIC LIQUORS IN HEALTH AND DISEASE. New edition, with a Preface by D. F. CONDIE, M.D., and explanations of scientific words. In one neat 12mo. volume, pp. 178, cloth, 60 cents.

STILLE (ALFRED), M.D., LL.D., *Prof. of Theory and Practice of Medicine and of Clinical Med. in Univ. of Pa.*

MAISCH (JOHN M.), Ph.D., *Prof. of Mat. Med. and Bot. in Phila. Coll. Pharmacy, Secy. to the American Pharmaceutical Association.*

THE NATIONAL DISPENSATORY: Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of 1692 pages, with 239 illustrations. Extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25. (*Now Ready.*)

PREFACE TO THE SECOND EDITION.

The demand which has exhausted in a few months an unusually large edition of the National Dispensatory is doubly gratifying to the authors, as showing that they were correct in thinking that the want of such a work was felt by the medical and pharmaceutical professions, and that their efforts to supply that want have been acceptable. This appreciation of their labors has stimulated them in the revision to render the volume more worthy of the very marked favor with which it has been received. The first edition of a work of such magnitude must necessarily be more or less imperfect; and though but little that is new and important has been brought to light in the short interval since its publication, yet the length of time during which it was passing through the press rendered the earlier portions more in arrears than the later. The opportunity for a revision has enabled the authors to scrutinize the work as a whole, and to introduce alterations and additions wherever there has seemed to be occasion for improvement or greater completeness. The principal changes to be noted are the introduction of several drugs under separate headings, and of a large number of drugs, chemicals, and pharmaceutical preparations classified as allied drugs and preparations under the heading of more important or better known articles: these additions comprise in part nearly the entire German Pharmacopœia and numerous articles from the French Codex. All new investigations which came to the authors' notice up to the time of publication have received due consideration.

The series of illustrations has undergone a corresponding thorough revision. A number have been added, and still more have been substituted for such as were deemed less satisfactory.

The new matter embraced in the text is equal to nearly one hundred pages of the first edition. Considerable as are these changes as a whole, they have been accommodated by an enlargement of the page without increasing unduly the size of the volume.

While numerous additions have been made to the sections which relate to the physiological action of medicines and their use in the treatment of disease, great care has been taken to make them as concise as was possible without rendering them incomplete or obscure. The doses have been expressed in the terms both of troy weight and of the metrical system, for the purpose of making those who employ the Dispensatory familiar with the latter, and paving the way for its introduction into general use.

The Therapeutical Index has been extended by about 2250 new references, making the total number in the present edition about 6000.

The articles there enumerated as remedies for particular diseases are not only those which, in the authors' opinion, are curative, or even beneficial, but those also which have at any time been employed on the ground of popular belief or professional authority. It is often of as much consequence to be acquainted with the worthlessness of certain medicines or with the narrow limits of their power, as to know the well attested virtues of others and the conditions under which they are displayed. An additional value possessed by such an Index is, that it contains the elements of a natural classification of medicines, founded upon an analysis of the results of experience, which is the only safe guide in the treatment of disease.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since the previous publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Jour. of Pharmacy*, Nov. 1879.

It is with great pleasure that we announce to our readers the appearance of a *second* edition of the National Dispensatory. The total exhaustion of the first edition in the short space of six months, is a sufficient testimony to the value placed upon the work by the profession. It appears that the rapid sale of the first edition must have induced both the editors and the publisher to make preparations for a new edition immediately after the first had been issued, for we find a large amount of new matter added and a good deal of the previous text altered and improved, which proves that the authors do not intend to let the grass grow under their feet, but to keep the work up to the time.—*New Remedies*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on this subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only *national*, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Medical Journal*, Nov. 1879.

It is by far more international or universal than any other book of the kind in our language, and more comprehensive in every sense.—*Pacific Med. and Surg. Journ.*, Oct. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practising physician can afford to be without the National Dispensatory.—*Canada Med. and Surg. Journ.*, Feb. 1880.

STILLÉ (ALFRED), M. D.,

Professor of Theory and Practice of Medicine in the University of Penna.

THERAPEUTICS AND MATERIA MEDICA; a Systematic Treatise on the Action and Uses of Medicinal Agents, including their Description and History.

Fourth edition, revised and enlarged. In two large and handsome 8vo. vols. of about 2000 pages. Cloth, $10; leather, $12; half Russia, $13. (*Lately Issued.*)

It is unnecessary to do much more than to announce the appearance of the fourth edition of this well known and excellent work.—*Brit. and For. Med.-Chir. Review*, Oct 1875

For all who desire a complete work on therapeutics and materia medica for reference, in cases involving medico-legal questions, as well as for information concerning remedial agents, Dr. Stillé's is "par excellence" the work. Being out of print, by the exhaustion of former editions, the author has laid the profession under renewed obligations, by the careful revision, important additions, and timely reissuing a work not exactly supplemented by any other in the English language, if in any language. The mechanical execution handsomely sustains the well-known skill and good taste of the publisher.—*St. Louis Med. and Surg. Journal*, Dec 1874.

From the publication of the first edition "Stillé's Therapeutics" has been one of the classics; its absence from our libraries would create a vacuum which could be filled by no other work in the language, and its presence supplies, in the two volumes of the present edition, a whole cyclopædia of therapeutics.—*Chicago Medical Journal*, Feb. 1876.

The rapid exhaustion of three editions and the universal favor with which the work has been received by the medical profession, are sufficient proof of its excellence as a repertory of practical and useful information for the physician. The edition before us fully sustains this verdict, as the work has been carefully revised and in some portions rewritten, bringing it up to the present time by the admission of chloral and croton-chloral nitrite of amyl, bichloride of methylene, methylic ether, lithium compounds, gelseminum, and other remedies.—*Am. Journ. of Pharmacy*, Feb. 1876.

We can hardly admit that it has a rival in the multitude of its citations and the fulness of its research into clinical histories, and we must assign it a place in the physician's library; not, indeed, as fully representing the present state of knowledge in pharmacodynamics, but as by far the most complete treatise upon the clinical and practical side of the question.—*Boston Med. and Surg. Journal*, Nov. 5, 1874.

CORNIL (V.), AND RANVIER (L.),

Prof. in the Faculty of Med., Paris. *Prof in the College of France.*

MANUAL OF PATHOLOGICAL HISTOLOGY.

Translated, with Notes and Additions, by E. O. SHAKESPEARE, M. D., Pathologist and Ophthalmic Surgeon to Philada. Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in Univ. of Penna., and by HENRY C. SIMES, M D., Demonstrator of Pathological Histology in the Univ. of Pa. In one very handsome octavo volume of over 700 pages, with over 350 illustrations. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Ready.*)

The work of Cornil and Ranvier is so well known as a lucid and accurate text-book on its important subject, that no apology is needed in presenting a translation of it to the American profession. It is only necessary to say that the labors of Drs. Shakespeare and Simes have been by no means confined to the task of rendering the work into English. As it appeared in France, in successive portions, between 1868 and 1876, a part of it, at least, was somewhat in arrears of the present state of science, while the diffuseness of other portions rendered condensation desirable. The translators have, therefore, sought to bring the work up to the day, and, at the same time, to reduce it in size, as far as practicable, without impairing its completeness These changes will be found throughout the volume, the most extensive being in the sections devoted to Sarcoma, Carcinoma, Tuberculosis, the Bloodvessels, the Mammæ, and the classification of tumors Corresponding modifications have been made in the very extensive and beautiful series of illustrations, and every care has been taken in the typographical execution to render it one of the most attractive volumes which have issued from the American press.

We have no hesitation in cordially recommending the English translation of Cornil & Ranvier's "Pathological Histology" as the best work of the kind in any language, and as giving to its readers a trustworthy guide in obtaining a broad and solid basis for the appreciation of the practical bearings of pathological anatomy.—*Am. Journ. of Med. Sciences*, April, 1868.

This important work, in its American dress, is a welcome offering to all students of the subjects which it treats. The great mass of material is arranged naturally and comprehensively. The classification of tumors is clear and full, so far as the subject admits of definition, and this one chapter is worth the price of the book. The illustrations are copious and well chosen. Without the slightest hesitation, the translators deserve honest thanks for placing this indispensable work in the hands of American students.—*Phila. Med. Times*, April 24, 1880

This volume we cordially commend to the profession. It will prove a valuable, almost necessary, addition to the libraries of students who are to be physicians, and to the libraries of students who are physicians.—*American Practitioner*, June, 1880.

Their book is not a compilation of the work of others, but has been written in the laboratory beside the microscope. It bears the marks of personal knowledge and investigation upon every page, controlled by and contrasting the work of others. . . . In short, its translation has made it the best work in pathology attainable in our language, one that every student certainly ought to have.—*Archives of Medicine*, April, 1880.

This work, in the original, has for years past occupied a prominent place in the library of French pathologists, as we should naturally be led to believe from the reputation of the distinguished authors. Now that it has been presented to the English student for the first time, it will be perused with unusual interest. The illustrations are by no means the least valuable part of the work. Indispensable as they are to any work of this nature, in the work before us the artist has succeeded in producing cuts which will prove unusually valuable to the reader. The translation is well done, and gives evidence throughout the volume that it was made by a person thoroughly conversant with the subject.—*N. Y. Med. Gazette*, Feb. 28, 1880.

GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY. Translated, with Notes and Additions, by JOSEPH LEIDY, M. D. In one volume, very large imperial quarto, with 320 copper-plate figures, plain and colored, cloth. $4 00.

PAVY'S TREATISE ON THE FUNCTION OF DIGESTION: its Disorders and their Treatment. From the second London edition In one handsome volume, small octavo, cloth, $2 00.

FENWICK (SAMUEL), M.D.,

Assistant Physician to the London Hospital.

THE STUDENT'S GUIDE TO MEDICAL DIAGNOSIS.

From the Third Revised and Enlarged English Edition. With eighty-four illustrations on wood. In one very handsome volume, royal 12mo., cloth, $2 25. (*Just Issued.*)

GREEN (T. HENRY), M.D.,

Lecturer on Pathology and Morbid Anatomy at Charing-Cross Hospital Medical School, etc.

PATHOLOGY AND MORBID ANATOMY.

Third American, from the Fourth Enlarged and Revised English Edition. In one very handsome octavo volume of 332 pages, with 132 illustrations; cloth, $2 25. (*Now Ready.*)

This is unquestionably one of the best manuals on the subject of pathology and morbid anatomy that can be placed in the student's hands, and we are glad to see it kept up to the times by new editions. Each edition is carefully revised by the author, with the view of making it include the most recent advances in pathology, and of omitting whatever may have become obsolete.—*N. Y. Med. Jour.*, Feb. 1879.

The treatise of Dr. Green is compact, clearly expressed, up to the times, and popular as a text-book, both in England and America. The cuts are sufficiently numerous, and usually well made. In the present edition, such new matter has been added as was necessary to embrace the later results in pathological research. No doubt it will continue to enjoy the favor it has received at the hands of the profession.—*Med. and Surg. Reporter*, Feb. 1, 1879.

For practical, ordinary daily use, this is undoubtedly the best treatise that is offered to students of pathology and morbid anatomy.—*Cincinnati Lancet and Clinic*, Feb. 8, 1879.

BRISTOWE (JOHN SYER), M.D., F.R.C.P.,

Physician and Joint Lecturer on Medicine, St. Thomas's Hospital.

A TREATISE ON THE PRACTICE OF MEDICINE.

Second American edition, revised by the Author. Edited, with Additions, by JAMES H. HUTCHINSON, M.D., Physician to the Penna. Hospital. In one handsome octavo volume of nearly 1200 pages. With illustrations. Cloth, $5 00; leather, $6 00; half Russia, $6 50. (*Now Ready.*)

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. We see no reason to modify the high opinion previously expressed with regard to Dr. Bristowe's work, except by adding our appreciation of the careful labors of the author in following the lateral growth of medical science. The chapter on diseases of the skin and of the nervous system, with a new one on insanity compiled from the best sources outside of the author's own long experience, and the valuable portion relating to general pathology, aid greatly in completing an exceptionally good book for purposes of reference and instruction — *Boston Medical and Surgical Journal*, February, 1880.

What we said of the first edition, we can, with increased emphasis, repeat concerning this: "Every page is characterized by the utterances of a thoughtful man. What has been said, has been well said, and the book is a fair reflex of all that is *certainly known* on the subjects considered."—*Ohio Med. Recorder*, Jan. 7, 1880.

The views of the author are expressed with precision and sufficient promptness to impress the student with the weight of his authority; and should the medical professor differ on any subject from his doctrine, he will need to find strong arguments to carry his class to the opposite conclusion.—*N. O. Med. and Surg. Journ.*, Feb. 1880.

The reader will find every conceivable subject connected with the practice of medicine ably presented, in a style at once clear, interesting, and concise. The additions made by Dr. Hutchinson are appropriate and practical, and greatly add to its usefulness to American readers.—*Buffalo Med. and Surg. Journ.*, March, 1880.

We regard it as an excellent work for students and for practitioners. It is clearly written, the author's style is attractive, and it is especially to be commended for its excellent exposition of the pathology and clinical phenomena of disease.—*St. Louis Clin. Record*, Feb. 1880.

HABERSHON (S. O.), M.D.

Senior Physician to and late Lecturer on the Principles and Practice of Medicine at Guy's Hospital, etc.

ON THE DISEASES OF THE ABDOMEN, COMPRISING THOSE

of the Stomach, and other parts of the Alimentary Canal, Œsophagus, Cæcum, Intestines, and Peritoneum. Second American, from the third enlarged and revised English edition. With illustrations. In one handsome octavo volume of over 500 pages. Cloth, $3 50. (*Now Ready.*)

This valuable treatise on diseases of the stomach and abdomen has been out of print for several years, and is therefore not so well known to the profession as it deserves to be. It will be found a cyclopædia of information, systematically arranged, on all diseases of the alimentary tract, from the mouth to the rectum. A fair proportion of each chapter is devoted to symptoms, pathology, and therapeutics. The present edition is fuller than former ones in many particulars, and has been thoroughly revised and amended by the author. Several new chapters have been added, bringing the work fully up to the times, and making it a volume of interest to the practitioner in every field of medicine and surgery. Perverted nutrition is in some form associated with all diseases we have to combat, and we need all the light that can be obtained on a subject so broad and general. Dr Habershon's work is one that every practitioner should read and study for himself.—*N. Y. Med. Journ.*, April, 1879.

LA ROCHE ON YELLOW FEVER, considered in its Historical, Pathological, Etiological, and Therapeutical Relations. In two large and handsome octavo volumes of nearly 1500 pp., cloth. $7 00.

STOKES' LECTURES ON FEVER. Edited by JOHN WILLIAM MOORE, M.D., Assistant Physician to the Cork Street Fever Hospital. In one neat 8vo volume, cloth, $1 00.

HOLLAND'S MEDICAL NOTES AND REFLECTIONS. 1 vol. 8vo., pp. 500, cloth. $3 50.

BARLOW'S MANUAL OF THE PRACTICE OF MEDICINE. With Additions by D. F. CONDIE M. D. 1 vol. 8vo., pp. 600, cloth. $2 50.

TODD'S CLINICAL LECTURES ON CERTAIN ACUTE DISEASES. In one neat octavo volume, of 320 pp., cloth. $2 50.

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; designed for the use of Students and Practitioners of Medicine. Fifth edition, entirely rewritten and much improved. In one large and closely printed octavo volume of 1153 pp. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7. (*Just Ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

In preparing the fifth edition of this treatise, the author has been thoroughly mindful of the progress of medicine since the publication of the fourth edition in 1873. Time and labor have not been spared in the endeavor to bring the work in all respects up to the present state of medical knowledge.

Dr. William H. Welch, Lecturer on Pathological Histology in the Bellevue Hospital Medical College, has contributed in Part I. the first seven chapters, embracing the general pathology of the solid tissues and of the blood. He has also revised, and in great part rewritten, the descriptions of the anatomical characters of the diseases considered in the rest of the volume. It is believed that these portions of the work will serve as a digest of the essential facts pertaining to general and special pathological anatomy, as far as this important branch of study bears upon practical medicine.

In the other portions of the treatise many changes will be found, which have somewhat enlarged the size of the volume, in spite of the omission of a considerable amount of matter, and the rewriting of many portions with a special view to condensation. Among these changes may be mentioned numerous improvements in the arrangement, including the classification of the diseases of the nervous system on an anatomical in place of a symptomatic basis, and the consideration of various diseases not embraced in previous editions. In short, the eliminations, substitutions, and additions render the present edition virtually a new work.

In making changes, the author has not been influenced by any sense of obligation to maintain consistency of views with the previous editions of this treatise, or with other works which he has written. If statements be found to vary from those made at a prior date, the simple explanation is that the latter, in the light of more recent reflection and enlarged knowledge, seem to him no longer tenable. He has endeavored to regard his own past writings, in this point of view, divested of the partiality of authorship, and to subject them to as critical an examination as if they were the writings of another.

BY THE SAME AUTHOR.

CLINICAL MEDICINE; a Systematic Treatise on the Diagnosis and Treatment of Diseases. Designed for Students and Practitioners of Medicine. In one large and handsome octavo volume of 795 pages; cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

The eminent teacher who has written the volume under consideration has recognized the needs of the American profession, and the result is all that we could wish. The style in which it is written is peculiarly the author's; it is clear and forcible, and marked by those characteristics which have rendered him one of the best writers and teachers this country has ever produced. We have not space for so full a consideration of this remarkable work as we would desire.—*St. Louis Clin. Record*, Oct. 1879.

It is here that the skill and learning of the great clinician are displayed. He has given us a storehouse of medical knowledge, excellent for the student, convenient for the practitioner, the result of a long life of the most faithful clinical work, collected by an energy as vigilant and systematic as untiring, and weighed by a judgment no less clear than his observation is close.—*Archives of Medicine*, Dec. 1879.

To give an adequate and useful conspectus of the extensive field of modern clinical medicine is a task of no ordinary difficulty; but to accomplish this consistently, with brevity and clearness, the different subjects and their several parts receiving the attention which, relatively to their importance, medical opinion claims for them, is still more difficult. This task we feel bound to say has been executed with more than partial success by Dr Flint, whose name is already familiar to students of advanced medicine in this country as that of the author of two works of great merit on special subjects, and of numerous papers, exhibiting much originality and extensive research.—*The Dublin Journal*, Dec. 1879.

There is every reason to believe that this book will be well received. The active practitioner is frequently in need of some work that will enable him to obtain information in the diagnosis and treatment of cases with comparatively little labor. Dr. Flint has the faculty of expressing himself clearly, and at the same time so concisely as to enable the searcher to traverse the entire ground of his search, and at the same time obtain all that is essential, without plodding through an interminable space.—*N. Y. Med. Jour.*, Nov. 1879.

The great object is to place before the reader the latest observations and experience in diagnosis and treatment. Such a work is especially valuable to students. It is complete in its special design, and yet so condensed, that he can by its aid, keep up with the lectures on practice without neglecting other branches. It will not escape the notice of the practitioner that such a work is most valuable in culling points in diagnosis and treatment in the intervals between the daily rounds of visits since he can in a few minutes refresh his memory, or learn the latest advance in the treatment of diseases which demand his instant attention.—*Cincinnati Lancet and Clinic*, Oct. 25, 1879.

BY THE SAME AUTHOR.

ESSAYS ON CONSERVATIVE MEDICINE AND KINDRED TOPICS. In one very handsome royal 12mo. volume. Cloth, $1 38. (*Just Issued.*)

DAVIS'S CLINICAL LECTURES ON VARIOUS IMPORTANT DISEASES; being a collection of the Clinical Lectures delivered in the Medical Wards of Mercy Hospital, Chicago. Edited by FRANK H DAVIS, M.D. Second edition, enlarged. In one handsome royal 12mo. volume. Cloth, $1 75.

THE CYCLOPÆDIA OF PRACTICAL MEDICINE: comprising Treatises on the Nature and Treatment of Diseases, Materia Medica and Therapeutics, Diseases of Women and Children, Medical Jurisprudence, etc. etc. By DUNGLISON, FORBES, TWEEDIE, and CONOLLY. In four large super-royal octavo volumes, of 3264 double-columned pages, strongly and handsomely bound in leather, $15; cloth, $11.

STURGES'S INTRODUCTION TO THE STUDY OF CLINICAL MEDICINE. Being a Guide to the Investigation of Disease. In one handsome 12mo. volume, cloth, $1 25. (*Lately Issued.*)

RICHARDSON (*BENJ. W.*), *M.D., F.R.S., M.A., LL.D., F.S.A.*,
Fellow of the Royal College of Physicians, London.

PREVENTIVE MEDICINE. In one octavo volume of about 500 pages. (*In Press.*)

The immense strides taken by medical science during the last quarter of a century have had no more conspicuous field of progress than the causation of disease. Not only has this led to marked advance in therapeutics, but it has given rise to a virtually new department of medicine—the prevention of disease—more important, perhaps, in its ultimate results than even the investigation of curative processes. Yet thus far there has been no attempt to gather into a systematic and intelligible shape the accumulation of knowledge thus far acquired on this most interesting subject. Fortunately, the task has been at last undertaken by a writer who of all others is, perhaps, best qualified for its performance, and the result of his labors can hardly fail to mark an epoch in the history of medical science. The plan adopted for the execution of this novel design can best be explained in his own words:—

"With the object here expressed I write this volume. I have nothing to say in it that has any relation to the cure of disease, but I base it nevertheless on the curative side of medical learning. In other words, I trace the diseases from their actual representation as they exist before us, in their natural progress after their birth, as far as I am able, back to their origins, and try to seek the conditions out of which they spring. Thereupon I endeavor further to analyze those conditions, to see how far they are removable and how far they are avoidable."

WOODBURY (*FRANK*), *M.D.*,
Physician to the German Hospital, Philadelphia, late Chief Assist. to Med. Clinic, Jef. College Hospital, etc.

A HANDBOOK OF THE PRINCIPLES AND PRACTICE OF MEDICINE; for the use of Students and Practitioners. Based upon Husband's Handbook of Practice. In one neat volume, royal 12mo. (*Preparing.*)

FOTHERGILL (*J. MILNER*), *M.D. Edin., M.R.C.P. Lond.*,
Asst. Phys. to the West Lond. Hosp.: Asst. Phys. to the City of Lond. Hosp., etc.

THE PRACTITIONER'S HANDBOOK OF TREATMENT; Or, the Principles of Therapeutics. Second edition, revised and enlarged. In one very neat octavo volume of about 650 pages. Cloth, $4 00; very handsome half Russia, $5 50. (*Just Ready.*)

The call for a second edition of Dr. Fothergill's work has been met by the author with a revision performed in no perfunctory manner. The entire subject-matter has been submitted to a most careful and exhaustive scrutiny, and much new material been added, including articles on "The Functional Disturbances of the Liver," "The Means of Acting on the Respiratory Nerve Centres," "The Reflex Consequences of Ovarian Irritation," "When Not to Give Iron," "Artificial Digestion," etc., thus presenting a complete reflex of the existing condition of therapeutical science.

The junior members of the profession will find in it a work that should not only be read, but carefully studied. It will assist them in the proper selection and combination of therapeutical agents best adapted to each case and condition, and enable them to prescribe intelligently and successfully. To do full justice to a work of this scope and character will be impossible in a review of this kind. The book itself must be read to be fully appreciated. —*St. Louis Courier of Medicine*, Nov. 1880.

The author merits the thanks of every well-educated physician for his efforts toward rationalizing the treatment of diseases upon the scientific basis of physiology. Every chapter, every line, has the impress of a master hand, and while the work is thoroughly scientific in every particular, it presents to the thoughtful reader all the charms and beauties of a well-written novel. No physician can well afford to be without this valuable work, for its originality makes it fill a niche in medical literature hitherto vacant.—*Nashville Journ. of Med. and Surg.*, Oct. 1880.

To the great bulk of practitioners this work needs no introduction, being already well and favorably known to them. For that class, however, which is ever new, the educated, but inexperienced practitioner, to whom Dr. Fothergill specially addresses himself, and to whom probably he is most needful, we may state something of the general character of this work. Throughout the work, while room is left for difference of opinion in matters of detail, the main courses of treatment are so carefully founded on well-established principles, that no essential difference is felt to be possible. The closing chapter contains much concentrated worldly wisdom; and, if carefully read, digested, and assimilated, will, in many an emergency, stand the young medical man in good stead.—*Lond. Med. Record*, Oct. 12, 1880.

WATSON (*THOMAS*), *M.D., &c.*

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC. Delivered at King's College, London. A new American, from the Fifth revised and enlarged English edition. Edited, with additions, and several hundred illustrations, by HENRY HARTSHORNE, M.D., Professor of Hygiene in the University of Pennsylvania. In two large and handsome 8vo. vols. Cloth, $9 00; leather, $11 00. (*Lately Published.*)

HARTSHORNE (*HENRY*), *M.D.*,
Professor of Hygiene in the University of Pennsylvania

ESSENTIALS OF THE PRINCIPLES AND PRACTICE OF MEDICINE. A handy-book for Students and Practitioners. Fourth edition, revised and improved. With about one hundred illustrations. In one handsome royal 12mo. volume, of about 550 pages, cloth, $2 63; half bound, $2 88. (*Lately Issued.*)

REYNOLDS (J. RUSSELL), M.D.,

Prof. of the Principles and Practice of Medicine in Univ. College, London.

A SYSTEM OF MEDICINE WITH NOTES AND ADDITIONS BY HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Penna. In three large and handsome octavo volumes, containing 3052 closely printed double-columned pages, with numerous illustrations. *Sold only by subscription.* Price per vol., in cloth, $5.00; in sheep, $6.00: half Russia, raised bands, $6.50. Per set in cloth, $15; sheep, $18; half Russia, $19.50

VOLUME I. (*just ready*) contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.
VOLUME II. (*just ready*) contains DISEASES OF RESPIRATORY and CIRCULATORY SYSTEMS.
VOLUME III. (*just ready*) contains DISEASES OF THE DIGESTIVE and BLOOD GLANDULAR SYSTEMS, OF THE URINARY ORGANS, OF THE FEMALE REPRODUCTIVE SYSTEM, and OF THE CUTANEOUS SYSTEM.

Reynolds's SYSTEM OF MEDICINE, recently completed, has acquired, since the first appearance of the first volume, the well-deserved reputation of being the work in which modern British medicine is presented in its fullest and most practical form. This could scarce be otherwise in view of the fact that it is the result of the collaboration of the leading minds of the profession, each subject being treated by some gentleman who is regarded as its highest authority—as for instance, Diseases of the Bladder by Sir HENRY THOMPSON, Malpositions of the Uterus by GRAILY HEWITT, Insanity by HENRY MAUDSLEY, Consumption by J. HUGHES BENNETT, Diseases of the Spine by CHARLES BLAND RADCLIFFE, Pericarditis by FRANCIS SIBSON, Alcoholism by FRANCIS E. ANSTIE, Renal Affections by WILLIAM ROBERTS, Asthma by HYDE SALTER, Cerebral Affections by H. CHARLTON BASTIAN, Gout and Rheumatism by ALFRED BARING GARROD, Constitutional Syphilis by JONATHAN HUTCHINSON, Diseases of the Stomach by WILSON FOX, Diseases of the Skin by BALMANNO SQUIRE, Affections of the Larynx by MORELL MACKENZIE, Diseases of the Rectum by BLIZARD CURLING, Diabetes by LAUDER BRUNTON, Intestinal Diseases by JOHN SYER BRISTOWE, Catalepsy and Somnambulism by THOMAS KING CHAMBERS, Apoplexy by J. HUGHLINGS JACKSON, Angina Pectoris by Professor GAIRDNER, Emphysema of the Lungs by Sir WILLIAM JENNER, etc. etc. All the leading schools in Great Britain have contributed their best men in generous rivalry, to build up this monument of medical science. St. Bartholomew's, Guy's, St Thomas's, University College, St Mary's in London, while the Edinburgh, Glasgow, and Manchester schools are equally well represented, the Army Medical School at Netley, the military and naval services, and the public health boards. That a work conceived in such a spirit, and carried out under such auspices should prove an indispensable treasury of facts and experience, suited to the daily wants of the practitioner, was inevitable, and the success which it has enjoyed in England, and the reputation which it has acquired on this side of the Atlantic, have sealed it with the approbation of the two pre-eminently practical nations.

Its large size and high price having kept it beyond the reach of many practitioners in this country who desire to possess it, a demand has arisen for an edition at a price which shall render it accessible to all. To meet this demand the present edition has been undertaken. The five volumes and five thousand pages of the original have by the use of a smaller type and double columns, been compressed into three volumes of over three thousand pages, clearly and handsomely printed, and offered at a price which renders it one of the cheapest works ever presented to the American profession.

But not only is the American edition more convenient and lower priced than the English; it is also better and more complete. Some years having elapsed since the appearance of a portion of the work, additions are required to bring up the subjects to the existing condition of science. Some diseases, also, which are comparatively unimportant in England, require more elaborate treatment to adapt the articles devoted to them to the wants of the American physician; and there are points on which the received practice in this country differs from that adopted abroad. The supplying of these deficiencies has been undertaken by HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Pennsylvania, who has endeavored to render the work fully up to the day, and as useful to the American physician as it has proved to be to his English brethren. The number of illustrations has also been largely increased, and no effort spared to render the typographical execution unexceptionable in every respect.

Really too much praise can scarcely be given to this noble book. It is a cyclopædia of medicine written by some of the best men of Europe. It is full of useful information such as one finds frequent need of in one's daily work. As a book of reference it is invaluable. It is up with the times. It is clear and concentrated in style, and its form is worthy of its famous publisher.—*Louisville Med. News*, Jan. 31, 1880.

"Reynolds' System of Medicine" is justly considered the most popular work on the principles and practice of medicine in the English language. The contributors to this work are gentlemen of well-known reputation on both sides of the Atlantic. Each gentleman has striven to make his part of the work as practical as possible, and the information contained is such as is needed by the busy practitioner.—*St. Louis Med. and Surg. Journ.*, Jan. '80.

Dr. Hartshorne has made ample additions and revisions, all of which give increased value to the volume, and render it more useful to the American practitioner. There is no volume in English medical literature more valuable, and every purchaser will, on becoming familiar with it, congratulate himself on the possession of this vast storehouse of information, in regard to so many of the subjects with which he should be familiar.—*Gaillard's Med. Journ.*, Feb. 1880.

There is no medical work which we have in times past more frequently and fully consulted when perplexed by doubts as to treatment, or by having unusual or apparently inexplicable symptoms presented to us than "Reynolds' System of Medicine." Among its contributors are gentlemen who are as well known by reputation upon this side of the Atlantic as in Great Britain, and whose right to speak with authority upon the subjects about which they have written, is recognized the world over. They have evidently striven to make their essays as practical as possible, and while these are sufficiently full to entitle them to the name of monographs, they are not loaded down with such an amount of detail as to render them wearisome to the general reader. In a word, they contain just that kind of information which the busy practitioner frequently finds himself in need of. In order that any deficiencies may be supplied, the publishers have committed the preparation of the book for the press to Dr. Henry Hartshorne, whose judicious notes distributed throughout the volume afford abundant evidence of the thoroughness of the revision to which he has subjected it.—*Am. Jour. Med. Sciences*, Jan. 1880.

BARTHOLOW (ROBERTS), A.M., M.D., LL.D.

Prof. of Materia Medica and General Therapeutics in the Jeff. Med. Coll. of Phila., etc.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATION TO MEDICINE.

In one very handsome octavo volume of about 450 pages, with illustrations. (*In press.*)

The constantly increasing therapeutic use of electricity, and the absence of a concise guide suited to the wants of the general practitioner, have induced the author to prepare the present volume. His object has been to present the most advanced state of existing knowledge in a form divested of unnecessary technicalities, keeping constantly in view the practical needs of the student and physician.

As the volume is founded upon a course of lectures delivered in the Jefferson Medical College during 1880, its adaptation to its purpose is insured. Dr. Bartholow's power of lucid exposition is well known, and is particularly desirable in a subject such as this, treated from the standpoint of the general practitioner and not of the specialist.

FINLAYSON (JAMES), M.D.,

Physician and Lecturer on Clinical Medicine in the Glasgow Western Infirmary, etc.

CLINICAL DIAGNOSIS; A Handbook for Students and Practitioners of Medicine.

In one handsome 12mo. volume, of 546 pages, with 85 illustrations. Cloth, $2 63. (*Just Issued.*)

The book is an excellent one, clear, concise, convenient, practical. It is replete with the very knowledge the student needs when he quits the lecture-room and the laboratory for the ward and sick-room, and does not lack in information that will meet the wants of experienced and older men.—*Phila. Med. Times*, Jan. 4, 1879.

This is one of the really useful books. It is attractive from preface to the final page, and ought to be given a place on every office table, because it contains in a condensed form all that is valuable in semeiology and diagnostics to be found in bulkier volumes, and because in its arrangement and complete index, it is unusually convenient for quick reference in any emergency that may come upon the busy practitioner.—*N. C. Med. Journ.*, Jan. 1879.

MITCHELL (S. WEIR), M.D.,

Physician to Orthopædic Hospital and the Infirmary for Diseases of the Nervous System, etc. etc.

CLINICAL LECTURES ON THE NERVOUS DISEASES OF WOMEN.

In one very handsome 12mo. volume. (*Shortly.*)

HAMILTON (ALLAN McLANE), M.D.,

Attending Physician at the Hospital for Epileptics and Paralytics, Blackwell's Island, N.Y., and at the Out-Patients' Department of the New York Hospital.

NERVOUS DISEASES; THEIR DESCRIPTION AND TREATMENT.

In one handsome octavo volume of 512 pages, with 53 illus.; cloth, $3 50. (*Lately Issued.*)

CLINICAL OBSERVATIONS ON FUNCTIONAL NERVOUS DISORDERS. By C. HANDFIELD JONES, M.D., Physician to St. Mary's Hospital, &c. Second American Edition. In one handsome octavo volume of 348 pages, cloth, $3 25.

MORRIS (MALCOLM), M.D.,

Joint Lecturer on Dermatology, St. Mary's Hospital Med. School.

SKIN DISEASES, Including their Definitions, Symptoms, Diagnosis, Prognosis, Morbid Anatomy, and Treatment.

A Manual for Students and Practitioners. In one 12mo. volume of over 300 pages. With illustrations. Cloth, $1 75. (*Now Ready.*)

To physicians who would like to know something about skin diseases, so that when a patient presents himself for relief they can make a correct diagnosis and prescribe a rational treatment, we unhesitatingly recommend this little book of Dr. Morris. The affections of the skin are described in a terse, lucid manner, and their several characteristics so plainly set forth that diagnosis will be easy. The treatment in each case is such as the experience of the most eminent dermatologists advise.—*Cincinnati Medical News*, April, 1880.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that in the whole range of medical literature of a like scope, there is no book which for clearness of expression and methodical arrangement is better adapted to promote a rational conception of dermatology, a branch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine*, April, 1880.

The author of this manual has evidently a full and intimate acquaintance with the literature of dermatology, and with the most recent developments and appliances of cutaneous medicine. He has produced a plain, practical book, by aid of which, who so chooses may train his eye to the recognition of light but significant differences. The descriptions are neither too vague nor over-refined; the directions for treatment are clear and succinct.—*London Brain*, April, 1880.

The author has handled his subject in a clear and concise manner, and as a text-book to students his manual will be found useful.—*Medical and Surgical Reporter*, March 27, 1880.

The author's task has been well done and has produced one of the best recent works upon the difficult subject of which it treats; there is no work published which gives a better view of the elementary facts and principles of dermatology.—*New Orleans Medical and Surgical Journal*, April, 1880.

This excellent little book is the first work of a distinguished pupil of Jonathan Hutchinson; it recommends itself above all by its clearness, method and precision.—*Annales de Dermatologie et de Syphiligraphie, Paris*, 25 April, 1880.

FOX (TILBURY), M.D., F.R.C.P., and T. C. FOX, B.A., M.R.C.S.,

Physicians to the Department for Skin Diseases, University College Hospital.

EPITOME OF SKIN DISEASES, WITH FORMULÆ.

FOR STUDENTS AND PRACTITIONERS. Second edition, thoroughly revised and greatly enlarged. In one very handsome 12mo. volume of 216 pages. Cloth, $1 38. (*Just Issued.*)

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Hospital Med. College, N. Y.

A MANUAL OF PERCUSSION AND AUSCULTATION; of the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism. Second edition. In one handsome royal 12mo. volume: cloth, $1 63. (*Just Ready.*)

Prof. Flint is so well known as a medical teacher and writer that it seems superfluous to state that the subject has been treated in a thorough and systematic manner. In revising it for a second edition the author has confined himself to such additions as seem likely to render it more useful, not only to students engaged in the practical study of the subject, but also to practitioners as a handbook for ready reference, and we do not hesitate in saying that it would prove a valuable addition to every physician's library.—*Med. and Surg. Reporter*, March 18 1880.

The little work before us has already become a standard one, and has become extensively adopted as a text-book. There is certainly none better. It contains the substance of the lessons which the author has for many years given, in connection with practical instruction in auscultation and percussion, to private classes, composed of medical students and practitioners.—*Cincinnati Med. News*, Feb. 1880.

BY THE SAME AUTHOR.

PHTHISIS: ITS MORBID ANATOMY, ETIOLOGY, SYMPTOMATIC EVENTS AND COMPLICATIONS, FATALITY AND PROGNOSIS, TREATMENT AND PHYSICAL DIAGNOSIS; in a series of Clinical Studies. By AUSTIN FLINT, M.D., Prof. of the Principles and Practice of Medicine in Bellevue Hospital Med. College, New York. In one handsome octavo volume: $3 50. (*Lately Issued.*)

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DIAGNOSIS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART. Second revised and enlarged edition. In one octavo volume of 550 pages, with a plate, cloth, $4.

Dr. Flint chose a difficul subject for his researches, and has shown remarkable powers of observation and reflection, as well as great industry, in his treatment of it. His book must be considered the fullest and clearest practical treatise on those subjects, and should be in the hands of all practitioners and students. It is a credit to American medical literature.—*Amer. Journ. of the Med. Sciences*, July, 1860.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE PHYSICAL EXPLORATION OF THE CHEST AND THE DIAGNOSIS OF DISEASES AFFECTING THE RESPIRATORY ORGANS. Second and revised edition. In one handsome octavo volume of 595 pages, cloth, $4 50.

BROWN (LENNOX), F.R.C.S. Ed.,

Senior Surgeon to the Central London Throat and Ear Hospital, etc.

THE THROAT AND ITS DISEASES. With one hundred Typical Illustrations in colors, and fifty wood engravings, designed and executed by the author. In one very handsome imperial octavo volume of 351 pages; cloth, $5 00. (*Just Ready.*)

SEILER (CARL), M.D.,

Lecturer on Laryngoscopy at the Univ. of Penna., Chief of the Throat Dispensary at the Univ. Hospital, Phila., etc.

HANDBOOK OF DIAGNOSIS AND TREATMENT OF DISEASES OF THE THROAT AND NASAL CAVITIES. In one handsome royal 12mo. volume, of 156 pages, with 35 illustrations; cloth, $1. (*Just Ready.*)

We most heartily commend this book as showing sound judgment in practice, and perfect familiarity with the literature of the speciality it so ably epitomizes.—*Philada. Med. Times*, July 5, 1879.

A convenient little handbook, clear, concise and accurate in its method, and admirably fulfilling its purpose of bringing the subject of which it treats within the comprehension of the general practitioner.—*N. C. Med. Jour.*, June, 1879.

WILLIAMS'S PULMONARY CONSUMPTION; its Nature, Varieties, and Treatment. With an Analysis of One Thousand Cases to exemplify its duration. In one neat octavo volume of about 350 pages; cloth, $2 50.

SLADE ON DIPHTHERIA; its Nature and Treatment, with an account of the History of its Prevalence in various Countries. Second and revised edition. In one neat royal 12mo. volume, cloth, $1 25.

WALSHE ON THE DISEASES OF THE HEART AND GREAT VESSELS. Third American Edition. In 1 vol. 8vo., 420 pp., cloth, $3 00.

CHAMBERS'S MANUAL OF DIET AND REGIMEN IN HEALTH AND SICKNESS. In one handsome octavo volume. Cloth, $2 75.

LA ROCHE ON PNEUMONIA. 1 vol. 8vo., cloth, of 500 pages Price, $3 00.

WILSON'S STUDENT'S BOOK OF CUTANEOUS MEDICINE and DISEASES OF THE SKIN. In one very handsome royal 12mo volume. $3 50.

FULLER ON DISEASES OF THE LUNGS AND AIR-PASSAGES. Their Pathology, Physical Diagnosis, Symptoms, and Treatment. From the second and revised English edition. In one handsome octavo volume of about 500 pages: cloth, $3 50.

SMITH ON CONSUMPTION; ITS EARLY AND REMEDIABLE STAGES. 1 vol. 8vo., pp. 254. $2 25.

BASHAM ON RENAL DISEASES: a Clinical Guide to their Diagnosis and Treatment. With Illustrations In one 12mo. vol. of 304 pages, cloth, $2 00.

LECTURES ON THE STUDY OF FEVER. By A. HUDSON, M.D., M.R.I.A., Physician to the Meath Hospital. In one vol. 8vo., cloth, $2 50.

A TREATISE ON FEVER. By ROBERT D. LYONS, K.C.C. In one octavo volume of 362 pages, cloth $2 25.

HILLIER'S HANDBOOK OF SKIN DISEASES, for Students and Practitioners. Second Am Ed In one royal 12mo. vol. of 338 pp. With illustrations. Cloth, $2 25.

BUMSTEAD (FREEMAN J.), M.D., LL.D.,

Professor of Venereal Diseases at the Col. of Phys. and Surg., New York, &c.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES.

Including the results of recent investigations upon the subject. Fourth edition, revised and largely rewritten with the co-operation of R. W. Taylor, M.D., of New York, Prof. of Dermatology in the Univ. of Vt. In one large and handsome octavo volume of 835 pages, with 138 illustrations. Cloth, $4 75; leather, $5 75; half Russia, $6 25. (*Now Ready.*)

This work, on its first appearance, immediately took the position of a standard authority on its subject wherever the language is spoken, and the success of an Italian translation shows that it is regarded with equal favor on the Continent of Europe. In repeated editions the author labored sedulously to render it more worthy of its reputation, and in the present revision no pains have been spared to perfect it as far as possible. Several years having elapsed since the publication of the third edition, much material has been accumulated during the interval by the industry of syphilologists, and new views have been enunciated. All this so far as confirmed by observation and experience has been incorporated; many portions of the volume been rewritten, the series of illustrations has been enlarged and improved, and the whole may be regarded rather as a new work than as a new edition. It is confidently presented as fully on a level with the most advanced condition of syphilology, and as a work to which the practitioner may refer with the certainty of finding clearly and succinctly set forth whatever falls within the scope of such a treatise.

We have to congratulate our countrymen upon the truly valuable addition which they have made to American literature. The careful estimate of the value of the volume, which we have made, justifies us in declaring that this is the best treatise on venereal diseases in the English language, and, we might add, if there is a better in any other tongue we cannot name it; there are certainly no books in which the student or the general practitioner can find such an excellent *résumé* of the literature of any topic, and such practical suggestions regarding the treatment of the various complications of every venereal disease. We take pleasure in repeating that we believe this to be the best treatise on venereal disease in the English language, and we congratulate the authors upon their brilliant addition to American medical literature.—*Chicago Med. Journal and Examiner*, February, 1880.

It is, without exception, the most valuable single work on all branches of the subject of which it treats in any language. The pathology is sound, the work is, at the same time, in the highest degree practical, and the hints that he will get from it for the management of any one case, at all obscure or obstinate, will more than repay him for the outlay.—*Archives of Medicine*, April, 1880.

This now classical work on venereal disease comes to us in its fourth edition rewritten, enlarged, and materially improved in every way. Dr. Taylor, as we had every reason to expect, has performed this part of his work with unusual excellence. We feel that what has been written has done but scanty justice to the merits of this truly great treatise.—*St. Louis Courier of Medicine*, Feb. 1880

We find that we have here practically a new book—that the statement of the title page, as to the fact that it has been largely rewritten, is a sufficiently modest announcement for the important changes in the text. After a thorough examination of the present edition, we can assert confidently that the enormous labor we have described has been here most faithfully and conscientiously performed.—*Amer. Journ. Med. Sci.*, Jan 1880.

It is one of the best general treatises on venereal diseases with which we are acquainted, and is especially to be recommended as a guide to the treatment of syphilis.—*London Practitioner*, March, 1880.

CULLERIER (A.), *Surgeon to the Hôpital du Midi.* and BUMSTEAD (FREEMAN J.), *Professor of Venereal Diseases in the College of Physicians and Surgeons, N. Y.*

AN ATLAS OF VENEREAL DISEASES.

Translated and Edited by FREEMAN J. BUMSTEAD. In one large imperial 4to, volume of 328 pages, double-columns, with 26 plates, containing about 150 figures, beautifully colored, many of them the size of life; strongly bound in cloth, $17 00; also, in five parts, stout wrappers, at $3 per part.

Anticipating a very large sale for this work, it is offered at the very low price of THREE DOLLARS a Part, thus placing it within the reach of all who are interested in this department of practice. Gentlemen desiring early impressions of the plates would do well to order it without delay. A specimen of the plates and text sent free by mail, on receipt of 25 cents.

LEE'S LECTURES ON SYPHILIS AND SOME FORMS OF LOCAL DISEASE AFFECTING PRINCIPALLY THE ORGANS OF GENERATION. In one handsome octavo volume; cloth, $2 25.

HILL ON SYPHILIS AND LOCAL CONTAGIOUS DISORDERS. In one handsome octavo volume; cloth $3 25.

WEST (CHARLES), M.D.,

Physician to the Hospital for Sick Children, London, &c.

LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD.

Fifth American from the sixth revised and enlarged English edition. In one large and handsome octavo volume of 678 pages. Cloth, $4 50; leather, $5 50. (*Lately Issued.*)

BY THE SAME AUTHOR. (*Lately Issued.*)

ON SOME DISORDERS OF THE NERVOUS SYSTEM IN CHILDHOOD;

being the Lumleian Lectures delivered at the Royal College of Physicians of London, in March, 1871. In one volume small 12mo, cloth, $1 50.

BY THE SAME AUTHOR.

LECTURES ON THE DISEASES OF WOMEN.

Third American, from the Third London edition. In one neat octavo volume of about 550 pages, cloth, $3 75; leather, $4 75.

SMITH (J. LEWIS), M.D.,

Clinical Professor of Diseases of Children in the Bellevue Hospital Med. College, N.Y.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN.

Fourth Edition, revised and enlarged. In one handsome octavo volume of about 750 pages, with illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

The very marked favor with which this work has been received wherever the English language is spoken, has stimulated the author, in the preparation of the Fourth Edition, to spare no pains in the endeavor to render it worthy in every respect of a continuance of professional confidence. Many portions of the volume have been rewritten, and much new matter introduced, but by an earnest effort at condensation, the size of the work has not been materially increased.

In the period which has elapsed since the third edition of the work, so extensive have been the advances that whole chapters required to be rewritten, and hardly a page could pass without some material correction or addition. This labor has occupied the writer closely, and he has performed it conscientiously, so that the book may be considered a faithful portraiture of an exceptionally wide clinical experience in infantile diseases, corrected by a careful study of the recent literature of the subject.—*Med. and Surg. Reporter*, April 5, 1879.

It is scarcely necessary for us to say the work before us is a standard work upon diseases of children, and that no work has a higher standing than it upon these affections. In consequence of its thorough revision, the work has been made of more value than ever, and may be regarded as fully abreast of the times. We cordially commend it to students and physicians. There is no better work in the language on diseases of children.—*Cincinnati Med. News*, March, 1879.

The author has evidently determined that it shall not lose ground in the esteem of the profession for want of the latest knowledge on that important department of medicine. He has accordingly incorporated in the present edition the useful and practical results of the latest study and experience, both American and foreign, especially those bearing on therapeutics. Altogether the book has been greatly improved, while it has not been greatly increased in size.—*New York Medical Journal*, June, 1879.

This excellent work is so well known that an extended notice at this time would be superfluous. The author has taken advantage of the demand for another new edition to revise in a most careful manner the entire book; and the numerous corrections and additions evince a determination on his part to keep fully abreast with the rapid progress that is being made in the knowledge and treatment of children's diseases. By the adoption of a somewhat closer type, an increase in size of only thirty pages has been necessitated by the new subject matter introduced.—*Boston Med. and Surg. Jour.*, May 29, 1879.

Probably no other work ever published in this country upon a medical subject has reached such a height of popularity as has this well-known treatise. As a text and reference-book it is pre-eminently the authority upon diseases of children. It stands deservedly higher in the estimation of the profession than any other work upon the same subject.—*Nashville Journ. of Med. and Surg.*, May, 1879.

SWAYNE (JOSEPH GRIFFITHS), M.D.,

Physician-Accoucheur to the British General Hospital, &c.

OBSTETRIC APHORISMS FOR THE USE OF STUDENTS COMMENCING MIDWIFERY PRACTICE.

Second American, from the Fifth and Revised London Edition, with Additions by E. R. HUTCHINS, M.D. With Illustrations. In one neat 12mo. volume. Cloth, $1 25. (*Lately Issued.*)

*** See p. 3 of this Catalogue for the terms on which this work is offered as a premium to subscribers to the AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

CHURCHILL ON THE PUERPERAL FEVER AND OTHER DISEASES PECULIAR TO WOMEN. 1 vol. 8vo., pp. 460, cloth. $2 50.

DEWEES'S TREATISE ON THE DISEASES OF FEMALES. With illustrations. Eleventh Edition with the Author's last improvements and corrections. In one octavo volume of 536 pages, with plates, cloth. $3 00.

MEIGS ON THE NATURE, SIGNS, AND TREATMENT OF CHILDBED FEVER. 1 vol. 8vo., pp. 365, cloth. $1 00.

ASHWELL'S PRACTICAL TREATISE ON THE DISEASES PECULIAR TO WOMEN. Third American, from the Third and revised London edition. 1 vol. 8vo., pp. 528, cloth. $3 50.

HODGE (HUGH L.), M.D.,

Emeritus Professor of Obstetrics, &c., in the University of Pennsylvania.

ON DISEASES PECULIAR TO WOMEN; including Displacements of the Uterus.

With original illustrations. Second edition, revised and enlarged. In one beautifully printed octavo volume of 581 pages, cloth, $4 50.

CHURCHILL (FLEETWOOD), M.D., M.R.I.A.

ON THE THEORY AND PRACTICE OF MIDWIFERY.

A new American from the fourth revised and enlarged London edition. With notes and additions by D. FRANCIS CONDIE, M.D., author of a Practical Treatise on the Diseases of Children, &c. With one hundred and ninety-four illustrations. In one very handsome octavo volume of nearly 700 large pages. Cloth, $4 00; leather, $5 00.

MONTGOMERY'S EXPOSITION OF THE SIGNS AND SYMPTOMS OF PREGNANCY. With two exquisite colored plates, and numerous wood-cuts In 1 vol. 8vo., of nearly 600 pp., cloth, $6 75

CONDIE'S PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Sixth edition, revised and augmented. In one large octavo volume of nearly 800 closely-printed pages, cloth, $5 25; leather $6 25.

RIGBY'S SYSTEM OF MIDWIFERY. With notes and Additional Illustrations. Second American edition One volume octavo, cloth, 429 pages, $2 50.

SMITH'S PRACTICAL TREATISE ON THE WASTING DISEASES OF INFANCY AND CHILDHOOD. Second American, from the second revised and enlarged English edition. In one handsome octavo volume, cloth, $2 50.

THOMAS (T. GAILLARD), M.D.,

Professor of Obstetrics, &c., in the College of Physicians and Surgeons, N. Y., &c.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN.

Fifth edition, thoroughly revised and rewritten. In one large and handsome octavo volume of over 800 pages, with 266 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50. (*Just Ready.*)

The author has taken advantage of the opportunity afforded by the call for a new edition of this work to render it worthy a continuance of the very remarkable favor with which it has been received. Every portion of the work has been carefully revised, very much of it has been rewritten, and additions and alterations introduced wherever the advance of science and the increased experience of the author have shown them desirable. At the same time special care has been exercised to avoid undue increase in the size of the volume. To accommodate the numerous additions a more condensed but very clear letter has been used, notwithstanding which, the number of pages has been increased by more than fifty. The series of illustrations has been extensively changed; many which seemed to be superfluous have been omitted, and a large number of new and superior drawings have been inserted. In its improved form, therefore, it is hoped that the volume will maintain the character it has acquired of a standard authority on every detail of its important subject.

An examination of the work will satisfy that it is one of great merit. It is not a mere compilation from other works, but is the fruit of the ripe thought, sound judgment, and critical observations of a learned, scientific man. It is a treasury of knowledge of the department of medicine to which it is devoted. In its present revised state it certainly holds a foremost position as a gynæcological work, and will continue to be regarded as a standard authority.—*Cincinnati Med. News*, Dec. 1880.

This work needs no introduction to any of the civilized nations of the world. The edition before us adds to the strength of former volumes. With the wisdom of a master teacher he here gives the results that, in his judgment, are most trustworthy at the present time. In its own place it has no rival, because the author is the best teacher on this subject to the masses of the profession. As hitherto this work will be the text-book on diseases of women. We only wish that in other branches of medicine as capable teachers could be found to write our text-books.—*Detroit Lancet*, Jan. 1881.

Since its first appearance, twelve years ago, until the present day, it has held a position of high regard, and is generally conceded to be one of the most practical and trustworthy volumes yet presented to the physician and student in the department of gynæcology. The work embodies not only its author's large experience, but reflects his careful study among other authorities in his branch, both at home and abroad. Dr. Thomas is an able and conscientious teacher. His writings convey his meaning in the same practical and instructive manner. The last edition of this work is fresh from his pen, with decided changes and improvements over former editions. His book presents generally accepted facts, and as a guide to the student is more useful and reliable than any work in the language on diseases of women. This last edition will add new laurels to those already won.—*Md. Med. Journ.*, Nov. 15, 1880.

It has been enlarged and carefully revised. The author has brought it fully abreast with the times, and as the wave of gynæcological progression has been widespread and rapid during the twelve years that have elapsed since the issue of the first edition, one can conceive of the great improvement this edition must be upon the earlier. It is a condensed encyclopædia of gynæcological medicine. The style of arrangement, the masterly manner in which each subject is treated, and the honest convictions derived from probably the largest clinical experience in that specialty of any in this country, all serve to commend it in the highest terms to the practitioner.—*Nashville Journ. of Med. and Surg.*, Jan. 1881.

BARNES (ROBERT), M.D., F.R.C.P.,

Obstetric Physician to St. Thomas's Hospital, &c.

A CLINICAL EXPOSITION OF THE MEDICAL AND SURGICAL DISEASES OF WOMEN.

Second American, from the Second Enlarged and Revised English Edition. In one handsome octavo volume, of 784 pages, with 181 illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Issued.*)

Dr Barnes stands at the head of his profession in the old country, and it requires but scant scrutiny of his book to show that it has been sketched by a master. It is plain, practical common sense; shows very deep research without being pedantic; is eminently calculated to inspire enthusiasm without inculcating rashness; points out the dangers to be avoided as well as the success to be achieved in the various operations connected with this branch of medicine; and will do much to smooth the rugged path of the young gynæcologist and relieve the perplexity of the man of mature years.—*Canadian Journ. of Med. Science*, Nov. 1878.

We pity the doctor who, having any considerable practice in diseases of women, has no copy of "Barnes" for daily consultation and instruction. It is at once a book of great learning, research, and individual experience, and at the same time eminently practical. That it has been appreciated by the profession, both in Great Britain and in this country, is shown by the second edition following so soon upon the first.—*Am. Practitioner*, Nov. 1878.

Dr. Barnes's work is one of a practical character, largely illustrated from cases in his own experience, but by no means confined to such, as will be learned from the fact that he quotes from no less than 628 medical authors in numerous countries. Coming from such an author, it is not necessary to say that the work is a valuable one, and should be largely consulted by the profession.—*Am. Supp. Obstetrical Journ. Gt. Britain and Ireland*, Oct. 1878.

No other gynæcological work holds a higher position, having become an authority everywhere in diseases of women. The work has been brought fully abreast of present knowledge. Every practitioner of medicine should have it upon the shelves of his library, and the student will find it a superior text-book.—*Cincinnati Med. News*, Oct. 1878.

This second revised edition, of course, deserves all the commendation given to its predecessor, with the additional one that it appears to include all or nearly all the additions to our knowledge of its subject that have been made since the appearance of the first edition. The American references are, for an English work, especially full and appreciative, and we can cordially recommend the volume to American readers.—*Journ. of Nervous and Mental Disease*, Oct. 1878.

This second edition of Dr. Barnes's great work comes to us containing many additions and improvements which bring it up to date in every feature. The excellences of the work are too well known to require enumeration, and we hazard the prophecy that they will for many years maintain its high position as a standard text-book and guide-book for students and practitioners.—*N. O. Med. Journ.*, Oct. 1878.

EMMET (*THOMAS ADDIS*), *M.D.*,

Surgeon to the Woman's Hospital, New York, etc.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the use of Students and Practitioners of Medicine. Second Edition. Thoroughly Revised. In one large and very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

PREFACE TO THE SECOND EDITION.

The unusually rapid exhaustion of a large edition of this work, while flattering to the author as an evidence that his labors have proved acceptable, has in a great measure heightened his sense of responsibility. He has therefore endeavored to take full advantage of the opportunity afforded to him for its revision. Every page has received his earnest scrutiny; the criticisms of his reviewers have been carefully weighed; and while no marked increase has been made in the size of the volume, several portions have been rewritten, and much new matter has been added. In this minute and thorough revision, the labor involved has been much greater than is perhaps apparent in the results, but it has been cheerfully expended in the hope of rendering the work more worthy of the favor which has been accorded to it by the profession.

In no country of the world has gynæcology received more attention than in America. It is, then, with a feeling of pleasure that we welcome a work on diseases of women from so eminent a gynæcologist as Dr. Emmet, and the work is essentially clinical, and leaves a strong impress of the author's individuality. To criticise, with the care it merits, the book throughout, would demand far more space than is at our command. In parting, we can say that the work teems with original ideas, fresh and valuable methods of practice, and is written in a clear and elegant style, worthy of the literary reputation of the country of Longfellow and Oliver Wendell Holmes.—*Brit. Med. Journ.* Feb 21, 1880.

No gynæcological treatise has appeared which contains an equal amount of original and useful matter; nor does the medical and surgical history of America include a book more novel and useful. The tabular and statistical information which it contains is marvellous, both in quantity and accuracy, and cannot be otherwise than invaluable to future investigators. It is a work which demands not careless reading but profound study. Its value as a contribution to gynæcology is, perhaps, greater than that of all previous literature on the subject combined.—*Chicago Med Gaz.*, April 5, 1880

The wide reputation of the author makes its publication an event in the gynæcological world; and a glance through its pages shows that it is a work to be studied with care. . . . It must always be a work to be carefully studied and frequently consulted by those who practise this branch of our profession.—*Lond. Med. Times and Gaz.*, Jan. 10, 1880.

The character of the work is too well known to require extended notice—suffice it to say that no recent work upon any subject has attained such great popularity so rapidly. As a work of general reference upon the subject of Diseases of Women it is invaluable. As a record of the largest clinical experience and observation it has no equal. No physician who pretends to keep up with the advances of this department of medicine can afford to be without it.—*Nashville Journ. of Medicine and Surgery*, May, 1880.

DUNCAN (*J. MATTHEWS*), *M.D., LL.D., F.R.S.E., etc.*

CLINICAL LECTURES ON THE DISEASES OF WOMEN, Delivered in Saint Bartholomew's Hospital. In one very neat octavo volume of 173 pages. Cloth, $1 50. (*Just Ready.*)

They are in every way worthy of their author; indeed, we look upon them as among the most valuable of his contributions. They are all upon matters of great interest to the general practitioner. Some of them deal with subjects that are not, as a rule, adequately handled in the text-books; others of them, while bearing upon topics that are usually treated of at length in such works, yet bear such a stamp of individuality that, if widely read, as they certainly deserve to be, they cannot fail to exert a wholesome restraint upon the undue eagerness with which many young physicians seem bent upon following the wild teachings which so infest the gynæcology of the present day.—*N. Y. Med. Journ.*, March, 1880.

The author is a remarkably clear lecturer, and his discussion of symptoms and treatment is full and suggestive. It will be a work which will not fail to be read with benefit by practitioners as well as by students.—*Phila. Med. and Surg. Reporter*, Feb. 7, 1880.

We have read this book with a great deal of pleasure. It is full of good things. The hints on pathology and treatment scattered through the book are sound, trustworthy, and of great value. A healthy scepticism, a large experience, and a clear judgment are everywhere manifest. Instead of bristling with advice of doubtful value and unsound character, the book is in every respect a safe guide.—*The London Lancet*, Jan. 21, 1880.

RAMSBOTHAM (*FRANCIS H.*), *M.D.*

THE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY, in reference to the Process of Parturition. A new and enlarged edition, thoroughly revised by the author. With additions by W. V. KEATING, M. D., Professor of Obstetrics, &c., in the Jefferson Medical College, Philadelphia. In one large and handsome imperial octavo volume of 650 pages, strongly bound in leather, with raised bands; with sixty-four beautiful plates, and numerous wood-cuts in the text, containing in all nearly 200 large and beautiful figures. $7 00

WINCKEL (*F.*),

Professor and Director of the Gynæcological Clinic in the University of Rostock.

A COMPLETE TREATISE ON THE PATHOLOGY AND TREATMENT OF CHILDBED, for Students and Practitioners. Translated, with the consent of the author, from the Second German Edition, by JAMES READ CHADWICK, M.D. In one octavo volume. Cloth, $4 00. (*Lately Issued.*)

TANNER (*THOMAS H.*), *M.D.*

ON THE SIGNS AND DISEASES OF PREGNANCY. First American from the Second and Enlarged English Edition. With four colored plates and illustrations on wood. In one handsome octavo volume of about 500 pages, cloth, $4 25.

LEISHMAN (*WILLIAM*), *M.D.*,

Regius Professor of Midwifery in the University of Glasgow, &c.

A SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE.

Third American edition, revised by the Author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Philadelphia Hospital, &c. In one large and very handsome octavo volume, of 733 pages, with over two hundred illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready.*)

Few works on this subject have met with as great a demand as this one appears to have. To judge by the frequency with which its author's views are quoted, and its statements referred to in obstetrical literature, one would judge that there are few physicians devoting much attention to obstetrics who are without it. The author is evidently a man of ripe experience and conservative views, and in no branch of medicine are these more valuable than in this.—*New Remedies*, Jan. 1880.

We gladly welcome the new edition of this excellent text-book of midwifery. The former editions have been most favorably received by the profession on both sides of the Atlantic. In the preparation of the present edition the author has made such alterations as the progress of obstetrical science seems to require, and we cannot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

To the American student the work before us must prove admirably adapted, complete in all its parts, essentially modern in its teachings and with demonstrations noted for clearness and precision, it will gain in favor and be recognized as a work of standard merit. The work cannot fail to be popular, and is cordially recommended.—*N. O. Med. and Surg. Journ.*, March, 1880.

Leishman's is certainly one of the best systematic works on midwifery. It is very complete in all the parts essential for such a treatise. To practitioners and students it is to be strongly recommended as a safe and reliable guide to the modern practice of midwifery.—*Canada Med. and Surg. Journal*, March, 1880.

This is a book of well-established reputation, both in England and America. The present edition has been revised with care by the distinguished author, and supplied with such additions and emendations as the rapid advances in obstetrical science demand. *Pacific Med. and Surg. Journ.*, May, 1880.

The book is greatly improved, and as such will be welcomed by those who are trying to keep posted in the rapid advances which are being made in the study of obstetrics.—*Boston Med. and Surg. Journ.*, Nov 27, 1879.

This work is a thoroughly good one, and is well adapted to the requirements of the practical obstetrician. It is something more than a compend designed for the medical student: it is a book to be studied by the practitioner, and it will seldom disappoint him. It is of convenient size, clearly written, and eminently practical. As such, we heartily commend it to our readers.—*St. Louis Clin. Record*, Jan. 1880.

We are glad to call the attention of our readers to this new edition of Dr. Leishman's well-known work, which has already established itself in general favor both in this country and in America. In noticing this third edition we need only direct attention to the differences between it and its predecessor. Although carefully revised throughout, with not a few additions in various places, the net enlargement amounts only to a few pages.—*Glasgow Med. Journ.*, Jan. 1880.

Leishman's is certainly one of the best systematic works on midwifery. It is very complete in all the parts essential for such a treatise. To practitioners and students it is to be strongly recommended as a safe and reliable guide to the modern practice of midwifery.—*Canada Med. and Surg. Journal*, March, 1880.

It has been well and carefully written. The views of the author are broad and liberal, and indicate a well balanced judgment and matured mind. We observe no spirit of dogmatism, but the earnest teaching of the thoughtful observer and lover of true science. Take the volume as a whole, and it has few equals.—*Mid. Med. Journ.*, Feb. 1880.

Dr. Leishman is too well known to the profession, not only that but to the student who is about to enter the profession, to need any introduction. Of his work, we need but say that it is a standard, sound and practical.—*St. Louis Courier of Med.*, Jan. 1880.

PARRY (*JOHN S.*), *M.D.*,

Obstetrician to the Philadelphia Hospital, Vice-Pres. of the Obstet. Society of Philadelphia.

EXTRA-UTERINE PREGNANCY: ITS CLINICAL HISTORY, DIAGNOSIS, PROGNOSIS, AND TREATMENT.

In one handsome octavo volume. Cloth, $2 50. (*Lately Issued.*)

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Midwifery, &c., in the University of Pennsylvania, &c.

THE PRINCIPLES AND PRACTICE OF OBSTETRICS.

Illustrated with large lithographic plates containing one hundred and fifty-nine figures from original photographs, and with numerous wood-cuts. In one large and beautifully printed quarto volume of 550 double-columned pages, strongly bound in cloth, $14.

The work of Dr. Hodge is something more than a simple presentation of his particular views in the department of Obstetrics; it is something more than an ordinary treatise on midwifery; it is, in fact, a cyclopædia of midwifery. He has aimed to embody in a single volume the whole science and art of Obstetrics. An elaborate text is combined with accurate and varied pictorial illustrations, so that no fact or principle is left unstated or unexplained. —*Am. Med. Times*, Sept. 3, 1864.

*** Specimens of the plates and letter-press will be forwarded to any address, free by mail on receipt of six cents in postage stamps.

CHADWICK (*JAMES R.*), *A.M., M.D.*

A MANUAL OF THE DISEASES PECULIAR TO WOMEN.

In one neat volume, royal 12mo., with illustrations. (*Preparing.*)

PLAYFAIR (W. S.), M.D., F.R.C.P.,

Professor of Obstetric Medicine in King's College, etc. etc.

A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY.

Third American edition, revised by the author. Edited, with additions, by ROBERT P. HARRIS, M.D. In one handsome octavo volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, $5 50. (*Just Ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

The second American edition of my work on Midwifery being exhausted before the corresponding English edition, I cannot better show my appreciation of the kind reception my book has received in the United States than by acceding to the publisher's request that I should myself undertake the issue of a third edition. As little more than a year has elapsed since the second edition was issued, there are naturally not many changes to make, but I have, nevertheless, subjected the entire work to careful revision, and introduced into it a notice of most of the more important recent additions to obstetric science. To the operation of gastro-elytrotomy—formerly described along with the Cæsarean section—I have now devoted a separate chapter. The editor of the Second American edition, Dr. Harris, enriched it with many valuable notes, of which, it will be observed, I have freely availed myself.

The medical profession has now the opportunity of adding to their stock of standard medical works one of the best volumes on midwifery ever published. The subject is taken up with a master hand. The part devoted to labor in all its various presentations, the management and results, is admirably arranged, and the views entertained will be found essentially modern, and the opinions expressed trustworthy. The work abounds with plates, illustrating various obstetrical positions; they are admirably wrought, and afford great assistance to the student.—*N. O. Med. and Surg. Journ.*, March, 1880.

If inquired of by a medical student what work on obstetrics we should recommend for him, as *par excellence*, we would undoubtedly advise him to choose Playfair's. It is of convenient size, but what is of chief importance, its treatment of the various subjects is concise and plain. While the discussions and descriptions are sufficiently elaborate to render a very intelligent idea of them, yet all details not necessary for a full understanding of the subject are omitted.—*Cincinnati Med. News*, Jan. 1880.

The rapidity with which one edition of this work follows another is proof alike of its excellence and of the estimate that the profession has formed of it. It is indeed so well known and so highly valued that nothing need be said of it as a whole. All things considered, we regard this treatise as the very best on Midwifery in the English language.—*N. Y. Medical Journal*, May, 1880

It certainly is an admirable exposition of the Science and Practice of Midwifery. Of course the additions made by the American editor, Dr. R. P. Harris, who never utters an idle word, and whose studious researches in some special departments of obstetrics are so well known to the profession, are of great value.—*The American Practitioner*, April, 1880.

BARNES (FANCOURT), M.D.,

Physician to the General Lying-in Hospital, London.

A MANUAL OF MIDWIFERY FOR MIDWIVES AND MEDICAL STUDENTS. With 50 illustrations. In one neat royal 12mo. volume of 200 pages; cloth, $1 25. (*Now Ready.*)

The book is written in plain, and as far as possible in unechnical language. Any intelligent midwife or medical student can easily comprehend the directions. It will undoubtedly fill a want, and will be popular with those for whom it has been prepared. The examining questions at the back will be found very useful.—*Cincinnati Med. News*, Aug. 1879.

STIMSON (LEWIS A.), A.M., M.D.,

Surgeon to the Presbyterian Hospital.

A MANUAL OF OPERATIVE SURGERY. In one very handsome royal 12mo. volume of about 500 pages, with 382 illustrations; cloth, $2 50. (*Just Issued.*)

The work before us is a well printed, profusely illustrated manual of over four hundred and seventy pages. The novice, by a perusal of the work, will gain a good idea of the general domain of operative surgery, while the practical surgeon has presented to him within a very concise and intelligible form the latest and most approved selections of operative procedure. The precision and conciseness with which the different operations are described enable the author to compress an immense amount of practical information in a very small compass.—*N. Y. Medical Record*, Aug. 3, 1878.

This volume is devoted entirely to operative surgery, and is intended to familiarize the student with the details of operations and the different modes of performing them. The work is handsomely illustrated, and the descriptions are clear and well drawn. It is a clever and useful volume; every student should possess one The preparation of this work does away with the necessity of pondering over larger works on surgery for descriptions of operations, as it presents in a nut-shell just what is wanted by the surgeon without an elaborate search to find it.—*Md. Med Journal*, Aug. 1878.

The author's conciseness and the repleteness of the work with valuable illustrations entitle it to be classed with the text-books for students of operative surgery, and as one of reference to the practitioner. —*Cincinnati Lancet and Clinic*, July 27, 1878.

SKEY'S OPERATIVE SURGERY. In 1 vol. 8vo. cl., of 650 pages; with about 100 wood-cuts $3 25

COOPER'S LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY. In 1 vol. 8vo cl'h, 750 p. $2.

GIBSON'S INSTITUTES AND PRACTICE OF SURGERY. Eighth edition, improved and altered. With thirty-four plates. In two handsome octavo volumes, about 1060 pp., leather, raised bands, $6 50.

THE PRINCIPLES AND PRACTICE OF SURGERY. By WILLIAM PIRRIE, F.R.S.E., Professor of Surgery in the University of Aberdeen. Edited by JOHN NEILL, M.D., Professor of Surgery in the Penna. Medical College, Surgeon to the Pennsylvania Hospital, &c. In one very handsome octavo vol. of 780 pages, with 316 illustrations, cloth, $3 75.

MILLER'S PRINCIPLES OF SURGERY. Fourth American, from the Third Edinburgh Edition. In one large 8vo. vol. of 700 pages, with 340 illustrations, cloth, $3 75.

MILLER'S PRACTICE OF SURGERY. Fourth American, from the last Edinburgh Edition Revised by the American editor. In one large 8vo. vol. of nearly 700 pages, with 364 illustrations: cloth, $3 75.

GROSS (SAMUEL D.), M.D.,

Professor of Surgery in the Jefferson Medical College of Philadelphia.

SYSTEM OF SURGERY: Pathological, Diagnostic, Therapeutic, and Operative. Illustrated by upwards of Fourteen Hundred Engravings. Fifth edition, carefully revised and improved. In two large and beautifully printed imperial octavo volumes of about 2300 pp., strongly bound in leather, with raised bands, $15; half Russia, raised bands, $16.

The continued favor, shown by the exhaustion of successive large editions of this great work, proves that it has successfully supplied a want felt by American practitioners and students. In the present revision no pains have been spared by the author to bring it in every respect fully up to the day. To effect this a large part of the work has been rewritten, and the whole enlarged by nearly one-fourth, notwithstanding which the price has been kept at its former very moderate rate. By the use of a close, though very legible type, an unusually large amount of matter is condensed in its pages, the two volumes containing as much as four or five ordinary octavos. This, combined with the most careful mechanical execution, and its very durable binding, renders it one of the cheapest works accessible to the profession. Every subject properly belonging to the domain of surgery is treated in detail, so that the student who possesses this work may be said to have in it a surgical library.

We have seldom read a work with the practical value of which we have been more impressed. Every chapter is so concisely put together, that the busy practitioner, when in difficulty, can at once find the information he requires. His work is cosmopolitan, the surgery of the world being fully represented in it. The work, in fact, is so historically unprejudiced, and so eminently practical, that it is almost a false compliment to say that we believe it to be destined to occupy a foremost place as a work of reference, while a system of surgery like the present system of surgery is the practice of surgeons. The printing and binding of the work is unexceptionable: indeed, it contrasts, in the latter respect, remarkably with English medical and surgical cloth-bound publications, which are generally so wretchedly stitched as to require re-binding before they are any time in use.—*Dub. Journ. of Med. Sci.*, March, 1874.

Dr. Gross's Surgery, a great work, has become still greater, both in size and merit, in its most recent form. The difference in actual number of pages is not more than 130, but the size of the page having been increased to what we believe is technically termed "elephant," there has been room for considerable additions, which, together with the alterations, are improvements.—*Lond. Lancet*, Nov. 16, 1872.

It combines, as perfectly as possible, the qualities of a text-book and work of reference. We think this last edition of Gross's "Surgery," will confirm his title of "*Primus inter Pares.*" It is learned, scholar-like, methodical, precise, and exhaustive. We scarcely think any living man could write so complete and faultless a treatise, or comprehend more solid, instructive matter in the given number of pages. The labor must have been immense, and the work gives evidence of great powers of mind, and the highest order of intellectual discipline and methodical disposition and arrangement of acquired knowledge and personal experience.—*N.Y. Med. Journ.*, Feb 1873.

As a whole, we regard the work as the representative "System of Surgery" in the English language.—*St. Louis Medical and Surg. Journ.*, Oct. 1872.

The two magnificent volumes before us afford a very complete view of the surgical knowledge of the day. Some years ago we had the pleasure of presenting the first edition of Gross's Surgery to the profession as a work of unrivalled excellence; and now we have the result of years of experience, labor, and study, all condensed upon the great work before us. And to students or practitioners desirous of enriching their library with a treasure of reference, we can simply commend the purchase of these two volumes of immense research.—*Cincinnati Lancet and Observer*, Sept. 1872.

A complete system of surgery—not a mere text-book of operations, but a scientific account of surgical theory and practice in all its departments.—*Brit. and For. Med Chir. Rev.*, Jan. 1873.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DISEASES, INJURIES, and Malformations of the Urinary Bladder, the Prostate Gland, and the Urethra. Third Edition, thoroughly Revised and Condensed, by SAMUEL W. GROSS, M.D., Surgeon to the Philadelphia Hospital. In one handsome octavo volume of 574 pages, with 179 illustrations: cloth, $4·50. (*Just Issued.*)

For reference and general information, the physician or surgeon can find no work that meets their necessities more thoroughly than this, a revised edition of an excellent treatise, and no medical library should be without it. Replete with handsome illustrations and good ideas, it has the unusual advantage of being easily comprehended, by the reasonable and practical manner in which the various subjects are systematized and arranged. We heartily recommend it to the profession as a valuable addition to the important literature of diseases of the urinary organs.—*Atlanta Med. Journ.*, Oct. 1876.

It is with pleasure we now again take up this old work in a decidedly new dress. Indeed, it must be regarded as a new book in very many of its parts. The chapters on "Diseases of the Bladder," "Prostate Body," and "Lithotomy," are splendid specimens of descriptive writing; while the chapter on "Stricture" is one of the most concise and clear that we have ever read.—*New York Med. Journ.*, Nov. 1876.

BY THE SAME AUTHOR

A PRACTICAL TREATISE ON FOREIGN BODIES IN THE AIR-PASSAGES. In 1 vol. 8vo., with illustrations, pp. 468, cloth, $2 75.

DRUITT (ROBERT), M.R.C.S., &c.

THE PRINCIPLES AND PRACTICE OF MODERN SURGERY.

A new and revised American, from the eighth enlarged and improved London edition. Illustrated with four hundred and thirty-two wood engravings. In one very handsome octavo volume, of nearly 700 large and closely printed pages, cloth, $4 00; leather, $5 00.

All that the surgical student or practitioner could desire.—*Dublin Quarterly Journal.*

It is a most admirable book. We do not know when we have examined one with more pleasure.—*Boston Med. and Surg. Journal.*

In Mr. Druitt's book, though containing only some seven hundred pages, both the principles and the practice of surgery are treated, and so clearly and perspicuously, as to elucidate every important topic. We have examined the book most thoroughly, and can say that this success is well merited. His book, moreover, possesses the inestimable advantages of having the subjects perfectly well arranged and classified and of being written in a style at once clear and succinct.—*Am. Journal of Med. Sciences.*

HAMILTON (FRANK H.) M.D., LL.D.,

Surgeon to the Bellevue Hospital, New York.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS

Sixth edition, thoroughly revised, and much improved. In one very handsome octavo volume of over 900 pages, with 352 illustrations. Cloth, $5.50; leather, $6.50; half Russia, raised bands, $7 00.

The demand which has so speedily exhausted five large editions of this work, shows that the author has succeeded in supplying a want, felt by the profession at large, of an exhaustive treatise on a frequent and troublesome class of accidents. The unanimous voice of the profession abroad, as well as at home, has pronounced it the most complete work to which the surgeon can refer for information respecting the details of the subject. In the preparation of this new edition, the author has added a chapter on General Prognosis: that on Fractures of the Patella has been entirely rewritten, in order that the results of a recent exhaustive study of this subject might be given, and, in fact, the entire matter of the book has undergone most thorough revision. A number of illustrations have been omitted to make place for new ones, and a few have been inserted from the German edition, published at Göttingen in 1877.

So many kind expressions of welcome have been showered upon each successive edition of this valuable treatise, that scarcely anything remains for us to do but to extend the customary cordial greeting. It is the only complete work on the subject of Fractures in the English language. We congratulate the accomplished author on the deserved success of his work, and hope that he may live to have many succeeding editions pass under his skilled supervision.—*Phila. Coll. and Clin. Record*, Nov 15, 1880.

Dr Hamilton has devoted great labor to the study of these subjects. His large experience, extended research, and patient investigation have made him one of the highest authorities among living writers in this branch of surgery This work is systematic and practical in its arrargement and presents its subject matter clearly and forcibly to the reader or student.—*Maryland Medical Journal*, Nov. 15, 1880.

The only complete work on its subject in the English tongue, and, indeed, may now be said to be the only work of its kind in any tongue. It would require an exceedingly critical examination to detect in it any particulars in which it might be improved. The work is a monument to American surgery, and will long serve to keep green the memory of its venerable author.—*Michigan Med. News*, Nov. 10, 188 .

Universal verdict has pronounced it, humanly speaking, a perfect treatise upon this subject. As it is the only complet and illustrated work in any language treating of fractures and dislocations, it is safe to affirm that every wide-awake surgeon and general practitioner will regard it as indispensable to the safe and pleasant conduct of their professional work —*Detroit Lancet*, Nov. 18, 1880.

The book is known to be the only complete treatise in the English language, or in any language, and needs no recommendation. If there should still be a surgeon who does not have the book in his library, we advise him to get it immediately.—*Buffalo Med. and Surg. Journ.*, Dec. 1880

This is the sixth edition of the only work extant devoted exclusively to fractures and dislocations. That no ambitious surgeon has aspired to enter this field as a rival to Prof. Hamilton is ample testimony to the thoroughness and completeness with which he has done his work.—*Ohio Med. Recorder*, Dec. 1880.

ASHHURST (JOHN, Jr.), M.D.,

Prof of Clinical Surgery, Univ of Pa., Surgeon to the Episcopal Hospital, Philadelphia.

THE PRINCIPLES AND PRACTICE OF SURGERY.

Second edition, enlarged and revised. In one very large and handsome octavo volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7.50 (*Just Ready.*)

Conscientiousness and thoroughness are two very marked traits of character in the author of this book. Out of these traits largely has grown the success of his mental fruit in the past, and the present offer seems in no wise an exception to what has gone before. The general arrangement of the volume is the same as in the first edition, but every part has been carefully revised, and much new matter added.—*Phila. Med. Times*, Feb. 1, 1879.

We have previously spoken of Dr. Ashhurst's work in terms of praise. We wish to reiterate those terms here, and to add that no more satisfactory representation of modern surgery has yet fallen from the press. In point of judicial fairness, of power of condensation, of accuracy and conciseness of expression and thoroughly good English, Prof. Ashhurst has no superior among the surgical writers in America.—*Am. Practitioner*, Jan. 1879.

The attempt to embrace in a volume of 1000 pages the whole field of surgery, general and special, would be a hopeless task unless through the most tireless industry in collating and arranging, and the wisest judgment in condensing and excluding. These facilities have been abundantly employed by the author, and he has given us a most excellent treatise, brought up by the revision for the second edition to the latest date. Of course this book is not designed for specialists, but as a course of general surgical knowledge and for general practitioners, and as a text-book for students it is not surpassed by any that has yet appeared, whether of home or foreign authorship.—*N. Carolina Med. Journal*, Jan. 1879.

Ashhurst's Surgery is too well known in this country to require special commendation from us. This, its second edition, enlarged and thoroughly revised, brings it nearer our idea of a model text-book than any recently published treatise. Though numerous additions have been made, the size of the work is not materially increased The main trouble of text-books of modern times is that they are too cumbersome. The student needs a book which will furnish him the most information in the shortest time. In every respect this work of Ashhurst is the model text-book—full, comprehensive and compact.—*Nashville Jour. of Med. and Surg.*, Jan. '79.

The favorable reception of the first edition is a guarantee of the popularity of this edition, which is fresh from the editor's hands with many enlargements and improvements. The author of this work is deservedly popular as an editor and writer, and his contributions to the literature of surgery have gained for him wide reputation. The volume now offered the profession will add new laurels to those already won by previous contributions. We can only add that the work is well arranged, filled with practical matter, and contains in brief and clear language all that is necessary to be learned by the student of surgery whilst in attendance upon lectures, or the general practitioner in his daily routine practice.—*Md. Med. Journal*, Jan. 1879.

The fact that this work has reached a second edition so very soon after the publication of the first one, speaks more highly of its merits than anything we might say in the way of commendation. It seems to have immediately gained the favor of students and physicians.—*Cincin. Med. News*, Jan. '79.

BRYANT (*THOMAS*), *F.R.C.S.*,

Surgeon to Guy's Hospital.

THE PRACTICE OF SURGERY. Third American, from the Second and Revised English Edition. Thoroughly revised and much improved, by John B. Roberts, M.D. In one large and very handsome imperial octavo volume of over 1000 pages, with 672 illustrations. Cloth, $6 50; leather, $7 50; very handsome half Russia, raised bands, $8 00. (*Just Ready.*)

The marked success of this work on both sides of the Atlantic shows that the author has succeeded in the effort to give the student and practitioner a sound and trustworthy guide in the practice of surgery.

In preparing a new edition, it has seemed best, in order to adapt the work more thoroughly to the needs of the native student, that it should receive the benefits of a revision by an American editor, who should not only incorporate the most recent discoveries, but also the modes of procedure, which must necessarily vary with the practices of different countries.

The work is now confidently presented as worthy a continuance of the very distinguished success which has marked the reception of the previous editions.

ERICHSEN (*JOHN E.*),

Professor of Surgery in University College, London, &c.

THE SCIENCE AND ART OF SURGERY; being a Treatise on Surgical Injuries, Diseases, and Operations. Carefully revised by the author from the Seventh and enlarged English Edition. Illustrated by eight hundred and sixty two engravings on wood. In two large and beautiful octavo volumes of nearly 2000 pages: cloth, $8 50; leather, $10 50; half Russia, $11 50. (*Now Ready.*)

The seventh edition is before the world as the last word of surgical science. There may be monographs which excel it upon certain points, but as a conspectus upon surgical principles and practice it is unrivalled. It will well reward practitioners to read it, for it has been a peculiar province of Mr. Erichsen to demonstrate the absolute interdependence of medical and surgical science We need scarcely add, in conclusion, that we heartily commend the work to students that they may be grounded in a sound faith, and to practitioners as an invaluable guide at the bedside.—*Am. Practitioner*, April, 1878.

It is no idle compliment to say that this is the best edition Mr. Erichsen has ever produced of his well-known book. Besides inheriting the virtues of it's predecessors, it possesses excellences quite its own. Having stated that Mr. Erichsen has incorporated into this edition every recent improvement in the science and art of surgery, it would be a supererogation to give a detailed criticism. In short, we unhesitatingly aver that we know of no other single work where the student and practitioner can gain at once so clear an insight into the principles of surgery, and so complete a knowledge of the exigencies of surgical practice.—*London Lancet*, Feb. 14, 1878

For the past twenty years Erichsen's Surgery has maintained its place as the leading text-book, not only in this country, but in Great Britain. That it is able to hold its ground, is abundantly proven by the thoroughness with which the present edition has been revised, and by the large amount of valuable material that has been added. Aside from this, one hundred and fifty new illustrations have been inserted, including quite a number of microscopical appearances of pathological processes. So marked is this change for the better, that the work almost appears as an entirely new one.—*Med. Record*, Feb. 23, 1878.

Of the many treatises on Surgery which it has been our task to study, or our pleasure to read, there is none which in all points has satisfied us so well as the classic treatise of Erichsen. His polished, clear style, his freedom from prejudice and hobbies, his unsurpassed grasp of his subject, and vast clinical experience, qualify him admirably to write a model text-book. When we wish, at the least cost of time, to learn the most of a topic in surgery, we turn, by preference, to his work. It is a pleasure, therefore, to see that the appreciation of it is general, and has led to the appearance of another edition.—*Med. and Surg. Reporter*, Feb. 2, 1878.

Notwithstanding the increase in size, we observe that much old matter has been omitted. The entire work has been thoroughly written up, and not merely amended by a few extra chapters A great improvement has been made in the illustrations. One hundred and fifty new ones have been added, and many of the old ones have been redrawn. The author highly appreciates the favor with which his work has been received by American surgeons, and has endeavored to render his latest edition more than ever worthy of their approval. That he has succeeded admirably, must, we think, be the general opinion. We heartily recommend the book to both student and practitioner.—*N. Y. Med. Journal*, Feb. 1878.

HOLMES (*TIMOTHY*), *M.D.*,

Surgeon to St. George's Hospital, London.

SURGERY, ITS PRINCIPLES AND PRACTICE. In one handsome octavo volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; leather, $7; half Russia, $7 50. (*Just Issued.*)

This is a work which has been looked for on both sides of the Atlantic with much interest. Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and perhaps the most brilliant writer upon surgical subjects in England. It is a book for students—and an admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its proper limits has not impaired its force and distinctness.—*N. Y. Med. Record*, April 14, 1876.

It will be found a most excellent epitome of surgery by the general practitioner who has not the time to give attention to more minute and extended works and to the medical student. In fact, we know of no one we can more cordially recommend. The author has succeeded well in giving a plain and practical account of each surgical injury and disease, and of the treatment which is most commonly advisable. It will no doubt become a popular work in the profession, and especially as a text-book.—*Cincinnati Med. News*, April, 1876.

ASHTON ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS: with remarks on Habitual Constipation. Second American, from the fourth and enlarged London Edition. With illustrations. In one 8vo. vol. of 287 pages, cloth, $3 25.

SARGENT ON BANDAGING AND OTHER OPERATIONS OF MINOR SURGERY. New edition, with an additional chapter on Military Surgery. One 12mo. vol. of 333 pages with 184 wood-cuts Cloth, $1 75.

WELLS (J. SOELBERG),

Professor of Ophthalmology in King's College Hospital, &c.

A TREATISE ON DISEASES OF THE EYE. Third American, from the Third London Edition. Thoroughly revised, with copious additions, by Chas. S. Bull, M.D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with about 250 engravings on wood, and six colored plates. Together with selections from the Test-types of Jaeger and Snellen. In one large and very handsome octavo volume of 900 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6.50. (*Just Ready.*)

The long-continued illness of the author, with its fatal termination, has kept this work for some time out of print, and has deprived it of the advantage of the revision which he sought to give it during the last years of his life. This edition has therefore been placed under the editorial supervision of Dr. Bull, who has labored earnestly to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision. To accomplish this, considerable additions have been required, and the work is now presented in the confidence that it will fully deserve a continuance of the very marked favor with which it has hitherto been greeted as a complete, but concise, exposition of the principles and facts of its important department of medical science.

The additions made in the previous American editions by Dr. Hays have been retained, including the very full series of illustrations and the test-types of Jaeger and Snellen.

This new edition of Dr. Wells's great work on the eye will be welcomed by the profession at large as well as by the oculist. It contains much new matter relating to treatment and pathology, and is brought thoroughly up with the present status of ophthalmology. Its chapter on refraction and accommodation—a subject much discussed of late years, and of great importance—is exceedingly complete.—*Louisville Med. News*, Nov. 13, 1880.

The merits of Wells's treatise on diseases of the eye have been so universally acknowledged, and are so familiar to all who profess to have given any attention to ophthalmic surgery, that any discussion of them at this late day will be a work of supererogation. Very little that is practically useful in recent ophthalmic literature has escaped the editor, and the third American edition is well up to the times. As a text-book on ophthalmic surgery for the English-speaking practitioner, it is without a rival.—*Am. Journ. of Med. Sci.*, Jan. 1881.

The work has justly held a high place in English ophthalmic literature, and at the time of its first appearance was the best treatise of its kind in the language. In the second edition, the author showed industrious research in adding new material from every quarter, and his spirit was eminently candid. A work thus built up by honest effort should not be suffered to die, and we are pleased to receive this third edition from the hands of Dr. Bull. His labor has been arduous, as the very great number of additions bracketed with his initial testify. Under the editorship which the third edition has enjoyed, the work is sure to sustain its good reputation, and to maintain its usefulness.—*N. Y. Med. Journ.*, Jan. 1881.

There is really no work which approaches it in adaptation to the wants of the general practitioner, while the most advanced specialist cannot rise from a perusal of its ample pages without having added to his knowledge. The American editor, Dr. Bull, won his spurs in ophthalmology some time back. His additions to the work of the lamented Wells are many, judicious, and timely, and in just so much have added to its value.—*Am. Practitioner*, Jan. 1881.

NETTLESHIP (EDWARD), F.R.C.S.,

Ophthalmic Surg. and Lect. on Ophth. Surg. at St. Thomas' Hospital, London.

MANUAL OF OPHTHALMIC MEDICINE. In one royal 12mo. volume of over 350 pages, with 89 illustrations. Cloth, $2. (*Just Ready.*)

The author is to be congratulated upon the very successful manner in which he has accomplished his task; he has succeeded in being concise without sacrificing clearness, and, including the whole ground covered by more voluminous text-books, has given an excellent *résumé* of all the practical information they contain. We do not hesitate to pronounce Mr Nettleship's book the best manual on ophthalmic surgery for the use of students and "busy practitioners" with which we are acquainted.—*Am. Jour. Med. Science*, April, 1880.

CARTER (R. BRUDENELL), F.R.C.S.,

Ophthalmic Surgeon to St. George's Hospital, etc.

A PRACTICAL TREATISE ON DISEASES OF THE EYE. Edited, with test-types and Additions, by JOHN GREEN, M.D. (of St. Louis, Mo.). In one handsome octavo volume of about 500 pages, and 124 illustrations. Cloth, $3 75. (*Just Issued.*)

It is with great pleasure that we can endorse the work as a most valuable contribution to practical ophthalmology. Mr. Carter never deviates from the end he has in view, and presents the subject in a clear and concise manner, easy of comprehension, and hence the more valuable. We would especially commend, however, as worthy of high praise, the manner in which the therapeutics of disease of the eye is elaborated, for here the author is particularly clear and practical, where other writers are unfortunately too often deficient. The final chapter is devoted to a discussion of the uses and selection of spectacles, and is admirably compact, plain, and useful, especially the paragraphs on the treatment of presbyopia and myopia. In conclusion, our thanks are due the author for many useful hints in the great subject of ophthalmic surgery and therapeutics, a field where of late years we glean but a few grains of sound wheat from a mass of chaff.—*New York Medical Record*, Oct. 23, 1875.

BROWNE (EDGAR A.),

Surgeon to the Liverpool Eye and Ear Infirmary, and to the Dispensary for Skin Diseases.

HOW TO USE THE OPHTHALMOSCOPE. Being Elementary Instructions in Ophthalmoscopy, arranged for the Use of Students. With thirty-five illustrations. In one small volume royal 12mo. of 120 pages: cloth, $1. (*Now Ready.*)

LAURENCE'S HANDY-BOOK OF OPHTHALMIC SURGERY, for the use of Practitioners. Second edition, revised and enlarged. With numerous illustrations. In one very handsome octavo volume, cloth, $2 75.

LAWSON'S INJURIES TO THE EYE, ORBIT, AND EYELIDS: their Immediate and Remote Effects. With about one hundred illustrations. In one very handsome octavo volume, cloth, $3 50.

BURNETT (CHARLES H.), M.A., M.D.,

Aural Surg'n to the Presb. Hosp., Surgeon-in-charge of the Instr. for Dis. of the Ear, Phila.

THE EAR, ITS ANATOMY, PHYSIOLOGY, AND DISEASES.

A Practical Treatise for the Use of Medical Students and Practitioners. In one handsome octavo volume of 615 pages, with eighty-seven illustrations: cloth, $4 50; leather, $5 50; half Russia, $6 00. (*Now Ready.*)

Foremost among the numerous recent contributions to aural literature will be ranked this work of Dr. Burnett. It is impossible to do justice to this volume of over 600 pages in a necessarily brief notice. It must suffice to add that the book is profusely and accurately illustrated, the references are conscientiously acknowledged, while the result has been to produce a treatise which will henceforth rank with the classic writings of Wilde and Von Tröltsch.—*The Lond. Practitioner*, May, 1879

On account of the great advances which have been made of late years in otology, and of the increased interest manifested in it, the medical profession will welcome this new work, which presents clearly and concisely its present aspect, whilst clearly indicating the direction in which further researches can be most profitably carried on. Dr. Burnett from his own matured experience, and availing himself of the observations and discoveries of others, has produced a work which, as a text-book, stands *facile princeps* in our language. We had marked several passages as well worthy of quotation and the attention of the general practitioner, but their number and the space at our command forbid. Perhaps it is better, as the book ought to be in the hands of every medical student, and its study will well repay the busy practitioner in the pleasure he will derive from the agreeable style in which many otherwise dry and mostly unknown subjects are treated. To the specialist the work is of the highest value, and his sense of gratitude to Dr. Burnett will, we hope, be proportionate to the amount of benefit he can obtain from the careful study of the book, and a constant reference to its trustworthy pages.—*Edinburgh Med. Jour.*, Aug. 1878.

TAYLOR (ALFRED S.), M.D.,

Lecturer on Med. Jurisp. and Chemistry in Guy's Hospital.

A MANUAL OF MEDICAL JURISPRUDENCE. Eighth American edition.

Thoroughly revised and rewritten. Edited by JOHN J. REESE, M.D., Prof. of Med. Jurisp. and Toxicology in the Univ. of Penn. In one large octavo volume of 933 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

The American editions of this standard manual have for a long time laid claim to the attention of the profession in this country; and that the profession has recognized this claim with favor is proven by the call for frequent new editions of the work. This one, the eighth, comes before us as embodying the latest thoughts and emendations of Dr. Taylor, upon the subject to which he devoted his life, with an assiduity and success which made him *facile princeps* among English writers on medical jurisprudence. Both the author and the book have made a mark too deep to be affected by criticism, whether it be censure or praise. In this case, however, we should only have to seek for laudatory terms.—*Am. Journ. of Med Sci.*, Jan. 1881.

It is not very often that a medical book reaches its tenth edition, or that the last earthly labor is performed by the author in retouching the work that first came from his hand thirty-five years before. All this, however, has happened in the case of Dr. Taylor and his classical treatise. The pen dropped from the grasp only when the shadows of old age were rapidly deepening into the darkness of death. Under the circumstances, all the journalist has to do is to announce, not criticize, the completed task. The value of the gem is too well known to require more than the telling that the master-hand has rebrightened its facets and polished its angles before leaving it as his legacy to his brethren in the profession.—*Phila Med. Times*, Dec. 4, 1880.

It will suffice to remark that this new edition shows the signs of judicious revision. A great number of illustrative medico-legal cases which have occurred since the last edition was published are cited in their proper connection, and add much to the interest and value of the work; they comprise the bulk of the additions to the text. As an indication of the freshness of the work, we notice numerous references to medico-legal experience that has transpired during the year just ended; among these is a comment by the American editor upon that midsummer madness, the Tanner fasting exploit of last August. In these features and in others there is ample evidence that this admirable book will maintain its high place as a standard authority concerning the matters of which it treats.—*Boston Med. and Surg. Journal*, Jan. 13, 1881.

BY THE SAME AUTHOR.

THE PRINCIPLES AND PRACTICE OF MEDICAL JURISPRUDENCE.

Second Edition, Revised, with numerous Illustrations. In two large octavo volumes, cloth, $10 00; leather, $12 00

This great work is now recognised in England as the fullest and most authoritative treatise on every department of its important subject. In laying it, in its improved form, before the American profession, the publishers trust that it will assume the same position in this country.

BY THE SAME AUTHOR.

POISONS IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE.

Third American, from the Third and Revised English Edition. In one large octavo volume of 850 pages; cloth, $5 50; leather, $6 50. (*Just Issued.*)

The present is based upon the two previous editions; "but the complete revision rendered necessary by time has converted it into a new work." This statement from the preface contains all that it is desired to know in reference to the new edition. The works of this author are already in the library of every physician who is liable to be called upon for medico-legal testimony (and what one is not?), so that all that is required to be known about the present book is that the author has kept it abreast with the times. What makes it now, as always, especially valuable to the practitioner is its conciseness and practical character, only those poisonous substances being described which give rise to legal investigations.—*The Clinic*, Nov. 6, 1875.

Dr. Taylor has brought to bear on the compilation of this volume, stores of learning, experience, and practical acquaintance with his subject, probably far beyond what any other living authority on toxicology could have amassed or utilized. He has fully sustained his reputation by the consummate skill and legal acumen he has displayed in the arrangement of the subject-matter, and the result is a work on Poisons which will be indispensable to every student or practitioner in law and medicine.—*The Dublin Journ. of Med Sc.*, Oct. 1875.

ROBERTS (*WILLIAM*), *M.D.*,
Lecturer on Medicine in the Manchester School of Medicine, etc.

A PRACTICAL TREATISE ON URINARY AND RENAL DISEASES, including Urinary Deposits. Illustrated by numerous cases and engravings. Third American, from the Third Revised and Enlarged London Edition. In one large and handsome octavo volume of over 600 pages. Cloth, $4. (*Just Ready.*)

THOMPSON (*SIR HENRY*),
Surgeon and Professor of Clinical Surgery to University College Hospital.

LECTURES ON DISEASES OF THE URINARY ORGANS. With illustrations on wood. Second American from the Third English Edition. In one neat octavo volume. Cloth, $2 25. (*Just Issued.*)

BY THE SAME AUTHOR.

ON THE PATHOLOGY AND TREATMENT OF STRICTURE OF THE URETHRA AND URINARY FISTULÆ. With plates and wood-cuts. From the third and revised English edition. In one very handsome octavo volume, cloth, $3 50. (*Lately Published.*)

TUKE (*DANIEL HACK*), *M.D.*,
Joint author of The Manual of Psychological Medicine, &c.

ILLUSTRATIONS OF THE INFLUENCE OF THE MIND UPON THE BODY IN HEALTH AND DISEASE. Designed to illustrate the Action of the Imagination. In one handsome octavo volume of 416 pages, cloth, $3 25. (*Lately Issued.*)

BLANDFORD (*G. FIELDING*), *M.D., F.R.C.P.*,
Lecturer on Psychological Medicine at the School of St. George's Hospital, &c.

INSANITY AND ITS TREATMENT: Lectures on the Treatment, Medical and Legal, of Insane Patients. With a Summary of the Laws in force in the United States on the Confinement of the Insane. By ISAAC RAY, M. D. In one very handsome octavo volume of 471 pages; cloth, $3 25.

It satisfies a want which must have been sorely felt by the busy general practitioners of this country. It takes the form of a manual of clinical description of the various forms of insanity, with a description of the mode of examining persons suspected of insanity. We call particular attention to this feature of the book, as giving it a unique value to the general practitioner. If we pass from theoretical considerations to descriptions of the varieties of insanity as actually seen in practice and the appropriate treatment for them, we find in Dr. Blandford's work a considerable advance over previous writings on the subject. His pictures of the various forms of mental disease are so clear and good that no reader can fail to be struck with their superiority to those given in ordinary manuals in the English language or (so far as our own reading extends) in any other.—*London Practitioner*, Feb. 1871.

LEA (*HENRY C.*).

SUPERSTITION AND FORCE: ESSAYS ON THE WAGER OF LAW, THE WAGER OF BATTLE, THE ORDEAL, AND TORTURE. Third Revised and Enlarged Edition. In one handsome royal 12mo. volume of 552 pages. Cloth, $2 50. (*Just Ready.*)

This valuable work is in reality a history of civilization as interpreted by the progress of jurisprudence. . . . In "Superstition and Force" we have a philosophic survey of the long period intervening between primitive barbarity and civilized enlightenment. There is not a chapter in the work that should not be most carefully studied, and however well versed the reader may be in the science of jurisprudence, he will find much in Mr. Lea's volume of which he was previously ignorant. The book is a valuable addition to the literature of social science.—*Westminster Review*, Jan. 1880.

The appearance of a new edition of Mr. Henry C. Lea's "Superstition and Force" is a sign that our highest scholarship is not without honor in its native country. Mr. Lea has met every fresh demand for his work with a careful revision of it, and the present edition is not only fuller and, if possible, more accurate than either of the preceding, but, from the thorough elaboration is more like a harmonious concert and less like a batch of studies.—*The Nation*, Aug. 1, 1878.

Many will be tempted to say that this, like the "Decline and Fall," is one of the uncriticizable books. Its facts are innumerable, its deductions simple and inevitable, and its *chevaux-de-frise* of references bristling and dense enough to make the keenest, stoutest, and best equipped assailant think twice before advancing. Nor is there anything controversial in it to provoke assault. The author is no polemic. Though he obviously feels and thinks strongly, he succeeds in attaining impartiality. Whether looked on as a picture or a mirror, a work such as this has a lasting value.—*Lippincott's Magazine*, Oct. 1878.

BY THE SAME AUTHOR.

STUDIES IN CHURCH HISTORY. THE RISE OF THE TEMPORAL POWER—BENEFIT OF CLERGY—EXCOMMUNICATION. In one large royal 12mo. volume of 516 pp.; cloth, $2 75. (*Lately Published.*)

The story was never told more calmly or with greater learning or wiser thought. We doubt, indeed, if any other study of this field can be compared with this for clearness, accuracy, and power.—*Chicago Examiner*, Dec. 1870.

Mr. Lea's latest work, "Studies in Church History," fully sustains the promise of the first. It deals with three subjects—the Temporal Power, Benefit of Clergy, and Excommunication, the record of which has a peculiar importance for the English student, and is a chapter on Ancient Law likely to be regarded as final. We can hardly pass from our mention of such works as these—with which that on "Sacerdotal Celibacy" should be included—without noting the literary phenomenon that the head of one of the first American houses is also the writer of some of its most original books.—*London Athenæum*, Jan. 7, 1871.

NEW MEDICAL BOOKS.

THOMAS ON WOMEN—New and Revised Edition—Just Ready.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. By T. GAILLARD THOMAS, M.D., Prof. of Obstetrics, etc., in the College of Physicians and Surgeons, New York. Fifth edition, thoroughly revised and rewritten. In one large and handsome octavo volume of 806 pages, with 266 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50.

An examination of the work will satisfy that it is one of great merit. It is not a mere compilation from other works, but it is the fruit of the ripe thought, sound judgment, and critical observations of a learned, scientific man. It is a treasury of knowledge of the department of medicine to which it is devoted. In its present revised state it certainly holds a foremost position as a gynæcological work, and will continue to be regarded as a standard authority.—*Cincinnati Med. News*, Dec. 1880.

This work needs no introduction to any of the civilized nations of the world. The edition before us adds to the strength of former volumes. With the wisdom of a master teacher he here gives the results that, in his judgment, are most trustworthy at the present time. In its own place it has no rival, because the author is the best teacher on this subject to the masses of the profession. As hitherto this work will be the text-book on diseases of women. We only wish that in other branches of medicine as capable teachers could be found to write our text-books.—*Detroit Lancet*, Jan. 1881.

BRYANT'S SURGERY—New Edition—Just Ready.

THE PRACTICE OF SURGERY. By THOMAS BRYANT, F.R.C.S., Surgeon to Guy's Hospital. Third American, from the Second and revised English edition. Thoroughly revised and much improved, by JOHN B. ROBERTS, M.D. In one large and very handsome imperial octavo volume of over 1050 pages, with 767 illustrations. Cloth, $6 50; leather, $7 50; very handsome half Russia, raised bands, $8.

The marked success of this work on both sides of the Atlantic shows that the author has succeeded in the effort to give the student and practitioner a sound and trustworthy guide in the practice of surgery.

In preparing a new edition, it has seemed best, in order to adapt the work more thoroughly to the needs of the native student, that it should receive the benefits of a revision by an American editor, who should not only incorporate the most recent discoveries, but also the modes of procedure, which must necessarily vary with the practices of different countries.

The work is now confidently presented as worthy a continuance of the very distinguished success which has marked the reception of the previous editions.

TAYLOR'S MEDICAL JURISPRUDENCE—New Edition—Just Ready.

A MANUAL OF MEDICAL JURISPRUDENCE. By ALFRED S. TAYLOR, M.D., late Lecturer on Medical Jurisprudence and Chemistry in Guy's Hospital, London. Eighth American edition. Edited by JOHN J. REESE, M.D., Professor of Medical Jurisprudence and Toxicology in the Univ. of Penna. In one large and very handsome 8vo. vol. of 933 pages, with illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50.

The American editions of this standard manual have for a long time laid claim to the attention of the profession in this country; and that the profession has recognized this claim with favor is proven by the call for frequent new editions of the work. This one, the eighth, comes before us as embodying the latest thoughts and emendations of Dr. Taylor, upon the subject to which he devoted his life, with an assiduity and success which made him *facile princeps* among English writers on medical jurisprudence. Both the author and the book have made a mark too deep to be affected by criticism, whether it be censure or praise. In this case, however, we should only have to seek for laudatory terms.—*Am. Journ. of Med. Sciences*, Jan. 1881.

It is not very often that a medical book reaches its tenth edition, or that the last earthly labor is performed by the author in retouching the work that first came from his hand thirty-five years before. All this, however, has happened in the case of Dr. Taylor and his classical treatise. The pen dropped from the grasp only when the shadows of old age were rapidly deepening into the darkness of death. Under the circumstances, all the journalist has to do is to announce, not criticize, the completed task. The value of the gem is too well known to require more than the telling that the master-hand has rebrightened its facets and polished its angles before leaving it as his legacy to his brethren in the profession.—*Phila. Med. Times*, Dec. 4, 1880.

CLOWES'S CHEMISTRY—New Edition—Just Ready.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS. Specially adapted for use in the Laboratories of Schools and Colleges, and by Beginners. By FRANK CLOWES, D.Sc. London. Senior Science Master at the High School, Newcastle-under-Lyme, etc. Second American, from the Third and Revised English Edition. In one very handsome 12mo. volume of 372 pages, with 47 illustrations. Cloth, $2 50.

HAMILTON ON FRACTURES—New Edition—Just Ready.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS. By FRANK H. HAMILTON, M.D., LL.D., Surgeon to Bellevue Hospital, N. Y., etc. Sixth edition, thoroughly revised and much improved. In one very handsome octavo volume of 905 pages, with 352 illustrations. Cloth, $5 50; leather, $6 50; half Russia, raised bands, $7.

WELLS ON THE EYE—New Edition—Just Ready.

A TREATISE ON DISEASES OF THE EYE. By J. SOELBERG WELLS, late Professor of Ophthalmology in King's College Hospital, London. Third American, from the Third English edition. Thoroughly revised, with copious notes and additions, by CHARLES S. BULL, M.D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with over 250 engravings on wood and six colored plates, together with selections from the test-types of Jaeger and Snellen. In one large and very handsome octavo volume of 900 pages. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50.

HENRY C. LEA'S SON & CO.—Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing its sixty-first year, the publishers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "THE MEDICAL NEWS AND ABSTRACT," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of FIVE DOLLARS *per annum*.

The "NEWS AND ABSTRACT" consists of sixty-four pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, contributed by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "MONTHLY ABSTRACT," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "NEWS AND ABSTRACT" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and
The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum),
} Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance,
} Five Dollars.
The MEDICAL NEWS AND ABSTRACT, invariably in advance, Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

PHILADELPHIA:
HENRY C. LEA'S SON & CO
1881.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

Entered according to the Act of Congress, in the year 1881, by HENRY C. LEA'S SON & CO., in the Office of the Librarian of Congress. All rights reserved.

NEW MEDICAL WORKS.

BARTHOLOW ON ELECTRICITY—In Press.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATIONS TO MEDICINE. By ROBERTS BARTHOLOW, A.M., M.D., LL.D., Professor of Materia Medica and General Therapeutics in the Jefferson Medical College of Philadelphia. In one very handsome 12mo. volume of about 300 pages, with numerous illustrations.

The constantly increasing therapeutic use of electricity, and the absence of a concise guide suited to the wants of the general practitioner, have induced the author to prepare the present volume. His object has been to present the most advanced state of existing knowledge in a form divested of unnecessary technicalities, keeping constantly in view the practical needs of the student and physician.

Dr. Bartholow's power of lucid exposition is well known, and is particularly desirable in a subject such as this, treated from the standpoint of the general practitioner, and not of the specialist. The exceedingly thorough manner in which the subject has been treated may be gathered from the following

CONDENSED SUMMARY OF CONTENTS.

ELECTRO-PHYSICS.—CHAP. I. Magnetism. II. Static Electricity. III. Dynamical Electricity. IV. Forms of Galvanic Combinations. V. Electro-Magnetism. VI. Magneto-Electricity. VII. Electro-Magnetic and Magneto-Electric Batteries for Medical Use. VIII. Care of Batteries, Galvanic and Faradic; Manipulation.

ELECTRO-PHYSIOLOGY.—CHAP. I. Animal Electricity. II. Action of Galvanic Current on Motor, Sensory and Mixed Nerves. III. Action of Induced or Faradic Currents on Motor, Sensory and Mixed Nerves. IV. Action of Galvanic and Faradic Electricity on the Sympathetic and Vaso-Motor Systems. V. Action of Galvanic and Faradic Electricity on Muscle, Striated and Non-Striated. VI. Action of Galvanic and Faradic Currents on the Cerebro-Spinal Axis. VII. Action of Galvanic and Faradic Currents on the Pneumogastric Nerve and Heart. VIII. Action of Electricity on the Special Senses.

ELECTRO DIAGNOSIS.—CHAP. I. Electro-Contractility. II. Electro-Sensibility.

ELECTRO-THERAPEUTICS.—CHAP. I. Electricity in Cerebral Affections. II. Electricity in Spasm and Cramp. III. Electricity in the Paralyses, Spinal, Peripheral, Hysterical, Diphtheritic and Lead. IV. Electricity in the Treatment of Pain. V. Electricity in Anæsthesia and Analgesia. VI. Electricity in the Vaso Motor and Trophic Neuroses. VII. Electricity in Constitutional Diseases. VIII. Electricity in Local, other than Nervous, Diseases.

MITCHELL ON NERVOUS DISEASES OF WOMEN—In Press.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, ESPECIALLY IN WOMEN. By S. WEIR MITCHELL, M.D., Physician to the Orthopædic Hospital and Infirmary for Diseases of the Nervous System. In one very handsome 12mo. volume of about 250 pages, with five lithographic plates.

The life-long devotion of the author to the subjects discussed in this volume has rendered it eminently desirable that the results of his labors should be embodied for the benefit of those who may experience the difficulties connected with the treatment of this class of disease. Many of these lectures are fresh studies of hysterical affections; others treat of the modifications his views have undergone in regard to certain forms of treatment, while, throughout the whole work, he has been careful to keep in view the practical lessons of his cases. The scope of the volume may be gathered from the following

CONDENSED SUMMARY OF CONTENTS.

LECTURE I.—The Paralyses of Hysteria. II. Hysterical Motor Ataxia—Hysterical Paresis. III. Mimicry of Disease. IV. Mimicry of Disease. V. Unusual Forms of Spasmodic Affections in Women. VI. Tremor—Chronic Spasms. VII. Chorea of Childhood. VIII. Habit Chorea. IX. Disorders of Sleep in Nervous or Hysterical Persons. X. Vaso-Motor and Respiratory Disorders in the Nervous or Hysterical. XI. Hysterical Aphonia. XII. Gastro-Intestinal Disorders of Hysteria. XIII. The Treatment of Nervous Exhaustion and Hysteria by Seclusion, Rest, Massage, Electricity and Full Feeding.

ALLEN'S ANATOMY—Shortly.

A SYSTEM OF HUMAN ANATOMY: including its Medical and Surgical Relations. For the use of Practitioners and Students of Medicine. By HARRISON ALLEN, M.D., Prof. of Comparative Anatomy and Physiology in the Univ. of Pa. With an introductory chapter on Histology, by E. O. SHAKESPEARE, M.D., Ophthalmologist to the Philadelphia Hospital. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text.

RICHARDSON'S PREVENTIVE MEDICINE—Shortly.

PREVENTIVE MEDICINE. By BENJAMIN RICHARDSON, M.D., F.R.S., M.A., LL.D., F.S.A., Fellow of the Royal College of Physicians, London. In one 8vo. vol. of about 500 pages.

CLOWES' CHEMISTRY—New Edition—Just Ready.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS. By FRANK CLOWES, D.Sc. London, Senior Science Master at the High School, Newcastle-under-Lyme. Specially adapted for use in the Laboratories of Schools and Colleges, and by Beginners. Second American, from the Third and Revised English edition, with about 50 illustrations on wood. In one very handsome royal 12mo. volume of 372 pages. Cloth, $2 50.

Clinical Lectures.

ACUTE TRICHINIASIS, MARKED BY CONTINUOUS FEVER AND SEVERE MUSCULAR SYMPTOMS.

A CLINICAL LECTURE DELIVERED AT THE PENNSYLVANIA HOSPITAL,

BY J. M. DA COSTA, M.D.,

PROFESSOR OF PRACTICE OF MEDICINE IN JEFFERSON MEDICAL COLLEGE, AND PHYSICIAN TO THE PENNSYLVANIA HOSPITAL.

[Reported by Frank Woodbury, M.D.]

GENTLEMEN: The case now before you is a striking one from more than one point of view. It presents a typical illustration of a disease which I have rarely had the opportunity of presenting before the class. It is interesting in its causation and the question of possible prevention. It is instructive in the accuracy of which the diagnosis admits.

In narrating the history of the case I shall tell you particularly of the condition of the patient when he entered the hospital, for it was a little different then from his present state. His name is Richard E.; he is a German, 20 years of age, a machinist by occupation. He stated positively that he had always been in very good health up to the beginning of his present illness. For a week or two before admission into the hospital, which was on the 7th of December, he suffered from cold in going to and returning from his work. But as he had no underclothing and only wore his overcoat on Sundays, it might be naturally supposed that want of proper clothing was the cause of the chilliness. However this may be, he says that about four days before admission, and following the chilliness of which he complained, he had headache and muscular soreness; he was also very restless, the skin was covered with perspiration, his extremities were cold. This discomfort increased rapidly, became attended by fever, loss of appetite, and constipation; on the day before he came here he had a spell of vomiting. There had been no convulsions, no active delirium, and no signs of brain disorder beyond a dull headache, with confusion of ideas. Now it was in this state that he sought admission into the hospital. When I saw him I was much struck with the appearance of his face. It was flushed, and had a bloated look; the fulness was not confined to the eyelids, but was general, diffused, and had changed the expression of the

entire face. His eyes were clear, the pupils rather dilated. He was, when I met him, wandering in an aimless sort of way at the hospital gate. His face gave me the impression that he was a case of typhoid or rather of typhus fever, though it was not so deeply flushed as we find it in this complaint. His joints were not affected; they were not markedly swollen and certainly were not discoloured, nor were they the seat of special heat or pain. He persisted, however, in calling our attention to the general muscular aching, the stiffness, and the tenderness, at least so far as he spoke of anything, for he was very dull in his mind. Though he was stupid, he was at the same time extremely restless; the muscular soreness was so great that he could not rest, and he did not seem to be able to make himself comfortable in any position. His tongue was red and slightly coated; the breath very fetid; the abdomen swollen; the feet were also a little swollen, but there was no pitting upon pressure. The general surface seemed more or less bloated and pale, there was no eruption of any kind. The urine was of the specific gravity of 1026, acid in its reaction, and contained an excess of urea and of urates, but neither albumen nor sugar. He had a temperature of 104° in the axilla; his bowels had been constipated for several days. He was purged with castor oil, he had quinia given to him, and subsequently muriatic acid, and various means were tried to relieve the muscular soreness. The redness of face soon passed off, and it became pallid and looked swollen; but it did not remain so, the puffiness disappeared in a few days. A slight œdema of the lower extremities, shown especially by the pitting on pressure at both ankles, also passed off in a few days.

The tongue, as you see, has remained red; his appetite is better, indeed it is very good; the fetor of the breath has measurably disappeared; he still complains greatly of the muscular pains. All this time he has had a fever temperature; in the first six or seven days after admission it did not pass below 101°, and ranged between this point and 104°.

Abdominal soreness he has not got. There is some tenderness in the muscular wall, especially is this noticed in the chest, and there is soreness too in the muscles of the extremities, though by no means so much as it was some time since. The respirations have never exceeded twenty-six in the minute, have been more generally twenty-two, and regular. The heart sounds are distinct, evidently no valvular lesion exists, but towards the left base can be found a faint anæmic murmur. The respiratory murmur is everywhere well heard. Now, what is the matter with the patient? Is it muscular rheumatism? Dengue, or breakbone fever? Is it typhoid fever? We concluded that it was not a case of muscular rheumatism, not breakbone fever, and not typhoid. The muscular rheumatism view had a good deal in its favour; his exposure to cold and his insufficient clothing, the great muscular soreness, the chills. But I could not account in this view for the continued fever, the stupor, the expressionless bloated face. The view of typhoid or typhus fever had much to commend it; the continuous character of the fever, with only slight remissions in the morning, his nervous symptoms, his flushed, pallid face, all looked like a low fever. The absence of enteric symptoms was against typhoid but not against typhus; but the absence of eruption was strongly against typhus. Dengue, not being a disease of this time of the year, and not belonging to this latitude, I need not discuss; the symptoms, moreover, appeared too grave for it.

If not any of these affections, what was it? It occurred to me that it

was a case of trichiniasis, a disease produced by the introduction into the system of the trichina spiralis in immense numbers, from partaking of ham, sausage, and other forms of infected pork. The view of trichiniasis gained upon me, I may say upon all of us, for these reasons. Trichiniasis gives rise to a fever that is very similar to that of typhoid fever; we have, in this case, you remember, a low form of continued fever. What also arrested my attention was this: the face looked stupid, swollen, flushed, and then pallid; without there being any albumen in the urine, and the swelling passed off in a few days. This also belongs to the history of acute trichiniasis; this swelling particularly is characteristic, and in most cases is even more decided than in this one before you. But, above all was the great muscular soreness which I was unable to account for as a symptom of continued fever. Nor could it be accounted for as a muscular rheumatism; because the sustained temperature was not that of rheumatism as it occurs in the muscular system, nor in rheumatism do we find the entire muscular system involved, but rather the pain and tenderness limited, especially to certain groups of muscles. Therefore, having all this in mind, I diagnosticated trichiniasis. I put the diagnosis to the test, and after some delay, occasioned by attempts to procure instruments for examining muscles—which were found not to work—we etherized the patient, and cut out a small piece of his deltoid muscle. Placing it under the microscope, it was found swarming with living and most active trichinæ.

We have then here a case of trichiniasis; and I have told you by what steps we arrived at the diagnosis, which was finally confirmed by the actual inspection of the muscles. You see that it was chiefly reached by exclusion; although there were, as I shall presently explain to you, one or two features in the case, in themselves of direct significance.

But has this patient had all the features of acute trichiniasis? No; a number were wanting, others indistinct. In acute trichiniasis from the introduction into the stomach of infected pork, we have generally much more marked symptoms of gastro-intestinal irritation than were here presented; the parasites in the stomach and bowels occasion them. He had great fetor of breath, and vomiting on the day before admission; but only on that occasion, and there was no diarrhœa, the intestinal symptoms were absent, loss of appetite in the early stage certainly existed, but he recovered his appetite better and much more quickly than most of the cases do. Again in pointing out to you anomalies of the early stages, let me tell you that he denied being fond of pork, ham, or sausage, said that he rarely ate it, and that there was not a single one of his friends in the boarding house where he lived that had similar symptoms or had complained of any signs of gastro-intestinal irritation. Generally the history of several persons being stricken at the same time and being seized with cramps, with vomiting, with purging, is a strong element in the diagnosis of this perilous affection.

Looking now at the chief symptoms of the case, we are first struck with the character of the *fever*. It was essentially a continuous fever; the highest temperature reached was 104°, and though in the first ten days there were at times quite marked differences between morning and evening, the temperature subsequently became more and more uniform.

Here is the record kept from the day of admission, so slight are the variations between morning and evening that we may take it as illustrating the course of an ordinary continued fever of long duration. With this elevation of temperature he had the accelerated pulse corresponding

to the rise of bodily heat. There was indeed little about the continuous fever that would have arrested our attention as being different from any other fever of the type, except the remarkable absence of cerebral symptoms. Apart from the headache which existed, the fever was marked by the want of hebetude and of hallucinations of every kind, the mind at first dull, became brighter and quite clear, although the fever persisted.

Secondly, what arrested our attention in connection with the febrile state was the unusual *appearance of the face*—the features swollen, the face later pallid, but at first the cheeks and forehead flushed—looking like the face of typhus fever, but not associated with any marked dulness of expression of the eye, nor with that hebetude which is so thoroughly characteristic of the physiognomy of typhus.

Now while we are examining this swelling of the face, which, let me add, was a passing symptom, and which subsided leaving for a time moderately swollen eyelids, I will call your attention to the fact that for three or four days, for even a shorter period therefore than the swelling of the face existed, he had some œdema around the ankles, but without a particle of albuminuria. The slight dropsical symptoms were therefore not among the earliest symptoms, nor were they late symptoms, since they were noticed not long after the patient was admitted to the hospital, and I think existed markedly about the middle of the second week of the disease, and swelling of the face occurred prior to this. The œdema did not pass away in consequence of any profuse sweating, for almost throughout absence of sweating has been a remarkable and unusual feature of the case, unusual because profuse sweats are quite common in trichiniasis.

But after all the most striking symptoms of the case were the *muscular symptoms.* The phenomena were those of a most extended muscular rheumatism. The pains affected the muscles all over the body, and were present whether motion was made or not, although they were very much aggravated by motion; the muscles were also nearly everywhere sore to the touch, and some felt swollen. None were contracted, but some were so much affected that certain muscular movements could not be effected; for instance, our patient could not stoop. The muscles responded to the faradic current;. the sensibility of the skin over them seemed normal. The muscular symptoms are directly due to the migration of the trichinæ into the muscles, and to the irritation and havoc in the fibrillæ, and to the inflammatory changes in the sarcolemma, by which the capsule that stops their mischievous career is finally formed. Many of the trichinæ we found were very large and very vigorous; indeed, muscular trichinæ are generally large and vigorous; and it is said that they may live or reproduce themselves for years in the muscles of their unwilling possessor.

The muscular symptoms are said not to happen before the tenth day of the disease; but unless we are utterly misinformed here as to the duration of the case, they began to be noticed in the first four or five days of the illness. Let me add, that of the many local means that were tried for the relief of the local distress but one seemed to be of any benefit, and that was a liniment containing about one ounce of chloral to four of camphorated oil. Let me also again impress upon you that attending the muscular symptoms was an amount of prostration and low fever, which was entirely unlike what occurs in ordinary rheumatism; and that, on the other hand, the muscular pains were greatly in excess of any which would happen in a continued fever.

January 15th, 1881. Gentlemen, after the lapse of three weeks, I show

you this patient again; and now it is clear that he is approaching convalescence. Indeed, when you look at the good colour of his lips, his improved general nutrition, the fact that he can perform a number of movements well, which previously stiffness and pain prevented him from executing, all demonstrate the correctness of this conclusion. Accepting it, let us discuss what has become of the trichinæ. Under the treatment of moderate doses of quinia and of tincture of iron, under good food, and after the diagnosis of trichiniasis was made, under carbolic acid, under anodyne liniments, and occasional hypodermics of morphia, the symptoms have much ameliorated; some of them have passed entirely away. To what shall we attribute the striking change? I should like to say to the carbolic acid, but I cannot think it would be a truthful inference. I think that he would have recovered without it, because improvement had commenced before he began to use it. I believe his recovery was due to a good constitution, good nursing, and good food, enabling him to withstand the shock of the mishap until time had brought about certain curative processes, which I shall presently explain to you.

You will ask me what is the ordinary course of the disease, and is recovery from trichiniasis the rule? Also, under what plan of treatment does recovery most often take place? Gentlemen, the course of the disease is very uncertain, being influenced by the accident of the intrusion of the disease into internal organs impossible to foresee, but the duration of the disease is generally very protracted, the muscles being affected in their movements for a long time by the multitudes of trichinæ which become deposited in their structure. Until the parasites become encysted or encapsuled in the muscular fibre, more or less irritative fever persists, the patient begins to recover only when the trichinæ become incarcerated. Subsequently these living worms, after a certain lapse of time, thus far undetermined, perish, and their cysts undergo calcareous degeneration, or it may be that calcareous deposits take place in the capsule, and the parasite becomes choked up with the earthy salts. While this is going on the fever gradually declines, and the muscular soreness and stiffness are gradually relieved, but the impairment of muscular power is much more permanent. In the present case, you have observed a continuous fever lasting over four weeks, and you see that it is only in the last week that the temperature has reached the normal. There is a steady decline from the time of admission; but it did not really descend to the norm until four days ago. It is a continuous fever, varying slightly from week to week, and gradually lessening; but for all this it does not reach the healthy standard until the fifth week, going hand in hand with this process of encapsuling; which, however, is far from complete, for in a specimen of muscle just examined we still find some very lively trichinæ. But does recovery always take place? By no means; of course it does not where the nervous system is invaded or prominently implicated, or the respiratory muscles attacked, and their functions crippled, or where long-continued diarrhœa exists. But even in cases such as this, chiefly marked by the muscular symptoms, and presenting these in a striking degree, the patient often dies from the universal presence of trichinæ in the muscular system, and the irritation they cause. Moreover, although this was not here the case, frequently recovery is impeded or altogether prevented by very decided coexisting affection of the gastro-intestinal tract, producing long-continued vomiting and purging. While this renders the diagnosis much easier, it is a bad thing in point of prognosis, because, in these cases of

gastro-enteric irritation, there is not only an element of additional exhaustion thus acting, but they leave behind them dysentery, diarrhœa, and chronic bowel complaints, or affections of the stomach.

Is recovery complete in those muscular cases where, as here, a cure is apparently obtained? Will this man recover entirely? I think yes. The chances are that every trichina will become encapsuled; I see no reason why this should not occur. At the same time, I will not say that a man in whom exist many millions of trichinæ imbedded in his muscles, as I believe is the case in our patient, would ever be as strong as he was without them. But we may tell him that he will recover completely to all intents and purposes, be fully able to earn his livelihood.

The treatment, as you are aware, was conducted mainly—excepting the carbolic acid—upon the general principle of supporting strength and relieving pain; the great object being to keep up the patient's strength until the parasites became encysted and harmless. But you may inquire, Is there nothing specific to cure trichiniasis by killing the trichinæ? I tried carbolic acid in this patient; but, as I told you, I cannot claim that it was very effectual, because recovery had already begun before it was administered; still it was well borne, and I think the patient improved more rapidly under its administration than before. I shall, in other cases, try it again. It does not disturb the stomach, and on account of its destructive action upon low forms of life, it may, if we can get enough into the system, poison the parasite. Let me add that under the field of the microscope the trichinæ we found live less than a minute on addition of a concentrated solution of carbolic acid.

Benzine, given internally, has been highly recommended for the purpose of their destruction; but the German physicians, who have the greatest opportunities for studying trichiniasis, have abandoned the use of benzine; and so with picric acid, urged for a time as a valuable remedy, it has now entirely fallen into disuse; and calomel, oil of turpentine, and electricity have proved very disappointing. The treatment now followed by several distinguished authorities, consists in giving large doses of glycerine, based upon the observation that when the living trichina is placed in glycerine, it quickly shrivels and dies. We have ourselves tested the matter here, and Dr. Jiminez, the resident physician, found, no matter how active the trichinæ under the microscope, that they perish at once when brought in contact with a drop of glycerine. I would advise you to try glycerine early in a case; at all events it will kill most likely the trichinæ in the stomach and intestine, without being injurious to the patient. Whether it will kill those in the blood and in the muscles is a different question, and I doubt much whether any amount of glycerine given by the mouth will accomplish this. But laying aside the administration of glycerine and of carbolic acid, the main treatment is, I regret to say, nothing better than to support the patient's strength until the encapsuling is accomplished.

Let me say, in conclusion, a few words about the way in which we got at the trichinæ. We had, as I told you, to cut down upon the muscle after etherizing our patient. This, you will admit, is not a pleasant method of diagnosis, but we were obliged to do it; for we found that the ordinary Duchenne trocar, and the harpoon made for the purpose would not work. They fill with blood; they do not extract the muscle. Nor was another appliance, sent by an instrument-maker, more successful. It was very large; a kind of a cross between a bullet extractor and an obstetrical forceps. Dr. R. N. Hart, one of the resident surgeons of this hospital, then came to our assistance, and has invented an ingenious instrument for the object of ex-

tracting muscle for microscopical examination, which promises to be very valuable. I here show you the instrument, which we have now used several times with great ease, and which I shall describe to you in Dr. Hart's own words.

The instrument consists of a small trocar and canula, with a supplementary trocar bearing a peculiar-shaped point (see fig.), the object of which is to secure and remove a small portion of animal tissue for examination. After the plain trocar and canula are inserted into the interior of the muscle or tumour, the trocar is withdrawn, leaving the canula in place. The stylet or cutting portion of the instrument, consists of a steel stem, of the same diameter as the first trocar, at the end of which is a contracted portion, and terminates in a cutting screw edge. By a few rotations of this instrument a fragment of tissue can be secured and removed through the canula. If the first attempt is unsuccessful it can be re-introduced, and any number of successive specimens removed without the necessity of a second puncture, as would be required in using Duchenne's instrument.

Feb. 15. I add a short note concerning the further progress of the case. The man walks about the hospital yard, and looks like a well man. His colour is excellent; he is plump. The pupil has lost all dilatation, and he sees clearly. His eye, examined with the ophthalmoscope, showed nothing abnormal. He is capable of performing almost any motion, except that he still stoops with difficulty. The muscles of the calf are harder than normal and their electro-muscular contractility is impaired; elsewhere the muscles all act well to the faradic current. He has lately complained a little of headache and of some stiffness and pain at the back of the neck; but for these lingering symptoms he would have been discharged from the hospital. All trichinæ are not, however, encapsuled in his muscles, a few in a piece taken out from the forearm with Hart's trocar were still found alive. But the great majority were encapsuled, and the capsule was full of cretaceous salts.

ON TUBERCULAR PERITONITIS IN CHILDREN.

A Clinical Lecture delivered at St. Bartholomew's Hospital.

By SAMUEL GEE, M.D., F.R.C.P. Lond.,
Physician to the Hospital.

Gentlemen: There are three kinds of tubercular abdominal disease occurring in children: chronic peritonitis, decay of the mesenteric glands, and ulceration of the intestines. These diseases are sometimes associated in different ways, sometimes they happen each alone by itself. They constitute a condition which the common people call "consumption of the bowels," although this term also includes the chronic enteritis which is not tubercular.

My topic to-day is tubercular peritonitis, or, what in the case of children is almost the same thing, chronic peritonitis.

I. *Pathognomonic Signs.*—They are discovered by physical examination of the abdomen, and are of two kinds: indurations and suppurations.

1. *Indurations* are detected by palpation. They have the form of bands and patches, or of lumps and knots. They certainly are present in most cases at some period or other of the disease. They begin to appear within a few weeks

of the onset of the illness. They are more or less obscured by coexisting tympanites; and for this, or some other reason, they are not felt equally well at all times in the same patient. When the abdomen is very tender or resisting, I usually administer chloroform to the child before proceeding to the examination; and I strongly advise you to do the same thing in a doubtful case. The *bands* which I spoke of are commonly transverse, stretching right across the belly, or confined to one side of it. They are felt above the navel, on a level with the navel, or below it—for instance, parallel to Poupart's ligament. They are sometimes remarkably hard. They are mostly about the breadth of the finger, or rather more. The *patches* of induration, like the bands, may be met with anywhere; in a boy now in the hospital, they are felt in the hypogastrium. The *lumps* and *knots* are sometimes very numerous, sometimes there are only one or two. Their size is very different, they often feel like nuts or pips. They differ very much in situation; there is no rule in these matters. The distinction (not always possible) between peritoneal and glandular lumps is to be found in the fact that the former are as a rule more superficial, less deeply seated than the latter.

2. *Suppuration.* Discharge of pus from the navel, due to a local peritoneal abscess, is likewise characteristic. Sometimes there is nothing more than an appearance of pointing, which afterwards subsides, and never goes on to discharge. The navel looks red and swollen, not merely protruded, but its tissues swollen. This sign I believe to be no less characteristic. The pus is sometimes mixed with feces. This is a condition which indicates ulceration of the intestine, and is a very much more dangerous affair than the discharge of pus alone.

Physical examination will also discover signs of either or both of two other abdominal lesions in most cases of tubercular peritonitis. *Tympanites* to a less or greater degree is a symptom almost always present at some period or other of the disease. *Ascites* is less common. In one case of this kind a diagnosis was made possible by the coexistence of phlegmonous scrofulides on the leg, otherwise there was nothing but ascites.

II. *Onset of the Disease.*—Tubercular peritonitis is usually idiopathic, that is to say, it constitutes the disease in and by itself. This is the only case which I consider on the present occasion. I pass by the chronic peritonitis which is secondary to manifest tubercular disease of the lungs, intestines, or other parts.

1. The onset of protopathic tubercular peritonitis is mostly *gradual.* The belly becomes tender, painful, and large; at the same time the health of the child fails; there are emaciation, loss of appetite, and in many cases slight fever. At the beginning examination of the abdomen discovers nothing but more or less tympanites, sometimes associated with a little ascites. The tympanites usually remains moderate, but in some children it becomes excessive, so much so as to cause permanent dyspnœa. The ascites of the onset is small in quantity, and mostly goes away in a few weeks. Afterwards the indurations which I spoke of begin to appear.

2. The onset is sometimes *sudden*, and attended by very great tympanites. The tympanites is sometimes the only abdominal symptom. Sometimes it is associated with vomiting. And sometimes there are also all the signs of acute gastro-enteritis. In my lecture on tympanites last session I narrated a case of this kind—a child suddenly attacked by infantile cholera; violent vomiting and purging, with collapse, algidity, and tympanites. This was the beginning of chronic tubercular peritonitis.

III. *Course of the Disease.*—Suppose the chronic peritonitis established, you will most likely be able to detect one or other of the pathognomonic signs which I spoke of at the beginning. I will now speak of the symptoms which are attend-

ant upon the confirmed disease. Emaciation from the first; appetite bad; vomiting now and then. Action of the bowels uncertain. Diarrhœa, occasional or even more continual, is no proof by itself of the coexistence of intestinal ulceration. Constipation is common, and it goes on in a few uncommon cases to absolute obstruction of the bowels. This obstruction is either temporary, giving way at length to the remedies employed, or it is permanent, and causes the death of the patient. The latter course is well illustrated by a case published by Dr. Wolston in the 10th vol. of the Clinical Society's Transactions. Obstruction of the bowels, although it may have been relieved, is apt to recur. Pain in the belly is sometimes severe, and is sometimes felt on heavy pressure only. The movements of the bowels are sometimes visible, whether there be much tympanites or not. Fever is present at first, but is seldom high; it often ceases altogether after a week or two; sometimes a low degree of fever is constant throughout the whole course of the disease. So that, at the time you see your patient, it may happen that there are no fever or other symptoms of disease, except the emaciation and the abdominal signs already spoken of.

IV. *Termination of the Disease.*—1. *Recovery* from tubercular peritonitis is common. In the course of months, or a year or two, the tympanites disappears, and the indurations cease to be palpable. The patient is left pale and weak, and may continue so for the rest of life. On the other hand, he may regain his original state of health. The most positive proof of recovery from tubercular peritonitis is afforded by Mr. Spencer Wells's case,[1] in which the ascites of that disease resembled an ovarian cyst. Abdominal section was performed; the peritoneum was seen to swarm with tubercles; the intestines, for the most part, were adherent together. Acute peritonitis followed the operation, but the patient recovered, and six years afterwards she was stout, hearty, and well.

2. *Death* from tubercular peritonitis occurs in several ways. A slow exhaustion is common, especially when other forms of tubercular disease come to complicate the case. Increasing and great ascites may be the cause of death. You remember a girl who died in Mary ward after paracentesis for ascites? In her, tubercular peritonitis was associated with highly-marked cirrhosis of the liver, and this is a combination of lesions which I have seen before. Obstruction of the bowels is an uncommon cause of death.

When suppuration has occurred there is an additional danger. Mere pointing sometimes goes away without any manifest discharge of pus from the navel or any other part. When actual discharge of pus from the navel has occurred recovery is still possible. But when there are signs of a fistulous opening into the bowel the case is hopeless, as I said before.

V. *Therapeutics.*—The first thing to mind, in the treatment of tubercular peritonitis, is to keep the abdomen at rest. This can be done only by keeping the patient in bed. I have known a boy, who was slowly recovering whilst he was in bed, undergo a fatal relapse of his disease by being taken up and dressed against orders.

Another part of the treatment consists in putting a flannel bandage round the belly, so as to reach from the hips to the ribs. Much pain in the abdomen is alleviated by hot and moist fomentations, as hot as the patient can bear; linseed meal poultices, flannel fomentations, or, what is usually best, a flannel bag full of bran or camomile flowers, which can be heated in hot water or an oven as often as needful. You may sprinkle the fomentation with laudanum; or you may smear the abdomen with a liniment composed of equal parts of extract of belladonna and glycerine.

[1] Quoted by Dr. Fagge, Guy's Hospital Reports, third series, vol. xx. p. 203.

I need not say much about the necessity of allowing none but the most easily-digestible kinds of food; in short to feed the patient very much as you would feed a baby. Cod-liver oil, if it can be taken, is sure to do good.

For the ascites you may try copaiba resin cautiously, beginning with three or four grains, made into an emulsion, with an equal quantity of compound tragacanth or almond powder, and some water. If this mixture disagree with the stomach you must discontinue it.

When suppuration has set in, the proper treatment is assiduous poulticing.

Hospital Notes.

Hysterical Spinal Affection of Two Years' Duration; Cured by Corrigan's Iron.

Mr. J. D. T. Reckitt, House-Surgeon at the Newark Hospital, records (*Lancet*, Jan. 15, 1881) the notes of the following interesting case:—

Alice D——, aged twenty-five, dressmaker, and single, was first seen on May 20, 1878, when she stated that until two years before, when she had a fall, spraining her back a little, she had always enjoyed good health. She was first attended at her home. She kept her bed, but had a healthy appearance, though the expression of her countenance was melancholic. She had been treated in the hospital, and had also been under treatment at home for what she stated was spinal disease, the treatment including blisters to the spine, various liniments, and, lastly, crutches; but all to no purpose. The nature of the case was suspected to be hysterical, and in answer to inquiries the patient said she had severe pains almost everywhere, not excepting even the ends of the finger-nails, and added to this, a sympathizing mother dilated very largely upon the extreme suffering the patient underwent. She had not been able to walk for several months, but her appetite had continued pretty good. She slept badly, and had much headache. It was therefore determined to apply the actual cautery, and the patient was assured that she would be able to walk in two months' time.

On May 25th, assisted by Mr. J. Sheppard, Mr. Reckitt made six impressions —three on either side—in the spinal fossæ, from the commencement of the dorsal region downwards. The patient complained of considerable pain, and she nearly fainted. It was decided to reapply the iron in a week's time if there was no improvement.

On June 2d she appeared so depressed and reluctant to have a re-application, that it was deferred a week; and accordingly, a week later, six more impressions were made on either side, but below the former. She was ordered to get up.

On the 16th she felt a little better, but still had a little pain and slight headache. She was ordered to try to walk with help.

On the 23d she said she was improving slowly. She was told that probably another application would be necessary.

On July 7th she was downstairs, and had walked several times with help.

On August 20th she presented herself at the hospital, having walked up a distance of half a mile with her sister's aid. Much better, and walked fairly.

On the 30th so much improved that she was discharged.

Remarks.—The apparent total inability of the girl to walk when first seen, and the rapid effect of the heroic measure adopted, would appear to prove that hysteria—or rather, perhaps, malingering in a hysterical subject—was the main feature in the case; and also that the treatment, though somewhat cruel, was the only means to make such an obstinate individual use her ambulatory powers, and to assure her of her ability to do so.

MONTHLY ABSTRACT.

Anatomy and Physiology.

The Circulation in Marrow of Bone and Cerebral Meninges.

KOLLMAN, in a series of investigations into the circulation in the medulla of human bone, has corroborated the statements of Hayer and Rindfleisch that this circulation is not continuous through vessels, but that the minute veins open into the interstices of the tissue. In spite of this interruption, the circulation goes on with perfect regularity. Aqueous solutions of Berlin blue find their way from the veins to the arteries as readily as from the arteries to the veins, and, what is still more remarkable, they find their way from the sub-arachnoid space of the spinal cord, to the spongy structure of the skull, into the sinuses of the dura mater, and into the veins of the skull and of the face. It is conjectured that the communication between the sub-arachnoid spaces and the veins is by means of the Pacchionian granulations. The sub-arachnoid and subdural spaces of the brain are not in direct communication, but the injection readily passes from the subdural space into the periphery of the Pacchionian granulations and so into the venous sinuses. There are also fissures in the inner surface of the dura mater which are openings into the lymphatic canals.—*Lancet*, Jan. 29, 1881.

Some Points in the Anatomy of the Ear.

In a paper which has just appeared in the *Archiv für Anatomie*, by Professor RETZIUS, he states that as the great work of the anatomy of the ear on which he is engaged will take a long time to complete, on account of the trouble and expense of the engravings which are to accompany it, he desires to publish provisionally some of the new facts which he has discovered. In the first place, he some years ago found in the auditory labyrinth of teleostean fishes two small plates on the floor of the utriculus, near the canalis communicans, on which two branches of the cochlear nerve terminate. He considered this structure to be the first indication of the "pars basilaris cochleæ." Hasse acknowledged its existence in fishes, and thought it to be the rudiment or "pars initialis cochleæ." Further researches satisfied Retzius that it was present in the plagiostome fishes, and still more recent researches have enabled him to trace it through the amphibia, through many reptilia, in which it is less developed than in the amphibia, and through the birds, where it is smaller and more rudimentary than in the reptilia, appearing only as a small spot with a few nerve fibres distributed to it, situated on the floor of the ampulla frontalis. No trace of it can be found in the rabbit, cat, or dog, amongst mammals. He has, therefore, changed his opinion, and no longer regards it as the rudiment of the cochlea, but has named it the "macula acoustica neglecta," and the branch of nerve supplying it the "ramulus neglectus." How, then, he asks, does it stand with the true pars basilaris cochleæ—the most important part of the organ of hearing? Since this nerve termination does not represent it, it may be settled that there is no pars basilaris; they only possess the lagena cochleæ. The first traces of the true pars basilaris occur in amphibia.

A second point to which Retzius has directed his attention is the mode of division of the acoustic nerve. He quotes the descriptions given by Henle, Hyrtl, Luschka, Krause, Quain, and Turner. In the works of all these authors the audi-

tory nerve is stated to divide into two chief branches—a ramus vestibularis and a ramus cochlearis. Some authors admit that the vestibularis nerve divides into four branches, which supply the sacculus hemisphericus and the cochlea. Others consider that the cochlear nerve only supplies the cochlea, and that the vestibular nerve gives off five branches. Neither of these statements is correct. The anterior of the two main divisions of the auditory nerve—that is to say, the vestibular nerve—which, by the twisting of the parts really lies posteriorly to the other, divides into three branches, which supply respectively the recessus utriculi, the ampulla sagittalis, and the ampulla horizontalis. The posterior main branch—*i. e.*, the cochlear nerve—divides into three branches, which supply the ampulla frontalis, the sacculus, and the cochlea.—*Lancet*, Jan. 1, 1881.

—

The Mucous Membrane of the Anus.

In the *Journ. de l'Anat. et Phys.*, G. HERMANN has recently published some observations on the structure of the anal mucous membrane. He includes in this term a circular rim from 5 to 12 mm. in depth, reaching from the narrow white ano-cutaneous line pointed out by Hilton, to the ano-rectal line above—a portion corresponding to the internal sphincter and analogous to the red free border of the lips between the skin and true mucous membrane. After pointing out that with the exception of a serous coat on the outside, the structures of this region are the same as those met with in the upper part of the intestine—two layers of muscular tissue, mucous membrane, Auerbach's and Meissner's plexuses,—he enters into fuller detail as to the structure and development of the mucous membrane. The epithelium is squamous and stratified, but columnar in the depressions between the columnæ recti of Morgagni. At the sides he finds pouches and duct-like tubes lined with simple or stratified epithelium, which dip down to the depth of one centimetre into the subjacent muscle and there sometimes branch at their extremities. He considers these to be analogous to the glands found in this situation in animals. It is also suggested that these depressions, duct-like tubes, and the closed follicles found between them play an important part in the production of anal abscess and fistula.—*Lancet*, Jan. 29, 1881.

—

Rigor Mortis.

M. RICHET, in a lecture delivered as one of a course auxiliary to that of the Faculty of Medicine of Paris, has just given a very full and complete *résumé* of the present state of our knowledge of rigor mortis, which has engaged the attention of observers from the time of LOUIS, who in 1752 wrote an essay upon it, in which he pointed out that it was one of the principal signs of death. NYSTEN, in the early part of the present century, demonstrated that cadaveric rigidity is due to the condition of the muscles, since if the ligaments of the joints, the fasciæ, and the aponeuroses, are all divided, rigor mortis persists, whilst it is removed or prevented by division of the muscles or by the separation of them from their attachments. BROWN-SÉQUARD and KÜHNE next examined the phenomena in question minutely, the former showing that it could be removed by the injection of blood into the vessels, and the latter demonstrating that it was essentially a chemical action. It may be stated generally that rigor mortis is never absent; the few cases in which reliable authorities have believed that it has not occurred having probably been instances where it has occurred extraordinarily early or late. It occurs in all animals, both vertebrated and invertebrated. In fishes it takes place almost instantly after death, whilst in frogs, if due precautions be taken, it does not occur until after the lapse of eight or ten days. It has no relation, therefore, to the temperature of the blood of the ani-

mal. The first muscles to undergo rigor mortis appear to be those raising the lower jaw, as the masseter, temporal, and pterygoid, which are very irritable muscles. M. NIDERKORN finds that in 113 subjects rigor mortis was complete at the fourth hour in 31, at the sixth hour in 20, at the fifth in 14, at the third in 14, at the seventh in 11, at the eighth in 7, at the tenth in 7, at the ninth in 4, at the thirteenth in 2, at the second in 2, and at the eleventh in 1. It commences about two hours after death, and in the human subject is usually complete about the fourth hour. It may supervene whilst the animal is still warm, as is seen in those which have been hunted to death. On the other hand, its appearance is retarded by cold, whilst its duration is almost indefinitely retarded by it. A muscle which has become rigid after death becomes still more rigid if exposed to a temperature of 120° F. This increase, according to KÜHNE, is due to the coagulation of the serine and caseine contained in the muscular juice. Mere congelation of a muscle does not cause it to lose its irritability, but it very rapidly becomes rigid when thawed.

The remarkable positions sometimes assumed by men killed on the field of battle have been described by many observers, and demonstrate that rigidity may supervene at the moment of death. BROWN-SÉQUARD has, indeed, recorded a case of adynamic typhoid fever, in which the jaws and limbs became fixed, whilst the heart still continued to beat; and quite lately the same thing has been recorded by M. BOCHEFONTAINE in dogs poisoned with salicylate of soda, and M. RICHET has observed it in animals poisoned with medium doses of strychnia. In these cases all the muscles were rigid and unexcitable, with the exception of the heart; and artificial respiration could only be maintained with difficulty owing to the rigidity of the chest. Division of the nerves supplying a muscle appears to have little or no effect in accelerating the occurrence of rigor mortis, and according to HERMANN, neither exposure to oxygen nor to the vacuum of an air-pump exerts any influence.

In becoming rigid, muscles slightly diminish in volume; they shorten less, at least with moderately heavy weights, than muscles in contraction; they entirely lose their irritability, and their elasticity is greatly impaired. Heat is eliminated whilst rigor is being established.

In regard to the cause of rigor mortis, which is an extremely interesting point, M. RICHET is of opinion that, as KÜHNE originally maintained, it is a chemical process; but this process is a phenomenon not of life but of death. The myosine of the muscle coagulates. The acids, which are constantly being formed and as continuously removed during life, accumulate after death in the muscle, and gradually effect the solution of the myosine, and then the azotized matters undergo decomposition and develop ammonia, which, in its turn, dissolves the myosine, and thus occasions the disappearance of the rigor. Speaking generally, rigor mortis is a chemical phenomenon, characterized by the coagulation of the myosine, and may be considered as the commencement of the death of the elements of the muscle.—*Lancet*, Jan. 22, 1881.

Materia Medica and Therapeutics.

Maize and Maizenic Acid.

The following are the conclusions drawn by Dr. VAUTHIER, in a brochure entitled, *Etude sur le Maïs (Zea Maïs) et l'Acide Maïzenique (Archives Méd. Belges*, August, 1880): 1. The action of Zea maize is always favourable in all

affections of the bladder, whether recent or chronic. 2. Maizenic acid is the active principle of the stigmata of maize, and it alone contains the therapeutic properties. 3. The diuretic action is not constant; it is met with in cases of acute traumatic cystitis, and in cases of retention, but here the improvement in micturition is due to the recovery of the affected organs, and not directly to the action of the maizenic acid. 4. The best results are observed in uric and phosphatic gravel, in acute cystitis, whether simple or due to gravel, and in mucous or muco-purulent catarrh. 5. In the cases observed by the writer, the ordinary remedies for these affections had already been employed without benefit, while the maize never failed to effect a cure. In connection with the maize, simple and medicated vesical injections were employed. 6. Maizenic acid, moreover, has the power of dissolving calculi by its chemical action; and not only vesical calculi, but also all the other calcareous concretions that are met with in the human system. Hence its use seems indicated in cases of gout and rheumatism, as well as in affections of the urinary organs. The preparations used by the author were the infusion (10 parts of corn-silk to 100 of boiling water, with syrup *ad libitum;* dose, a tablespoonful every two hours), the extract in doses of one and one-half to three grains, and maizenic acid in doses of one-eighth of a grain in pill or mixture.—*London Med. Record*, Jan. 15, 1881.

Anæsthesia by the Application of Chloroform to the Skin.

We lately described the interesting experiments of Dr. Brown-Séquard on the effect of the application of chloroform to the skin on the functions of the central nervous system. It has been objected that the effects might possibly be due to the inhalation of some of the chloroform vapour. He has therefore repeated his experiments, and with the precaution of making the animal breathe air from another floor of the laboratory than that in which the experiments were made, its head being placed within a tube. The results obtained were the same as those already described, the only difference being that the period of excitement which usually precedes that of complete resolution, was a little longer than in the experiments already published. During this period, which is frequent, although not constant, the respiratory and cardiac movements are more rapid and more energetic. The animal cries and is disturbed—it appears hyperæsthetic, and its rectal temperature is raised a fifth or a quarter of a degree Centigrade.

Dr. Brown-Séquard, in a fresh series of experiments, has ascertained that the influence of chloroform on the mucous membranes is, as a rule, much more rapid and energetic than when applied to the skin. In these observations also the animals (dogs, cats, rabbits, and guinea-pigs) were made to breathe, by means of a tube fixed in the trachea, air coming from a distant part of the laboratory. Inhibition of the heart and respiration was invariably produced in a very brief, though variable time. Moreover, the loss of sensibility, of reflex action, and general resolution, with arrest of the exchange between the tissues and the blood, were frequently observed almost immediately after the application of the chloroform to the mucous membranes of the nose and larynx, or when it was poured into the mouth of guinea-pig or rabbit. But, strange to say, the application of chloroform to the posterior part of the mucous membrane of the mouth of the dog, or to the surface of the pharynx, always produced the opposite effect to the inhibition observed in the other animals. Respiration is greatly augmented, one dog, for instance, breathing 160 times a minute. Thus the effect in the same animal is altogether different when the chloroform is applied to the laryngeal mucous membrane, than when it is applied to the adjacent mucous membrane in the pharynx and mouth.

The influence of chloroform poured into one nostril upon the diaphragm and phrenic nerves is exactly the same as that produced when it is applied to the side of the thorax or to the shoulder. There is a loss of the equilibrium between the action of the two halves of the diaphragmatic apparatus; the phrenic nerve and the half of the diaphragm on the side corresponding to the nostril irritated become more energetic both in the degree and in the duration of their action, after the thorax has been opened, while those on the other side present the opposite condition.

Chloral hydrate, even in the most concentrated solution, when applied to the skin, does not usually produce any of the anæsthetic or other effects which follow its injection into a vein or beneath the skin. This is, however, not true when a large area of the skin is irritated by anhydrous chloral. The effects of this are perfectly analogous to those of the application of chloroform. The only differences are that the chloral acts more slowly, but causes death more readily; that it causes pulmonary, renal, and intestinal hemorrhages more frequently than chloroform, and that it produces abundant secretions from various abdominal glands, and so causes diarrhœa, an effect which is never produced by chloroform. Chloral seems to cause glycosuria, which chloroform never does, and is apparently absorbed by the vessels of the skin to a much greater extent than chloroform. Inhalations of anhydrous chloral or its application to the skin, do not produce anæsthesia except at the moment of death. In the guinea-pig especially, which is rendered anæsthetic so readily by the inhalation of a very small quantity of the vapour of chloroform, the inhalation of chloral has very little anæsthetic effect.—*Lancet*, Jan. 29, 1881.

—

Gelsemium as a New Antipruritic Remedy.

Dr. L. DUNCAN BUCKLEY recommends (*New York Medical Journal*, Jan. 1881), gelsemium as an adjuvant for the relief of itching in certain cases, especially eczema in adults. He gives it in increasing doses, repeated every half hour or every hour, until the pruritus is relieved. He begins with ten drop doses of the tincture and has often found some measure of relief after the first or second dose.

—

On the Action and Uses of Certain Remedies employed in Bronchitis and Phthisis.

Dr. T. LAUDER BRUNTON makes the following interesting communication to the *Lancet* (Jan. 1, 1881), on this subject:—

In both bronchitis and phthisis the first symptoms that attract notice are cough and expectoration, and the first remedies that claim our attention are the so-called sedatives and expectorants. Cough consists in deep inspiration, closure of the glottis, and violent expiratory effort, by which the glottis is forcibly opened by the compressed air, which carries with it, in its exit, mucus or other matters which may have lodged in the lungs or respiratory passages. The nervous centre for this act lies in the medulla oblongata. It is bilateral, and situated on each side of the central raphé. It is excited into action reflexly by irritation of the respiratory branches of the vagus distributed to the glosso-epiglottidean folds, to the whole interior of the larynx, to the trachea, especially at its bifurcation, and to the bronchi, and the substance of the lung itself, as well as the pleura when it is inflamed. Irritation of the internal auditory meatus at the point to which the auricular branch of the vagus is distributed also causes coughing, and so also may irritation of the liver and of the spleen. As coughing is a reflex act, excited by irritation applied to a sensory nerve, and reacting through a nerve centre upon

the respiratory muscles, it is obvious that it may be lessened, either by removing the source of irritation or by diminishing the excitability of the nervous mechanism through which it acts. Both methods are employed in medicine. One of the commonest is that of lessening irritation by the use of glutinous and saccharine substances. These have in themselves little or no action upon the nervous mechanism. They do not pass down to the bronchi, or lung substance, so that they can have no direct effect upon the mucous membrane there, nor have they, so far as we know, any effect upon it after they have been absorbed into the blood; and yet one of the commonest observations is that glutinous and saccharine substances have a very great power to allay cough when applied to the back of the throat, even in cases where we know that inflammation and consequent irritation exist in the respiratory passages below the glottis, at a point which the mucilaginous substances cannot reach. The probable explanation of this action of such substances as marshmallow lozenges, jujubes, consisting of gum and sugar and Spanish liquorice, is that the irritation which occasions the cough exists at the root of the tongue and around the fauces, as well as in the trachea, bronchi, or lungs, the combined irritation rendering the cough worse than either the one or the other alone would do; and, therefore, if we soothe the tongue and fauces we relieve the cough, even though the irritation in the bronchial tubes or lung may remain as before. The power of such substances as those mentioned to relieve cough depends, no doubt, to a great extent either on their covering the inflamed and irritable surface directly with a mucilaginous coat, and thus protecting it from the action of the air or from irritation by other substances passing over it, or by exciting an increased flow of saliva or mucus, which has a similar effect. At the same time we cannot deny the possibility of their having other actions, though with these we are at present unacquainted. The use of the mucilaginous substances containing opium or other sedatives, which we know under the name of "linctus," is a more complicated one. In them we have the soothing action of the mucilaginous compound, combined with the local sedative action of morphia, chloroform, or hydrocyanic acid upon the inflamed or irritable mucous surfaces at the root of the tongue and back of the throat, and this renders even their local action more powerful than that of a mucilaginous substance alone. Such drugs as opium, hydrocyanic acid, and chloroform have a certain amount of local action upon the peripheral ends of sensory nerves, and lessen their sensibility to impressions. When they are applied to the ends of the nerves only for a very short time, as they are when we swallow these drugs in a liquid form, their local action is comparatively slight. It is much greater when they are taken in a mucilaginous vehicle, which, adhering to the irritated mucous membrane over which it passes, keeps the sedatives in contact with it for a longer time, and thus allows them to exert a more powerful action. But the sedatives which we give to relieve cough are not unfrequently administered in the form of solution, and then, though their local action must be comparatively slight, they still lessen a troublesome cough. Their action here is a different one from that which we have just discussed, but it is possessed by the sedative whether given in the form of linctus or of solution. In either way it is swallowed by the patient, absorbed from the stomach and intestines into the circulation, and carried by the blood to the medulla oblongata, and also to the inflamed mucous membranes, in which the blood circulates freely, just as well as in other parts of the body, although here its action is likely to be very much less than if it were applied for a length of time directly, as in the shape of the linctus; but, as we have mentioned, the linctus can only be applied to the back of the tongue and throat, and the source of irritation of the afferent nerves may be in the bronchi or in the lung itself. Here, no doubt, a linctus cannot penetrate, but we may to a certain extent act

locally upon the nerves by the use of spray and inhalation. Some of these, such as the vapour of conium and the vapour of hydrocyanic acid, are intended to lessen the irritability of the sensory nerves in the respiratory passages, and thus lessen cough. Others, such as the spray of ipecacuanha, and inhalation of essential oils and terebinthinous substances, have probably a different action, and do not lessen the irritability of the sensory nerves in the respiratory passages, but alter the nutrition of the mucous membrane in such a way as to diminish the irritation which the abnormal condition of the membrane exerts upon the nerves. When the irritation is situated in the larynx, as in cases of laryngeal phthisis, one of the best means of relieving it is by applying the sedatives locally, whether by means of a brush, or, what is perhaps still better, by blowing it, in the form of a powder, directly upon the irritated surface. A useful application in laryngeal phthisis consists of a mixture of morphia and starch, in the proportion of about one-sixth of a grain of morphia to two grains of starch. This mixture is introduced into a glass tube, of a proper shape, and is blown down the throat at the instant that the patient takes a deep inspiration. The powder is thus distributed over the interior of the larynx, and exerts its local sedative influence upon the irritated surface, as well as a general sedative effect upon the central nervous system after its absorption.

This brings us to the second mode in which sedatives relieve cough. After their absorption into the blood, in whatever manner they may have been applied, they are carried to the medulla, and there lessen the excitability of the nerve centre through which the reflex act of coughing is produced. In large doses their sedative effect may be so great as to endanger life, and the caution is given in every text-book, and by every teacher, that respiratory sedatives such as opium should be carefully administered to persons suffering from bronchitis with profuse expectoration, lest the irritability of the medulla should be so far diminished that it will no longer respond even to a powerful stimulus from the lungs, and the secretion may consequently go on accumulating until when the patient awakes the respiratory passages are so clogged with mucus that no effort which he can make is sufficient to clear them, and he dies of suffocation. By administering them in smaller quantities, however, the effect of respiratory sedatives may be graduated so as to diminish cough without any risk of causing death, and their effect would be exceedingly beneficial if they acted only upon the respiratory centre. Unluckily, however, this is not the case, and the most powerful of all—viz., opium—not only influences the respiration, but the digestion. It diminishes the cough, but sometimes, also, it diminishes the appetite, and may interfere with the proper action of the bowels. When this is the case, we are obliged carefully to steer between two dangers: (1) the injurious effects of the cough itself, and (2) the injurious effect of disturbed digestion. If we leave the cough alone, it exhausts the patient, for the muscular exertion involved in a violent fit of coughing is very considerable indeed, and the muscular effort exerted by a patient with a bad cough during the twenty-four hours is really more than equivalent to that of many a man in a day's work. Nor is this all. Any one who watches the face of a patient during a violent fit of coughing will see the skin become flushed, and then dusky; the veins in the forehead and in the jugulars swell up, and become so tense that they seem as if about to burst; so that there is both venous engorgement and interference with the respiration. But what we see in the face takes place elsewhere. The same tension which we see in the jugulars is also present in the right side of the heart, in the vena cava, and in the portal system; for the portal vein has no valves, and the increased tension is transmitted backwards to the veins of the stomach, spleen, and intestines. By and by this all begins to tell upon the heart and upon the digestive system, as well as, to some extent,

upon the kidneys. The stomach becomes congested, and we have loss of appetite, nausea, and vomiting. The patient, too, is kept awake, and we have nervous exhaustion, or loss of sleep, added to the weariness caused by the muscular exertion, and to the depression occasioned by digestive disturbance. These are what we have to fear: on the one hand, continuous coughing; on the other, we must avoid the digestive disturbance produced by our sedatives; and the duty of the physician is, so far as possible, to relieve the cough without disturbing the digestion. Numerous combinations have been devised, and are found to be, empirically, of very great service. If we take one of them and attempt to analyze it, we shall find that its components are such as to diminish the excitability of the respiratory centre, and at the same time to lessen the injurious effect of the sedatives upon the stomach. Such a one is the following mixture: Solution of hydrochloride of morphia and dilute hydrocyanic acid, of each eighteen minims; spirit of chloroform and dilute nitric acid, of each one fluidrachm; glycerine, three fluidrachms; infusion of cascarilla or infusion of quassia, two fluidounces; a sixth part to be taken three or four times a day.

In this mixture, which in its essence was much used by the late Dr. Warburton Begbie, of Edinburgh, to relieve the cough in phthisis, we find the sedatives morphia, hydrocyanic acid, and chloroform, to lessen the excitability of the respiratory centre; we find glycerine, which will tend to retain the sedatives for a longer time in contact with the back of the throat, and will also act to some extent as a nutrient. We have combined with these nitric acid and infusion of cascarilla or of quassia, which have so-called tonic (?) action upon the stomach. In what this effect precisely consists we cannot at present say, but we may imagine that it will in some way partially counteract the effects of the congestion which the cough produces, and at the same time we know that they have the power of exciting appetite, and they will thus in a great measure counterbalance the injurious effects of the morphia upon digestion. Nor is this all. The nitric acid, as I shall shortly have to mention, has a very definite effect indeed upon the secretion in the lungs themselves; and this brings us to the consideration of another part of our subject—viz., the effect of drugs upon the secretion and nutrition of the lungs, by which they tend to restore the healthy condition of the bronchial and pulmonary tissues, and thus diminish coughing.

First of all, then, we must consider those drugs which lessen congestion. If a person, hastily eating or drinking, get a crumb of bread or a drop of fluid down the larynx, or into the wrong throat, as it is termed, he suddenly begins to cough violently, and the cough continues until the source of irritation has been removed. If the irritation has been violent he may give a few coughs after the crumb has been coughed up, although the primary source of irritation—namely, the crumb—has disappeared; but the congestion which it occasions still remains for a short time, and acts as an irritant. If a person suffering from disease of the mitral valve makes any sudden exertion, he is very likely to bring on a cough, which, however, quickly subsides after a short rest. The cough here is not due to inflammation of the mucous membrane, but simply to congestion, and when the congestion disappears the irritation goes with it. In cases where we have inflammation of the respiratory vessels actually present, as in persons suffering from bronchitis, the congested condition of the membrane is a source of considerable irritation, and we frequently notice that such persons, on going out into the cold air, may cease to cough, but again begin to cough violently when they return from the cold air into the warm room. The reason of this is that the cold air has acted upon the congested vessels of the respiratory passages in a somewhat similar way to what it does upon the vessels of the face; it causes them to contract, and the congestion being thus diminished the cough is lessened. When the patient

goes into the warm room the face, which may have been pale while he was exposed to cold, flushes up with the heat, the vessels of the respiratory passages also became engorged, and the increased congestion causes irritation, bringing on the cough. In other cases, again, we notice that, just as the face becomes pale when exposed to cold, it shortly afterwards becomes flushed, although the application to cold continues. A person suffering from bronchitis, on going into a cold room, will begin to cough violently, the cold here increasing instead of diminishing congestion.

The pulmonary capillaries have great contractile power. Ten years ago I made some experiments, which I have not yet published, on the subject. I found that on the application of cold to the lung of a frog, when placed under the microscope, the capillaries would contract to two-thirds of their former diameter. We have, however, very few observations on the action of drugs upon the pulmonary circulation, the difficulties in the operative procedure being very considerable. I have observed that muscarin appears to have a power of contracting the pulmonary vessels, and that this effect is abolished by atropia. I am unaware, at present, of any other observations on the action of drugs upon the pulmonary circulation. Circumstances have prevented me from studying the recent researches on this subject in the way I should have wished, while drawing up this paper. From its power of contracting the vessels in other parts of the body, we should expect that digitalis would have a similar action upon the lungs; and we find, in looking over Beasley's "Book of Prescriptions," that digitalis has been used in pulmonary affections—as for example, in the following draught, employed by Sir A. Crichton in acute phthisis: lemon-juice, half an ounce; carbonate of potash, to saturation; decoction of sarsaparilla, ten drachms; tincture of digitalis, ten to thirty minims; acacia mucilage, ten drachms; to be taken every sixth hour. In such a prescription as this we have the tincture of digitalis, which will, in all probability, by contracting the vessels, diminish the pulmonary congestion and lessen cough. It is combined with carbonate of potash, and the effect of potash upon the lungs is very marked indeed. For my knowledge of its action I am indebted to Dr. Andrew Clark. Its action is perhaps best noticed in a patient suffering from consolidation and softening of a limited portion of one lung. When such a patient is in ordinary health, one may observe, on a stethoscopic examination, crepitant râles, limited to one spot. When he catches cold, one may hear, in addition to those, dry râles extending for some distance around the irritated spot, and the cough at the same time becomes more frequent and troublesome, while there is very little, if any, expectoration. If potash be now given alone, or, still better, in combination with a vegetable acid, the dry râles subside, and are replaced by moist ones, which in the course of a day or two, as the potash is continued, alter in character, giving one the impression of their being caused by less viscid fluid. At the same time the expectoration becomes more copious, and the cough less frequent and less troublesome. Now is the time to alter the treatment, and for the potash to substitute nitric acid. If this be given too soon the cough, which had begun to get easier, will again become drier and harder, but if it be administered at the proper moment the cough becomes still less troublesome, the expectoration diminishes, and the moist râles disappear from the neighbourhood of the consolidated part of the lung, although they may still remain, as before, in that part itself. Potash, then, has a very marked effect in rendering the pulmonary secretion more fluid and abundant, while nitric acid has an opposite effect. As in many cases we wish to diminish the secretion rather than increase it, it is nitric acid rather than alkalies which we employ for long periods in the treatment of phthisis, as we have already seen in the modified formula of Dr. Begbie's phthisis mixture.

One of the most powerful expectorants is simply a little warm food in the stomach, and in cases of chronic bronchitis, in which the patients complain of violent coughing immediately after rising, one of the best expectorants is a glass of warm milk, either with or without a little rum, and a biscuit or a piece of bread about a quarter of an hour before they get up. A little warm beef-tea will have a similar effect. After taking this for a short time they generally tell you that the sputum comes away much more easily than before, and they are not so much exhausted by it. But perhaps the remedy, *par excellence*, not only in cases of phthisis, but in chronic bronchitis, is cod-liver oil. Persons suffering from long-standing chronic bronchitis will often come to the hospital to beg for cod-liver oil, saying that it eases their cough far more than any cough mixture. Other oils or fats have not this power to the same extent as cod-liver oil. We cannot say positively what the reason of this may be, but I think there is no doubt about the fact. My own belief is that cod-liver oil is more easily assimilated than other oils, and not only so, but more easily transformed into tissues themselves. Whether it owes this property to its admixture with biliary substances, or to its chemical composition, we cannot say. In his book on "Fat and Blood, and how to make them," Dr. Weir Mitchell quotes a remark made by an old nurse, that "some fats are fast, and some fats are fleeting, but cod-liver oil fat is soon wasted." By this she meant that there were differences in the kinds of fat accumulated under the subcutaneous tissues of men, just as there are differences in subcutaneous fats which accumulate in horses. The horse fed on grass soon gets thin by hard work, while fat laid on when the horse is feeding on hay and corn is much more permanent. Persons fattened on cod-liver oil soon lose the fatness again, and this, I think, points to the power of ready transformation which the oil possesses. Supposing that it does possess this power, we can readily see how very advantageous it will be. In chronic bronchitis, and in catarrh and pneumonia, we have a rapid cell-growth, but want of development. The cells lining the respiratory cavities are produced in great numbers, but they do not grow as they ought to do. They remain, more or less, lymphoid cells, instead of developing into proper epithelium. They so rapidly form, and are thrown off so quickly, that they have not time to get proper nutriment, and if they are to grow properly we must supply them, not with an ordinary kind of nutriment, but with one which is much more rapidly absorbed, and is capable of much more rapid transformation in the cell itself than the usual one. This power is, I believe, possessed by cod-liver oil, and to its quality of nourishing the rapidly-formed cells in the lungs in cases of bronchitis and catarrhal pneumonia I believe its great curative power is owing.

The next subject we will consider is the action of some drugs in the vomiting associated with cough. The action of vomiting, like that of coughing, is reflex; the nervous centre for it is also in the medulla oblongata, closely associated with the respiratory centre, and it is excited by various afferent nerves, the chief of them being the branches of the vagus distributed to the stomach. When congestion of the stomach is present, these become irritated, and we get loss of appetite, nausea, and vomiting. Like coughing, vomiting may be prevented by the removal of the irritant. For example, where the irritant is indigestible food, the vomiting ceases after the ejection of the offending substances. When the irritation depends on inflammation of the walls of the stomach, it may be soothed by sedatives having a local action upon the nerves, such as ice and hydrocyanic acid, or by drugs having the power of lessening the irritability of the nerve centre of the medulla, such as opium. In the chronic vomiting of phthisis, all these drugs may be employed, but there is one other which has been useful in this affection, and which probably has no effect either upon the nerve centre or the nerve ends

This is alum. Its mode of action probably is that by its astringent power it contracts the vessels of the stomach, and thus lessens the congestion and consequent irritation produced by the continued coughing in the manner already described.

Eruption Produced by Chloral.

Dr. Gee, Physician to St. Bartholomew's Hospital, has recently had under his care in the wards a girl, seventeen years of age, with chorea, for which chloral hydrate in frequently-repeated doses was prescribed. During the third week of its administration, a papular eruption of a dusky hue, surrounded by much cutaneous redness, was produced on the forehead, face, chest, and extremities, in arrangement partly crescentic and partly confluent. The eruption consisted essentially of a combination of lichen and erythema papulatum, and was attended with some increase of temperature.—*Lancet*, Jan. 1, 1881.

Medicine.

The Treatment of Diphtheria.

This is a subject of almost exhaustless interest, and therefore any well-observed facts in connection with it deserve notice. Some recent numbers of our contemporary, the *Berliner Klinische Wochenschrift*, contain papers which treat of it; and as the remedies proposed are simple and readily obtainable, and more especially as they appear to have been very efficacious, we shall briefly analyze the papers for the benefit of our readers.

Dr. G. GUTTMANN, of Cannstatt, proposes the use of pilocarpin. He reports in No. 40 of the *Berliner Klinische Wochenschrift* that he has used it during the past fifteen months, and, as the result of his present experience, is inclined to regard it almost as a specific. He feels unable to decide whether the local or the general manifestations of diphtheria are the primary. He inclines, however, to the belief that the local symptoms precede and give rise to the subsequent general condition, for, as a rule, and with few exceptions, the general disease is in proportion to the severity of the local lesion, pharyngeal or otherwise, and, moreover, recovery sets in as soon as the local signs of the disease begin to abate. And professional attention has long and largely been devoted to the means by which false membranes and other local conditions may be got rid of; hence the use of paintings, caustics, gargles, and inhalations. Unfortunately their application is not always easy, and often increases the local irritation. The knowledge of the physiological action of pilocarpin has led Dr. Guttmann to try it in diphtheria. As is well known, it increases bronchial secretion, and it was thought that in this manner the diphtheritic membrane would be loosened and got rid of. The result seems to have been extremely satisfactory. In April, 1879, Dr. Guttmann was called to attend a family of nine persons ill with diphtheria, of whom three were in a serious condition. Pilocarpin was ordered in medium doses, so that about one grain was taken during the day (gramme 0.05). Within a few hours a copious salivation was going on, and "the diphtheritic membranes swam away in the flowing saliva." Quinine was ordered internally, as well as a gargle of lime-water and pepsine. All these nine cases recovered within two to four days.

During the following fifteen months he treated sixty-six cases of diphtheria on the same plan. Of these fifteen were very severe cases (under other methods of treatment he considers that at least two-thirds of the patients would have died),

eighteen were slight, and the remaining thirty-three of medium severity. *They all recovered;* the most severe cases only lasting eleven days, while the majority were cured within two or three days. The earlier cases of this series had other treatment at the same time—quinine, etc.—but the later cases were treated solely with the pilocarpin. In speaking of the cases as diphtheria, Dr. Guttmann took especial care to exclude other forms of disease; in most of the cases there was a clear history of infection, and as diphtheria was constantly occurring, he would be quite familiar with it; thus we may take it for granted that there is no error as far as diagnosis is concerned. Many professional colleagues in his own neighbourhood tried the remedy and found it efficient. The drug was administered internally; within a short time it produced an active flow of saliva, by means of which the false membrane was loosened, the inflammatory infiltration also lessened, and the intense redness gave place to a more normal colour. His formula for children is as follows: ℞. Pilocarpini muriatici 0.02–0.04, pepsini 0.6–0.8, acid. hydrochlorici gtt. ij, aquæ destill. 80.0; a teaspoonful every hour. For adults the dose is about double. If the physiological action of the drug does not manifest itself within a short time, increase the dose.

Dr. Bosse, of Domnau, relates in No. 43 of the same journal how the accidental administration of a spoonful of turpentine to a child in the last stage of diphtheria apparently saved its life, all other remedies having previously failed. This led him to make further trials with the drug; and he reports that he found it very serviceable. His first case was a boy, ten years of age. Carbolic acid had been placed in a saucer in the room for the purpose of disinfecting the air; but the odour was intensely objectionable to the boy's parents, and so turpentine was substituted. In the hurry and excitement attendant on the illness, a tablespoonful of the turpentine was given to the boy instead of his proper medicine. Both were contained in very similar phials. The turpentine does not appear to have caused any very great discomfort, and as the mistake was quickly perceived a quantity of milk was given in order to palliate it. After a while the boy became quieter and fell asleep, his breathing having previously been extremely laboured. On the following morning he appeared very much better, and he finally recovered; there had been no ill effects from the dose, either on the intestinal canal or on the urinary system. The circumstance produced a vivid impression on Dr. Bosse, who at first rather feared that the effect might be *post* rather than *propter hoc*. However, being placed in a district where diphtheria was endemic, he decided to put the treatment to the test, and in the course of a short time he tried it in twenty-three cases, all children from two to twelve years of age. The younger children took two drachms, the elder ones three drachms, of rectified turpentine. It was given pure, and forced down if necessary. The children were allowed as much milk afterwards as they cared to drink. In only one case was there vomiting; in all the others the oil was well borne. Dr. Bosse's usual treatment (chlorate of potash in lime-water with syrup of Peruvian balsam, and locally painting with Peruvian balsam) was continued after the turpentine. Within twenty-four hours, on examination, the false membranes were found broken and loose and raised. In four cases a second dose of turpentine was given. The whole of the twenty-three cases were well within forty-eight hours of the appearance of the diphtheritic patches. Of sixty-three other patients so treated, four died; but as they were all at a distance, Dr. Bosse was not only unable to control the treatment, but also to report very accurately on the cases. He says, "If sceptics might wish to argue that the above twenty-three cases were all of a mild variety, there was proof at least that the remedy considerably shortened the duration of the disease."

In the same number of the journal, Dr. Annuschat, of Liegnitz, after re-

porting on the uselessness, in his hands, of the ordinary remedies (chlorate of potash, salicylic acid, benzoate of soda, inhalations of lime-water, and of lactic acid) in several cases of severe and very typical diphtheria, among children for the most part, refers to a case in which the first local appearance was in the vagina; it was accompanied by severe constitutional symptoms. The following is the case: The pharynx was normal; proceeding from the right side of the vagina, and involving the thigh, there was a diphtheritic ulcer eight centimetres broad; the surrounding parts were œdematous, while the edges of the sore were raised and rigid, the sore itself being correspondingly depressed; it had a white, glossy appearance. Solid nitrate of silver was applied, but the sore continued to extend very widely. Under these circumstances it was felt necessary to try other measures: cyanide of mercury was decided upon—two grains of the mercury in three ounces and a half of peppermint water, of which one teaspoonful was given every hour throughout the day and night; water dressing was applied locally to the vagina. Within twenty-four hours a remarkable change took place, and on the third day the sore was granulating healthily. The mercury, which had been taken regularly, was then discontinued. Two other successful cases of vaginal diphtheria are likewise reported. Shortly after the occurrence of these cases, an outbreak of pharyngeal diphtheria took place, affecting some 120 children under fifteen years of age. They were all treated with cyanide of mercury internally, and a spray of benzoate of soda solution locally. Stimulants also were freely prescribed. Of the 120 patients, 106 recovered, and 14 died.

The preceding records are certainly not a little remarkable; but diphtheria, in a typical as well as severe form, is known to occur in certain districts of Prussia, and thus the practitioners of those districts must be well acquainted with its clinical features, and are not likely to be misleading in their statements. We have transcribed them as we have found them, and must leave it to those whom it concerns to verify them or otherwise. This much we are all aware of—that diphtheria is a very serious disease, and that our most approved remedies (so called) not infrequently fail to produce any effect upon it. In such cases it would, no doubt, be hard to try new remedies, and failing, to condemn them as useless; but if, tried as an *ultimum refugium*, they should prove of service, it would greatly enhance their claims to further and more extended trials in less desperate cases.—*Med. Times and Gazette*, Jan. 22, 1881.

The Temperature in Tubercular Meningitis.

Dr. Jules Turin, in an interesting article on Tubercular Meningitis, in the *Jahrbuch für Kinderheilkunde*, vol. xvi., sums up the question of temperature as follows: 1. Tubercular meningitis is always accompanied by a rise in temperature in one or other of its stages, but very seldom during its entire duration. (The stages are given according to Dr. Wyatt, who, as is well known, first described the disease.) 2. In a few cases only does the disease begin with a sudden rise of the bodily heat, as in some forms of acute disease. 3. The thermometric results are extraordinarily variable, so that it is quite impossible to establish any typical temperature curve. 4. In uncomplicated cases of tubercular meningitis the temperature rarely exceeds 102.2° F.; it generally varies between 100° F. and 102° F., but it may also sink some degrees below the normal. 5. The most common type is the remittent, with the usual day fluctuations. The variations within twenty-four hours are normal, or more than normal; sometimes they are very irregular, with more or less sudden rise or fall at any stage and at different periods in the twenty-four hours. 6. If the tubercular meningitis is the terminal affection of some previously existing febrile disease—as, for instance, a

coxitis, or any bone- or other joint-lesion,—the average temperature will be higher than in other cases; but, in other respects, the course of the disease will be unaffected. 7. In the cases with acute general miliary tuberculosis the febrile exacerbations are more considerable and the variations more marked.—*Medical Times and Gazette*, Jan. 15, 1881.

—

Epilepsy and its Differential Diagnosis from Hystero-Epilepsy.

In view of those not infrequent cases of hysteria closely simulating epilepsy, and of epilepsy occurring in hysterical patients, we think our readers will peruse with some interest a short account of an address delivered on the above subject by Professor von STOFFELLA, of Vienna, to the Medical Society of Vienna. Professor von Stoffella employs the term epilepsy as a collective expression for the sum of certain symptoms. Following Nothnagel he believes that essentially it consists in a peculiar condition, "a change *sui generis*," in the central nervous system, which change is characterized by increased irritability, more especially of the pons and the medulla oblongata, the reflex vaso-motor and muscular centres situated in these portions of the brain reacting to the slightest stimulus. This epileptic condition or "epileptic alteration" (Nothnagel) is to be distinguished from the prolonged comatose condition of rapidly consecutive epileptic attacks—the *status epilepticus*, or *état epileptique*, *état de mal* of French writers. Loss of consciousness more or less complete is an absolutely constant symptom of epilepsy; while, on the other hand, the tonic and clonic convulsions may fail, as in the *petit mal* of French writers, which is undoubtedly epilepsy.

Trousseau speaks of certain cases, which he would designate by the term "partial epilepsy," where the epileptic convulsions are confined to the spot in which the aura originates, and there is no loss of consciousness; and to this class he would refer many cases of angina pectoris. Professor von Stoffella practically refuses to admit these cases into the category of epilepsy, and recognizes no fundamental analogy between angina pectoris and epilepsy. Proceeding with his definition, Professor von Stoffella remarks that epilepsy is in its nature a chronic disease; and it therefore does not include those cases where epileptiform convulsions are caused by an irritation—*e. g.*, the eruption of teeth in children, —and subside at once on the removal of that irritation. So also it does not include those cases of epileptiform convulsions resulting from cerebral anæmia or hyperæmia caused by coarse cerebral disease, such as profuse cerebral hemorrhage, large tumours, acute hydrocephalus, emboli, etc. Such epileptiform attacks are distinguished from epilepsy by the frequent absence of a stage of tonic spasm, by the longer duration of the convulsions, and sopor, and by the frequent absence of laryngeal spasm.

In epilepsy no coarse change is found in the pons or medulla oblongata; and possibly, as Schröder van der Kolk says, the dilated capillaries, the granular albuminous exudation, and corpora amylacea are the results rather than the anatomical causes of the disease. This we must note, however, does not imply that coarse brain disease may not lead to the "epileptic alteration" above mentioned, for affections of the cortex, and more especially tumours of the convexity of the cortex frequently cause a unilateral epilepsy.

In the differential diagnosis of pronounced epilepsy and hystero-epilepsy, the loss of consciousness in epilepsy is not absolutely distinctive, for there are undoubted cases of hystero-epilepsy where the consciousness is clouded or even entirely lost. The following are important points of distinction: 1. The aura of hysteria is generally the *globus hystericus*, a feeling as of a ball pressing on the umbilical and epigastric regions, and rising gradually to the throat, where it

causes a feeling of constriction. We may notice that this is no imaginary feeling, but is really a spasmodic constriction of the œsophagus passing gradually upwards to the pharynx. The aura of epilepsy is described in various ways, like a breath of wind or like formication. However short the hysteric aura may be, it is of longer duration than the aura of epilepsy, which is of lightning rapidity. 2. The hysteric attack is more noisy; the movements more extensive, not confined principally to one half of the body, as is frequently the case in epilepsy; and the attack frequently ends in a fit of weeping or laughing. An epileptic, on the other hand, after the cry with which the attack usually begins, is absolutely silent, and rarely moves from the spot where he drops down. 3. Charcot has observed that in a tonic hysteric attack, even if slight, the temperature rises just as in an epileptic attack, about 2° Fahr. But in a case of repeated epileptic attacks (*e. g.*, fifteen to twenty in twenty-four hours) the temperature will rise to 41° Cent. or higher (105.8° Fahr.); while, however often the epileptiform hysteric attacks occur, the temperature does not rise above 38° Cent. or thereabout (100.4° Fahr.). For example, in a case of hystero-epilepsy recorded by Charcot, where the attacks lasted over two months, numbering one day as many as 150 to 200, with complete loss of consciousness, the rectal temperature throughout was 37.8° Cent. (100° Fahr.), with short exceptions of 38.5° Cent. (101.3° Fahr.). In only one fatal case of hystero-epilepsy recorded by Wunderlich did the temperature rise immediately before death to 43° Cent. (109.4° Fahr.). 4. Romberg mentions that the pupils in hysteria are sensitive to light, while in epilepsy they are absolutely insensitive; and Hasse notes that the hysteric attack lasts longer than the epileptic. 5. In addition to these, Professor von Stoffella remarks on a peculiarity in the pupils of epileptic patients (one or both sides) which he has lately observed, and which we do not remember having seen elsewhere noticed. They are either abnormally wide or abnormally narrow, and exceedingly slow in reacting to light. In the cases in which he has observed this peculiarity—numbering four—it has disappeared under the use of bromide of potassium. He explains the condition by the persistence of the temporary disturbance of circulation in the corpora quadrigemina which causes the insensitiveness of the iris to light during an attack; and remarks that, should the symptom turn out to be constant, it will give a valuable means of diagnosing the nature of the disease in an interval before seeing an attack.—*Med. Times and Gaz.*, Jan. 15, 1881.

Eye Symptoms in Locomotor Ataxy.

At a late meeting of the Ophthalmological Society of the United Kingdom Dr. J. HUGHLINGS JACKSON read an interesting paper on this subject. He first alluded to the great number of very different symptoms in this disease, better called tabes dorsalis, since the gait might be normal. He referred to the fact that some of the symptoms were occasionally found in other diseases. At present we have to study the symptoms as they occur in association or in sequence. In this paper three well-marked non-ocular tabetic symptoms were taken and considered in connection with certain ocular symptoms. Twenty-five cases in different stages furnished the material for the communication.

a. *Non-ocular symptoms.* (1) *The "Lightning" pains.*—There is a succession of sudden, small, severe short pains in batches. As Pierret and Buzzard have pointed out, these pains may occur about the head, although they occur mostly in the legs, trunk, and arms. Charcot and others have observed eruptions in the parts seized by pains. Buzzard has published the case of a patient (whom he permitted the author to see) who, with every batch of pains, has a small crop of herpes; this patient has double optic atrophy and Westphal's symptom (ab-

sence of so-called patellar tendon-reflex), as well as the pains; he walks well. An interesting feature in this case is that the patient had for several years crops of herpes before batches of pain, and then always both together. It is most important to note that pains are denied by some patients, who, nevertheless, have them. Many patients see no relation betwixt their pains and their amaurosis or ataxy, especially if the pains come years before. This one patient strenuously denied having any pains, but it came out, as it were accidentally, that he had had sciatica; really he had had true lightning pains. He had optic atrophy and Westphal's symptom. Many of those who deny pains will admit that they have long been subject to rheumatism or neuralgia, or to "flying gout," and will describe these things so that it is certain they are lightning pains. It is often difficult to get a patient to fix his mind upon his pains. A patient, aged fifty-four, had recently continuous severe pain in the toes and sides of his feet. This he admitted to be one of the symptoms of his disease, but ignored lightning pains, which he had, on and off, for twenty years; those pains were, he would have it, "only gout." It was difficult to get him to attend to questions about them. He had had incontinence of urine nine years; difficulty in walking, according to his account, six months according to his wife, slightly for about eighteen months earlier; his gait was only slightly ataxic. There was Westphal's symptom. The ocular symptom was that his pupils, which were small, did not contract to light.

It is to be insisted on that a patient may have for very many years the pains before any of the striking symptoms of tabes dorsalis. "I have recently seen a patient, about sixty years of age, who had pains which I concluded to be 'lightning' for about twenty years. His gait was normal; by most careful testing I could find nothing the matter with it. The patient had besides, of late years, attacks of what he called sickness, but really faintness, with intense depression for hours. That these were slight gastric crises I could not be sure; they possibly depend on derangement caused by very large quantities of opium he had taken for relief of pain. The narcotic taking was evidence of the severity of the pain; he began this practice many years ago. Hearing his account of pain, I looked for Westphal's symptom, and found it. He had an ocular symptom, too. The pupils did not contract at all to light, and, I thought, very sluggishly, during accommodation. I do not in the least doubt that this is a case of posterior sclerosis; Charcot and Bouchard report a case in which pain had been the only symptom; the necropsy showed commencing sclerosis of the posterior columns."

(2) *Westphal's symptom* ("absence of knee phenomenon," "loss of patellar tendon-reflex").—"Everybody knows that smart tapping just below the knee in healthy people makes the leg jump up. As Westphal and Erb point out, this does not occur in the great majority of cases of tabes. There is no doubt of the correctness of this statement. The jumping up upon the tapping is usually called patellar tendon-reflex, but as this name involves a theory much disputed and not accepted by the discoverer of the symptom, I will call the loss of this so-called reflex 'absence of the knee phenomenon,' or Westphal's symptom. It is by no means easy to be sure of the absence of the knee phenomenon. We should bare not the knees only, but the legs, let the trousers down, and take off tight drawers; then we should make the patient sit on the edge of a table with his legs hanging loose, and hit carefully both with the hand and a hammer. I am quite certain that the knee phenomenon is said to be absent when it is not. It is admitted that in cases which are evidently not cases of tabes, Westphal's symptom is present. Thus in atrophy of the quadriceps the knee phenomenon cannot, for obvious reasons, occur. Buzzard has published a case of diphtherial paralysis, in which there was Westphal's symptom. On the patient's recovery from the

paralysis the knee phenomenon returned. I have seen it absent in a case of diphtherial paralysis, but have not heard of the progress of the patient."

(3) *The ataxic gait.*—Under this head the author gave briefly the explanation of the gate of tabes dorsalis, which he gave in the *Lancet*, Jan. 30th, 1875, and the *Medical Times and Gazette*, July, 1873. He believes the so-called disorder of co-ordination to be a double condition—paresis of some movements and over-action of others. He illustrated by the duplex effects of paralysis of ocular muscles. A similar explanation has since been given by Pierret.

b. Three eye symptoms.—"One great question of interest is as to the frequency with which eye symptoms are the earliest symptoms. Since the Argyll Robertson's symptom does not inconvenience patients, it is hard to say whether it is ever first or not. I was never consulted for that symptom, although, as I shall mention shortly, I was once consulted for a condition somewhat like it. Excluding from consideration for the moment Argyll Robertson's symptom and Westphal's symptom, since we cannot learn anything of them from the patients' accounts, I found in nineteen cases that the earliest symptoms were as follows: in ten cases pains, in six double vision, in one abnormal gait, in one optic atrophy, in one mental symptoms; probably the last was a case of general paresis. The pains are often neglected in taking note of the earliest symptoms; manifestly this puts all wrong; makes the case seem to begin months or years later than it really does."

(1) *Paralysis of parts supplied by oculo-motor nerve trunks.*—Several cases were alluded to under this head. "A man aged sixty-three, who twelve months before had had paralysis of parts supplied by the left third nerve. I could find no symptom of tabes with one very important exception: this was Westphal's symptom. Not very long ago I should have had to say that he had no symptom of tabes. I could only have guessed tabes. Thanks to Westphal, I now feel sure that this patient is tabetic. It is important to say expressly that this patient's pupils acted well to light and during accommodation; he had no pains of any sort anywhere. He complained only of a heaviness in his head."

(2) *Alterations of pupils.*—The common condition described is what is called the Argyll Robertson pupil; the pupil does not act to light, and does not act during accommodation. This has been observed in tabes by Hempel, Vincent, Erb, Hutchinson, and others. It is a double condition, negative and positive, and in this way resembles the so-called disorder of co-ordination of locomotor movements. Erb calls the condition of inactivity of the pupil, "reflex pupillary immobility," and advances an hypothesis as to its fundamental community of character with Westphal's symptom. That hypothesis, however, had been previously made by Buzzard; he points out that both in Westphal's symptom and in the Argyll Robertson symptom there is loss of a reflex movement when the more voluntary movement is retained. Buzzard's hypothesis seems to harmonize with the explanation suggested as to the peculiarity of the gait. It must be remembered that we have not merely an affair of light and pupil. It is well known that brisk cutaneous irritations cause the pupil to enlarge; pinching a comatose man will often enlarge his pupils. Erb tells us that the pupils inactive to light in cases of tabes are not affected by such procedures; he says, too, that they are not affected during lightning pains. Frequently the tabetic pupil when inactive to light is myotic also. We have in all cases to consider the size as well as the immobility of the pupil; we must remember in this regard that the senile myotic pupil contracts to light. "Although much impressed by Buzzard's generalization already mentioned, I adopt no theory on the duplex condition of the pupil. I show a diagram copied from a paper by Erb (Seguin's *Archives of Medicine*, Oct. 1880) which gives that physician's view of the central conditions correspond-

ing to the double pupillary condition. The following case is, in my experience, a very rare one: A woman, aged twenty-six, was sent to me simply because her right pupil was larger than the left. It had been so three years. The right pupil was dilated, and absolutely motionless to light, and also during accommodation. Yet her ciliary accommodation on this side was perfect. This was severely tested by Mr. Couper. She could read No. 1 Jaeger from fourteen inches up to five, or by effort to four. The field was perfect. The fundus was normal, except that the veins were large, and convoluted at the disk, probably physiological; the media were clear. Her sight with this eye was perfect. The pupil of the left eye was most active, and of normal size; the left disk was slightly paler than the right; the veins as on the right; macula normal; doubtful slight limitation of nasal part of field. She could read Jaeger No. 2 with the left eye, but the centre syllable of a long word seemed blurred. This case puzzled me. She seemed to be in perfect health except for the ocular abnormalities mentioned. It occurred to me to test her knees. Neither I nor Mr. Couper found the smallest trace of the knee phenomenon. Several times did I re-examine into this, and pertinaciously inquire for other symptoms of tabes; there were no other symptoms of any kind. Except for the two things mentioned she is in seemingly perfect health." It is not said of Argyll Robertson's symptom that it is peculiar to tabes. It may be found in general paresis of alienists, at least reflex pupillary immobility, less frequently is there myosis, and the size of the pupils is more often unequal. Erb has found the pupillary condition in patients who had no other nervous symptoms, as well as in nervous affections which could neither be classed as tabes nor as general paresis. Again, it is not said that the action to light may not be present in very well marked cases of tabes. A man sixty-five had, as he was told by Pagenstecher, paralysis of the right external rectus in 1874; there was a return of double vision from some cause in 1876. He was subject to pains in his legs, his gait was ataxic; there was Westphal's symptom. He was obliged to carry a catheter to draw off his water. This patient's pupils do act to light. This was observed by Mr. Laidlaw Purves also, to whom the patient was sent for deafness. The following statement refers to cases from the pupil point of view. There were thirteen cases in which there was no optic atrophy. In ten of them the pupils did not act to light (in one case the pupil on but one side was inactive and was so in all ways). In nine of the ten cases of inactive pupils there was Westphal's symptom. Now as to paralysis of the oculo-motor nerves in the same thirteen cases. In one case with normal pupils and Westphal's symptom there had been paralysis of the third nerve. In one case of inactive pupils with Westphal's symptom there had been temporary double vision. In another case with inactive pupils and Westphal's symptom there was paralysis of one sixth nerve.

(3) *Optic atrophy.*—Tabes dorsalis is a disease which, like general paralysis, rarely occurs in women. "When clinical assistant at Moorfields, about twenty years ago, I was struck with the fact that many of the men who had 'white atrophy' of the optic disks had also pains in their legs—the pains were lightning pains. Later on, making a distinction as to the kind of atrophy, I concluded that the pains were a symptomatic link betwixt 'uncomplicated amaurosis' and locomotor ataxy. This relation had been previously noticed. In the *Medical Times and Gazette* of Sept. 1st, 1866, I wrote: 'We have (1) amaurosis without pains in the legs; (2) amaurosis with pains in the legs only; (3) amaurosis with pains in the legs and difficulty in co-ordinating the legs; (4) pains in the legs and difficulty in co-ordinating the legs, without amaurosis; (5) amaurosis without pains in the legs and with difficulty of co-ordination. I could now put five patients in a room showing the above sets of symptoms.' The term 'amauro-

sis' meant then atrophy which did not follow neuritis. I mention what I observed not with any view to priority, having none, but because what I then said, some fourteen years ago, was denied, and the authority of Duchenne, that the amaurosis in locomotor ataxy presented quite the ordinary features of atrophy of the optic nerve as it occurs from other causes, was quoted against me." The atrophy is now more particularly described as gray degeneration, and is supposed by Charcot and others to be parenchymatous. The peculiar limitation of the field of vision in cases of the atrophy in tabes is significant when we consider that the developed disease is in great part one of the locomotor system. The limitation would seem to correspond roughly to certain ocular deviations from cerebellar disease, in the way that hemiopia does to lateral deviation of the eyes from cerebral disease. In all cases of optic atrophy we should inquire for the pains, test the knees whether the gait be abnormal or not. The pains are often bridging symptoms, betwixt so-called uncomplicated amaurosis and tabes. Charcot says that so far back as 1868 he pointed out that the great majority of women admitted into La Saltpétrière for amaurosis have sooner or later manifestations of tabes. He mentions one case in which the amaurosis preceded the pains ten years. Gowers has seen a case of tabes in which optic atrophy preceded other ataxic symptoms twenty years. In the twenty-five cases mentioned there were twelve of optic atrophy. In two there were also ocular paralysis, and in one a history of it; in nine there was Westphal's symptom. In one of the three without this symptom there had been no pains; gait was slightly ataxic. In the second there had been double vision ten years ago; there is now paresis of the left third nerve; this patient had pains; his gait was normal. The third case was one of atrophy of one disk, with limitation of the field outwards and downwards; this patient saw green as gray, and red as reddish-brown; he had pains; his gait was good.

Dr. GOWERS stated that he had examined a number of cases of ataxy with myosis and loss of reflex action to light, and he could confirm Erb's statement that in this condition the pupils did not dilate on stimulation of the skin. He thought, however, that we must hesitate in regarding this phenomenon as strictly analogous to the loss of other reflex actions in the disease, which were due to a lesion of the sensory structures or reflex centres. It might be the result merely of the motor paralysis of the sympathetic fibres for the dilator pupillæ. This view was confirmed by one case which he had seen, in which, although there was loss of reflex action to light, there was not myosis, and the pupils did dilate on cutaneous stimulation.—*Lancet*, Dec. 18, 1880.

—

The Influence of Menstruation in the Progress of Pulmonary Consumption.

Dr. DAREMBERG, of Mentone, has been writing in the *Archives Générales de Médecine* upon this subject. There is no question that disturbances of the menstrual function very commonly accompany phthisis; and the view of their relationship to one another which is commonly accepted in this country, is that the latter is the cause, and the former the effect. Dr. Daremberg has seen reason for thinking that the state of the menstrual function has a distinct influence upon the lung-disease. His experience leads him to make the following statements upon this subject: Menstruation is sometimes a cause of phthisis; in the sense that women become phthisical who would not have done so had they been free from the monthly loss of blood. When phthisical changes have begun, the menstrual function may lead to attacks of congestion, either around old foci of disease, or in healthy parts of the lung, which may go on to hemorrhage or to inflammation. When the catamenial flow is suppressed, the ovarian molimen being still

present, these congestions are liable to become more intense and more dangerous. If the discharge should persist after ovulation has disappeared, it becomes simply a cause of anæmia, but does not provoke reflex congestions. When the two functions, uterine and ovarian, are suppressed—that is, when the menopause has completely taken place—menstrual congestions are no more to be dreaded. After delivery, similar pulmonary congestions of reflex origin are to be feared. The abrupt suppression of the menses cannot *per se* bring about tuberculosis; but it may cause its development in women predisposed to it. From these pathological generalizations he draws the following principles of treatment. In phthisical women the lungs should be carefully watched during the menstrual period, and at the least sign of mischief the nervous and vascular excitement should be calmed by the moderate use of digitalis; bromide of potassium, and quinine; absolute rest should be advised, and the pulmonary organs should be acted on by energetic revulsives (blisters, croton oil, etc.), and this during several successive periods. If the menstrual flow should cease while the ovarian molimen continues its course, the same treatment should be carried out, with the addition of external means to bring back the discharge (blisters, friction, hot baths, leeches to the lower extremities); and if these do not succeed, then the careful employment of purgatives and internal emmenagogues (general stimulants, such as alcohol and acetate of ammonia; local excitants, as rue, savin, aloes, uva ursi, apiol, ergot of rye, borax; and tonics, viz., strychnia and quinine). These measures, he holds, will do good, even if they should not re-establish menstruation. When the discharge persists after ovulation has ceased, we should with caution endeavour to diminish it, bearing in mind, that its sudden suppression may be dangerous; and the same remark applies to leucorrhœa. When both functions (uterine and ovarian) have disappeared, we should keep from seeking to re-excite the flow, for it will then be useless and cause anæmia. When, after a long absence, the menses reappear, without any great improvement being evident in the local and general condition, it is necessary to be very cautious about giving a favourable prognosis; for this apparent return of menstruation often indicates grave disturbance of the circulation, and is the precursor of serious mischief.—*Med. Times and Gazette*, Jan. 8, 1881.

The Muscles in Phthisis.

Two years ago FRÄNKEL, observing how many patients with phthisis presented hoarseness without any corresponding laryngoscopic changes, investigated the condition of the laryngeal muscles in order to ascertain whether any changes in them explained the symptom. In a considerable number of cases, both those in which there were ulcerations in the mucous membrane and those in which the naked-eye appearances were normal, he found constantly an atrophy of the striated muscles. The contractile substance was broken up, the striation indistinct, and a granular opacity had replaced the normal translucence, while in the fibres in which the process was more advanced there was an actual molecular destruction, and ultimate disappearance of the proper tissue. The connective tissue between the primitive bundles also presented a marked cell-formation, and the muscle nuclei were so increased in number as to constitute cellular sheaths to the fibres. This increase seemed to have produced additional damage to the muscular fibres, since these in places were apparently destroyed by the pressure of the groups of cells.

These observations have been confirmed by a series of investigations on forty phthisical subjects by Dr. POSADSKY of St. Petersburg, which show that the changes found by Fränkel in the muscles of the larynx exist also in other mus-

cles examined—viz., those of the upper and lower limbs, flexors and extensors, the intercostal muscles, and the diaphragm. The muscular fibres were pale, and exceedingly friable, so that they broke across with undue readiness, and could with difficulty be separated into longitudinal fibrils. This was found in two-thirds of the cases; in the remaining third the muscles were perfectly healthy. The microscope showed a granular degeneration of the fibres in all cases in which the naked-eye changes were observed. In many cases the transverse striation had entirely disappeared. Many of the fibres were strikingly narrowed, and some empty sarcolemma sheaths were seen. Fibres which were not degenerated also showed the tendency to break up into transverse segments which had been noted in the naked-eye examination. Why these changes should be so conspicuous in some cases of phthisis and absent in others it is difficult to say, since the cases with and those without the change presented nearly the same conditions and nearly the same visceral changes. The changes in the interstitial connective tissue described by Fränkel were not found by Posadsky.—*Lancet*, Jan. 22, 1881.

—

Passive Congestion of the Spleen.

At the suggestion of Virchow, the histological changes in the spleen which result from passive congestion have been studied very carefully by Dr. R. Nikolaides. In the indurated organ, the naked eye can detect a thick white layer around the vessels, which renders the tint of the section a paler red than might be expected. Under the microscope the walls of the bloodvessels, and especially those of the arteries, are seen to be enormously thickened by an increase of the adventitia and the adjacent zone of tissue, which passes gradually into the neighbouring reticulum of the splenic pulp. The trabeculæ are thickened, and the contiguous cells of the pulp undergo atrophy, just as do the outer cells of the acini of the liver in cirrhosis. These changes are more or less marked in all congested spleens, and confer upon the organ its increased density. Their degree appears to depend upon the slowness with which the mechanical congestion is developed. Besides these changes, alterations occur also in the intima of the vessels. They are most marked in the arteries, and are only found in the veins in very chronic cases. In the veins the change consists in merely fatty degeneration; but the inner coat of the arteries presents an overgrowth of all the connective tissue layers—a true end-arteritis, similar to that which Virchow has described in the veins of some other organs, as the lungs and liver, in passive congestion. It is difficult to say whether the muscular coat of the vessels is thickened or not; but Nikolaides believes that there is a considerable increase in the circular muscular fibres. Not only is this conclusion suggested by histological examination, but it is remarked that the mechanical congestion of the spleen never entails the degree of hyperæmia met with in other organs, as the liver and the kidney, in spite of the fact that the circulatory arrangement of the spleen is highly favourable to the occurrence of such hyperæmia. This fact is regarded as supporting the view that in congestion the muscular walls of the arteries contract, overgrow, and lessen the hyperæmia. The evidence on this point seems scarcely conclusive. Some share in this effect might be ascribed to an overaction of the muscular fibres proper to the splenic pulp, since it is difficult to understand, without such overaction, how the blood could be lessened in an organ, like the spleen, destitute of capillaries, by contraction of the arteries, if there exists an obstruction to the exit of blood. The splenic follicles, Nikolaides believes to take no part in the overgrowth of tissue which results from passive congestion.—*Lancet*, Jan. 29, 1881.

The Treatment of Abscess of the Liver.

In a recent communication (*Bulletin de l'Académie de Médecine*, No. 43, 1880), M. J. ROCHARD describes the treatment of hepatic abscess by free and direct incision, combined with the practice of Lister's antiseptic method. Three cases are reported, in which this treatment was carried out with complete success by Dr. STROMEYER LITTLE, of Shanghai.

Abscess of the liver, M. Rochard states, when not treated surgically, causes death in about 80 per cent. of the cases. The old methods of surgical treatment have not reduced this rate of mortality to any great extent; certainly, in cases of large abscess, to not less than 68 per cent. Consequently, surgeons have not been eager in interfering, and some, with Dr. Maclean, in consideration of the prolonged suppuration resulting from the opening of a large hepatic abscess, and of the putrefaction of pus and the gangrene consequent on the penetration of air into the large cavity, have declined to intervene. Most surgeons who have to deal with cases of this kind, think it right to open the abscess, but, before doing so, wait until œdema and redness of the abdominal wall have indicated the point to which the pus is making its way, and often whilst waiting lose their patient, or find that the abscess has burst internally. Finally, in cases where such practice is successful, the cure is attained at the price to the patient of many months of suffering and danger. A method which would permit the surgeon to act in good time, to operate with certainty, and to effect a cure within one month, must be regarded as constituting considerable progress. That such progress has been made seems, according to M. Rochard, to be proved by the results of the treatment carried out in the three recorded cases. Dr. Little had previously treated twenty cases of hepatic abscess either by frequently repeated puncture and aspiration, or by incision without any antiseptic precautions. All the patients died with the exception of one, in whom a small abscess with a chronic course projected into the epigastric region, and was opened there without any bad results. In his three recent cases, Dr. Little had recourse to the method described and discussed in M. Rochard's communication. This method consists in determining, with as much precision as possible, the seat of the purulent collection; in verifying the diagnosis by puncture and aspiration; then using the needle as a conductor, making a free incision into the abscess, clearing out all the contents, and, finally, preventing consecutive mischief by antiseptic injections, drainage, and Listerian dressings. The diagnosis of abscess of the liver, M. Rochard points out, is not easy. Local pain is not manifested until the pus has reached the surface of the organ, and perihepatitis has been excited. This symptom is often absent, even in cases of very large hepatic abscess. Reflex pain in the right shoulder, also, is very frequently absent. The only symptoms on which reliance can be placed, are increase in the size of the organ, digestive and respiratory disturbances, and fever. In most of the cases, the hepatitis succeeds dysentery or dysenteric diarrhœa. When, in a subject who has suffered from either of these affections, fever occurs, the digestion becomes disturbed, and the liver enlarges, it may be concluded that hepatitis has been developed. If the fever present a remittent character, with evening exacerbations, preceded by rigors and followed by sweating, the formation of an abscess should be expected, and steps at once taken to test this diagnosis by puncture and aspiration. The abscess is situated in the right lobe in seven out of ten cases, and in most cases projects at the convex surface of the organ. The dulness then extends towards the nipple, and is bounded by a curve with its convexity upwards. The patient is troubled by cough, dyspnœa, and pain during inspiration, and occasionally auscultation and

percussion reveal the signs of diaphragmatic pleurisy. In a case of this kind, the most favourable seat of an exploratory puncture would be the eighth or ninth intercostal space, in a line with the anterior border of the axilla. When the purulent collection projects at the concave surface of the liver, the false ribs are expanded, and the extent of the swelling may be made out by palpation. The spontaneous pains, when they occur, radiate towards the iliac fossæ and the sacral region. Vomiting is a frequent symptom. An exploratory puncture in such case is best made below the margin of the eighth rib, and at the point where there is tenderness on pressure.

The preliminary puncture is made by Dr. Little with a needle about three millimetres in diameter, the instrument having been dipped in carbolic oil, and the integument of the right hypochondrium washed with a 5 per cent. solution of carbolic acid. It is often found necessary to introduce the needle several times before pus can be obtained. These repeated punctures of the liver, as has been proved by the observations of Jaccoud and Lavigerie, are absolutely free from danger.

When the presence of pus has been made out, a free incision through the whole thickness of the abdominal wall is made by the side of the needle, and parallel to the ribs. The evacuation of the fluid contents of the abscess is facilitated by the introduction of forceps between the lips of the wound, and by expansion of the blades, and also by the transmission of manual pressure through the abdominal wall to the inferior surface of the liver. The cavity of the abscess is then washed out with a weak solution of carbolic acid, until no traces of pus, of flakes, and of portions of slough, can any longer be seen in the returning current of the injected fluid. A piece of drainage-tubing of very wide calibre is then passed to the bottom of the cavity, the outer portion of this being cut off on a level with the wound. Application is then made of the ordinary antiseptic dressing of gauze with protective and jaconette, which dressing is maintained by means of an elastic bandage. This dressing is changed daily, and at the same time the protruded portion of the drainage-tube is cut away. The results of this treatment in the three cases treated by Dr. Stromeyer Little were most satisfactory. The operation in each instance was immediately followed by improvement in the general condition of the patient. There was also immediate disappearance of fever, and complete absence, during the subsequent treatment, of any febrile reaction. In two cases, complete cure was attained within one month, and in the third case, in which a second operation was necessitated through relapse, the patient was able to travel on the seventy-sixth day.—*London Med. Record*, Jan. 15, 1881.

—

Jaundice in New-born Infants: Icterus Neonatorum.

There are many points of interest in the jaundice to which young infants are peculiarly liable. As age advances, they of course become liable to jaundice from exactly the same causes which produce it in adults. It occurs too, sometimes, as an epidemic, and would then seem to be dependent on some cause which might be either infection or one more or less widely spread and more or less uniformly acting within a given area. The etiology of the disease in new-born infants is difficult to study, owing to the nature of the circumstances; and thus at present we have hardly passed the stage of hypothesis on this point, although the disease is very common.

The latest summary of our present knowledge is from the pen of Dr. Alois Epstein; it is published in Volkmann's *Sammlung Klinischer Vorträge*. It would seem desirable to exclude from this consideration all cases of more or

less congenital jaundice, due to any malformations. Thus, obliteration of the larger ducts would offer an impediment to the flow of the bile; and this would lead to jaundice. Occasionally there is found an absence of the gall-bladder also, though this, except the ductus communis was also absent or closed, could never cause jaundice. Then, again, there may be congenital disease of the parenchyma (interstitial hepatitis), or occasionally cirrhosis, due to syphilis. Finally may be mentioned the pyæmic hepatitis, spreading along the umbilical vein, which, though rare, is nevertheless sometimes met with. With such cases we are not at present occupied, for there are anatomical grounds quite sufficient to account for the morbid condition.

Icterus neonatorum is *characterized* by an abnormal deposit of yellow pigment in the skin and mucous membranes. Many authors consider this jaundice as physiological and normal. They regard it as one of the transformation phases of the bright-red colour of the integument of new-born babies, which set in shortly after birth, and which they consider due to the altered temperature of the surrounding medium in which a child lives after intra-uterine life is over. It seems difficult, says our author, to accept such a theory, because so many children are born healthy and strong who yet never show a trace of this yellowness. Neither does the intensity of the colour stand in any constant relationship with the intensity of the previous redness; and further, children who are pale when born become jaundiced, while those of a deep red colour not infrequently change to a normal tint without evincing any yellowness at all. We must also remember that an erythema (redness) of several days' duration is itself very often a sign of impaired respiration and circulation. For these reasons we are bound to regard the icterus as a pathological condition.

The *frequency* with which jaundice is found will never be very accurately made out, owing to the difficulties of collecting the cases from private practice. But it would seem that the disease is much less common in the country and in private generally than among infants born in public lying-in institutions. This deduction is entirely found on the statement of mothers, who have already had children which were not jaundiced; but it must be counterbalanced by others, which go to prove without doubt that many exceptions to this rule occur. Dr. Charles West states, in his work on Children's Diseases (sixth edition), that jaundice seldom occurred in the Dublin Rotunda, while few children escaped it in the Paris Foundling Hospital. He believes that this was due to the excellent sanitary arrangements of the former, while those children which get into the Foundling Hospital in Paris have to contend largely with the ill effects of bad air as well as of cold. Seux, in Marseilles, found it present in 15 per cent. of the children; Scanzoni, in Würzburg, in 58 per cent.; Porak, in the Cochin Hospital in Paris, in 80 per cent.; and Kehrer, in Vienna, in 68.4 per cent.

The jaundice generally *comes on* during the first week of life, and in a majority of cases on the second or third day after birth; from this time, as age advances, the cases become rarer. It usually *lasts* from six to eight days, so that among children two weeks old it is rare to meet with any having a yellow skin. In premature children, in whom the physiological processes (the falling-off of the navel-string, the exfoliation of the epidermis, etc.) are somewhat retarded, so also the pathological take place less rapidly, and hence the jaundice may be protracted for two or three days longer. The *intensity* of the colour varies, among other things, with the complexion of the child, from a pale straw-yellow to a bright lemon or yelk-yellow. In cases the prognosis of which is bad, due to plugging of peripheral ducts, the yellow assumes a bluish or greenish tint—cyanosis icterica, in fact. The *distribution* of the pigment is not always uniform; thus the conjunctiva, though often yellow in colour, may be free, or not tinted to the same

extent as other tissues. The same also applies to the subcutaneous connective tissues. On the whole, it may be said that the yellowness depends chiefly on the amount of blood in a part, and on circulatory conditions of individual parts, and that the various shades which can be detected in new-born children would seem to be best explained by the transparency of the epidermis. At the approach of death, not infrequently the jaundice suddenly disappears from the integuments; and a conjunctiva which has shown palpable signs of icteric pigmentation during life, may be found quite free from it after death.

As regards *symptoms*, it will be best to emphasize those which do not occur in the jaundice of adult life. Pain in the region of the liver, and palpable enlargement of the organ, are not as a rule present, although the edge of the gland may just be felt if the abdominal walls are fairly flaccid. Slowing of the pulse is not present, nor is there any appreciable change in respiration. The function of the intestinal tract is normal; there is generally no constipation. On the other hand, any catarrh which may happen to be present cannot be attributed to the jaundice. The feces are always bile-stained, never, as in adults, clay-coloured, neither is there any obvious excess of fat present in them. The urine, even in intense forms of the disease, is often free from colour, and generally only light yellow; very rarely is it darkly stained as in adults, and when it is there are for the most part blood-corpuscles or blood-products to be found at the same time. Fairly often there is albumen in the urine, the presence of which, however, during the first few days of life does not seem to be very uncommon. It may also be mentioned that dark-coloured urine in children the subject of this complaint, on being tested, does not always contain bile-pigment; and even when it stains the linen yellow, it is not always to be put down to the presence of bile, as is too frequently done.

Epstein's method of obtaining the pigment is as follows: He collects the urine (with a catheter if necessary), and precipitates any albumen, if present; it is then shaken up with lime-water; the filtrate is washed in alcohol, and sulphuric acid added. The sediment thus produced consists of amorphous masses of uric acid together with the characteristic crystalline, or grains of, pigment. The pigment is easily distinguishable from the uric acid by its yellowish or yellowish-red colour. On adding caustic soda and acetic acid, the uric acid forms urate of soda, while the pigment remains unchanged. On microscopic examination, the pigment is found in the form of fine, tuft-like needles, or in tables, or sometimes as an amorphous deposit. It may likewise be found in the kidney-tubules and epithelium, and in the bloodvessels and interstitial connective tissue. Besides these places, this same pigment may be found more or less richly in the blood and in the other organs, chiefly in the neighbourhood of the vessels. Epstein has repeatedly found it in the brain, in circumscribed patches. It occurs also in the liver, but it is not found there more abundantly than in the places just mentioned. There is still some uncertainty as to the exact *nature and source* of this pigment in icteric children. Meckel and Neumann regard it as bilirubin, while Virchow and Buhl consider it as hæmatoidin; but, seeing that some chemists regard these two substances as almost identical, further research will be necessary before the point can be definitely settled.

The *etiology* of the condition is one of difficulty, and it must be by the way of exclusion rather than by direct means that we approach it. Most authors, if not all, and until quite lately, have not unnaturally associated it with changes in the liver, and regard it as hepatogenic—*i. e.*, as resulting from absorption of formed bile into the blood-circulation. Frerichs sought to explain it as a result of the altered blood-pressure in the liver which commenced at the moment of birth, when the navel-string was tied. But, though very clever, this is merely hypo-

thetical, for we are in complete darkness as to whether any alteration in the blood-pressure really does take place; if it were so, the condition at once becomes physiological, and it should be found, to a greater or lesser degree, in all children. Virchow, as long ago as 1846, pointed out the probable hæmatogenic origin, but a little later he withdrew from this opinion, and came to regard the jaundice as catarrhal and due to mechanical causes. Virchow's name secured for the catarrhal doctrine a wide acceptance. Epstein has bestowed special attention to the elucidation of this point, and has been unable to accept Virchow's teaching, for in most cases the ductus choledochus is found to contain bile along its whole length, the feces are bile-stained, and the liver, as regards size, colour, and consistence, is always normal. Other authors have sought for the source of this pigment in the integuments. Billard thought it due to congestion, and to the consequent transudation of blood-colouring matter. West also adopted this view. But, considering that the intensity of the jaundice, no less than its occurrence, seems to be quite independent of hemorrhages, such as occur after the use of forceps, or cephalhæmatoma, one is led to doubt this theory of mere congestion and transudation. On the other hand, there is much to confirm a hæmatogenic source from other causes than transudation—viz., an autochthonous formation of abnormal pigment resulting from the decomposition of fœtal red blood-corpuscles in the bloodvessels, and quite independent of the liver. The view is upheld by the well-known occurrence of jaundice in many of the acute infectious diseases and in hæmoglobinuria. Kühne has shown that the injection into the blood of a variety of substances (water, gallic acid, ether, ammonia) gives rise to the presence of bile-pigment in the urine. Gubler, in the year 1857, described a form of jaundice under the term "*ictère hémapheique*" in adults, resulting from a rapid destruction of red corpuscles. He distinguishes it from mechanical jaundice (*ictère bilipheique*) by its lighter colour, the absence of retardation of the pulse, and of itching in the skin. In the next place, are there any facts which confirm the occurrence of a destruction of blood-cells? Microscopic examination, as well as an enumeration of the blood-cells, largely confirm this view. According to Neumann and Kölliker, the blood of full-term infants contains a number of pigment granules, which after a while disappear; and further, there are observations which show that infants' blood is specifically heavier and richer in hæmatoidin than maternal blood. Spectral analysis also confirms this latter observation; while Hayem has shown that during the first fourteen days of life, and from day to day, the corpuscles present obvious and remarkable differences both in number and form. This being the case, we next inquire what should lead to such destruction of the red blood-cells. In answering the question, we naturally think of the altered conditions under which the child begins to live after intra-uterine life has ended, and of the important physiological changes by which this is brought about. Thus it seems probable that a large quantity of red corpuscles are called suddenly into use for respiratory purposes when the breathing medium is no longer the half-oxidized blood of the uterine sinuses, but the air directly inhaled into the lungs. Moreover, the blood corpuscles must be formed in a new way—not as in the fœtal state, from maternal fluids, but from the products of digestion. Thus it may be that the fœtal corpuscles may differ in certain respects from those of independent life. All things considered, then, this seems to be by far the most probable explanation of the occurrence of bile-pigment in the skin of young infants; it is favoured rather than otherwise by the fact that this so-called jaundice is most common in prematurely born infants and in those which are born weakly. Unfavourable hygienic circumstances will naturally react, and with proportionate power, on weakly children; and thus will be accounted for the large percentage of cases met with

in public institutions, which are chiefly for the use of the poor and needy, as compared with those placed in more favourable circumstances.—*Med. Times and Gaz.*, Dec. 4 and 18, 1880.

A Case of Acute Fibrinuria.

Dr. BAUMÜLLER (Virchow's *Archiv*, Band lxxxii. Heft 2) describes the case of a woman who, after several attacks of hæmaturia, extending over a period of three years, passed white slimy masses, and thereafter improved and recovered. On examining these masses, they were found to consist of casts of the calyces, pelvis, and ureter. Under the microscope the urinary deposit showed numerous pus-corpuscles, and many tiny crystals of triple phosphates, but no ephithelium. The coagula consisted of very fine granules in a homogeneous basis substance, with here and there disintegrating red blood-corpuscles. The granules disappeared on treatment with ether. The urine was clear yellow, turbid, neutral; specific gravity of 1014–15; it gave a precipitate on boiling and adding acid, which dissolved in excess. Further examination showed it to contain serum, albumen, and paraglobulin. The coagula were insoluble in water, alcohol, ether, chloroform, alkalies, and concentrated mineral and organic acids, both at ordinary temperatures and on boiling. In caustic potash, concentrated solution of sodium chloride (less in dilute hydrochloric acid), and concentrated acetic acid, there was some swelling to be observed; also after longer action of dilute hydrochloric acid, lime-water, solution of sodium chloride, acetic acid, and alcohol. In alcohol, after two or three days, the swollen masses broke up into ragged shreds. Attempts to digest the masses with gastric juice, obtained from a fistula in a dog, or with artificial gastric juice, failed. He considers the phenomena to have been due to an acute fibrinuria, such as Vogel has described (Virchow's *Handbuch der Specieller Path. und Therapie*, Band vi. 2 Abtheilung, sec. 542), and which is derived from a purulent catarrh of the pelvis of the kidney.—*London Med. Record*, Jan. 15, 1881.

Surgery.

The Catgut Ligature.

There is no part of the surgical practice instituted by Mr. Lister that has excited more interest and attention than his reintroduction of an animal ligature. In spite of many experiments, and much clinical experience, the opinion of the profession is far from unanimous in favour of carbolized catgut. Imperfections in its preparation, and its use in unsuitable cases, may explain a part, if not all, of the failures and accidents that have attended its employment, but its most ardent advocates, we believe, will grant that some improvement in its preparation is still demanded. A recent contribution to our knowledge of the action of catgut ligatures is found in a memoir entitled "Contribution à l'Étude de la Ligature dans le Traitement des Anévrismes," by Dr. G. F. Arnaud. Dr. ARNAUD ligatured the carotid or femoral artery of dogs fourteen times, using carbolized catgut, and examined the parts from four to sixteen days afterwards. In nine cases the ligature had entirely disappeared, or was only scarcely appreciable; in two it was partially absorbed, with destruction of the knot; and in three it was little altered. In one of the latter only four days had elapsed from the application of the ligature, which may be held to account for the fact; in the other two, examined on the ninth and sixteenth days respectively, there was an absence of

inflammatory reaction and clot, and the ligature was encysted, while for its absorption a rather abundant outpouring of lymph, or development of "granulations," is held to be necessary. In twelve of these cases the outer coat of the artery was found quite unaltered, not having been severed by the ligature; in two it was partially ulcerated, in neither case completely. In twelve cases, the inner and middle coats of the vessel were completely divided, as happens in the use of a silk or hempen thread; in one they were entire, and in one other it was doubtful whether they were partly divided or not. The clot, where not absorbed, was very small, and the obliteration of the artery was complete and firm. Senftleben has stated that internal clot rarely forms with catgut ligatures, but the evidence of these experiments, as well as of others, points to an opposite conclusion. Arnaud concludes that the effect of catgut on the artery is like that of hemp, except—a most important exception—that the outer coat is not ulcerated, the knot of the ligature softening before that occurs. It was noticed, in cases where a strand of catgut was left in the tract of the wound, that there was much more active cell-growth round the ligature than around these strands, with corresponding difference in the rate of absorption. The "absorption" of catgut is thus again fully corroborated, and still more the fact that the use of catgut ligatures is not necessarily followed by the complete severance of the artery, with the attendant risk of secondary hemorrhage, as always follows the use of hemp or silk.—*Lancet*, Jan. 22, 1881.

—

Gouty Cataract.

Dr. GALEZOWSKI (*Recueil d'Ophthalmologie*, Sept. 1880) records four cases of cataract recurring in gouty subjects. These cataracts belong to the secondary stage of gout; that, namely, in which all the tissues have become thoroughly saturated with the poison. While occupied in looking for glucose in diabetic cataracts, Dr. Galezowski accidentally found that in many cases uric acid salts were present in the crystalline lenses of gouty subjects. Gouty cataracts appear most usually from the ages of 50 to 70, and are generally hard, though he has also seen them in younger subjects of a more or less soft consistence. Gout often acts as the predisposing cause, after operation, of various inflammatory affections of the iris, sclerotic, and less frequently of the choroid. In the gouty diathesis, cataracts often become adherent, and are complicated with synechiæ and narrowing of the pupil. The best chance of success in these cases is to place the patient for some weeks before operation on a strictly anti-arthritic regimen, and to give large doses of salicylate of soda. In some of these cases, some days after operation, a collection of blood forms in the lower part of the anterior chamber; in others, it remains suspended in the aqueous humour, rendering it turbid. This blood transudes from the iris or ciliary circle, and is a very constant manifestation of the gouty diathesis. In some cases it would appear that the gouty manifestations in the eye were due to the irritation of the wound, and hence were, in their origin, traumatic. In such cases, local remedies are powerless, but the symptoms at once yield to large doses of salicylate of soda internally.—*London Med. Record*, Jan. 15, 1881.

—

Syphilis in Cataract.

Dr. GALEZOWSKI (*Recueil d'Ophthalmologie*, Sept. 1880) considers that syphilis may cause cataract in the adult primarily, or predispose to it hereditarily. He gives details of a case of kerato-irido-choroiditis in a child of four years of age affected with syphilis from its birth. In this case, a cataract became developed, and the eye was enucleated. The author has seen, in all, nine cases of congenital

cataract in children born of syphilitic parents. As regards the effects of syphilis in the adult, he has frequently seen cases of monocular cataract affecting an eye in which there was syphilitic choroiditis, while in the other eye the lens was perfectly transparent. He gives details of a case of syphilitic choroiditis attacking one eye, followed by the development of soft cataract six months afterwards in the other.—*London Med. Record*, Jan. 15, 1881.

Examination of Vision in Railway Employés.

The conclusions of the Committee, WARLOMONT and MOELLER, appointed by the Minister of Public Works in Belgium to report upon the vision of railway employés, with special reference to the detection of Daltonism, have recently been made public (*Annales d'Oculistique*, September–October, 1880). The committee recommends that in future all persons employed on the State Railways should, as regards their visual and chromatic acuity, be placed after examination in one of the following classes, viz., "very satisfactory," "satisfactory," and "unsatisfactory," the latter class being inadmissible into the public service. The requirements of the first class are laid down as follows: 1. Eyes and eyelids healthy, and free from all habitual irritation or congestion; 2. Normal acuity (= 1); refraction perfect within the dioptric; 3. A normal field of vision; 4. The power of distinguishing colours to the extent of $\frac{1}{2}$ at least; 5. Complete freedom from cataract or other disease. For the second class the conditions are the same, except that in one of the eyes visual acuity must be normal, in the other it may be $\frac{1}{2}$, and the perception of colour must in one be at least $\frac{2}{3}$, in the other at least $\frac{1}{2}$. In the report is included the instructions for the examining medical officer, which are as follows. Holmgren's colour-test is the one recommended, the candidate being required to match all the shades of several given colours selected at random. Refraction is to be tested by Loiseau's optometer, which is constructed on the principle of finding the reading distance of the patient when using a lens of known focal length. Visual acuity is to be determined by the use of a series of three test types prepared *ad hoc;* the limits of the field of vision by the movements of the hand, held at the distance of 1 metre.—*London Med. Record*, Jan. 15, 1881.

—

Treatment of Aural Polypi.

Although Professor POLITZER (*Wiener Medizin. Wochenschrift*, July 31, 1880) finds the action of alcohol, as recommended by Löwenberg, excellent in some cases of chronic otorrhœa, he considers that, in regard to the frequency of its good effect, it is inferior to boracic acid, as recommended by Bezold, whilst, in the rapidity of action, it ranks second to the caustic method of Schwartze. In the treatment of polypoid growths, however, the author strongly recommends its use in the form of rectified spirit. This is applied either pure or (if this produces much pain) diluted with an equal quantity of water, and is poured thrice daily, warm, into the meatus, being allowed to remain there from ten to fifteen minutes. The indications for its use are, he considers, as follows: 1. In the treatment of remains of polypi in the meatus, on the membrana tympani, or in the tympanic cavity, which are not removable by operation; 2. In cases of multiple granulations in the meatus, or on the membrana tympani; 3. In diffuse hypertrophy of the tympanic membrane; 4. In cases in which mechanical impediments in the meatus prevent the removal of polypi by instrumental means; 5. It may be employed experimentally in order to avoid an operation if possible in very nervous persons and in young children. The author relates a case in which, after partial removal of a polypus growing from the meatus, a portion of the size of a pea still remained; but, as the patient had to leave the town on business, alcohol

drops were prescribed. When he presented himself again after several months, the remains of the polypus had entirely disappeared. Other cases illustrative of the good effects of alcohol are also described. The author, it may be noted, expressly states that this treatment often requires to be continued for weeks or even months, and mentions that one of its chief advantages is that it can be employed with good effect by any surgeon, no especial skill in manipulation being required, as in the case of the application of strong caustics.—*London Med. Record*, Jan. 15, 1881.

Epithelioma of the Tongue.

A paper read by Prof. VERNEUIL at the Société de Chirurgie (*Bulletin*, November 10, *et seq.*), "On the Inutility and Danger of Pharmaceutical and Topical Treatment of Surgical Epithelioma," gave rise to a prolonged discussion. He observed that he addressed his observations not so much to the members of the Society as to practitioners at large, for while he did not believe that any of his colleagues had any faith in the medical treatment of epithelioma, unfortunately the great mass of practitioners are of a different opinion. He has scarcely ever seen a case that had not previously been treated by iodide of potassium, or even by mercury, while some caustic substance or chlorate of potash has always been used. "At the commencement of my practice, I also, on the faith of others, did what I now condemn." How comes it that a practice which is inefficacious and injurious has become so diffused and tenacious? 1. There is a very general belief that the iodide is a good means against neoplasms. It is, however, a great error to suppose that it is useful in true neoplasms; for, however useful it may be in tertiary syphilis, in scrofulous pseudo-plasms, or in chronic inflammations, it is of no avail in epithelioma or cancer. 2. The tongue is sometimes the seat of syphilitic manifestations, curable by mercury or the iodide, and as lingual syphilis is but ill known, and lingual epithelioma at its commencement still less known, the specific treatment is employed with the vague hope that the medicine will find out what it is suitable for. A cure may in this way be accidentally effected, but can be no rule why mercury should be given in all cases. The diagnosis is the great thing; and since the writings of H. Fournier the diagnosis of a tertiary glossitis is easy. There are, indeed, occasionally hybrid cases in which epithelioma occurs in a syphilitic subject, but this is of little consequence, as the prognosis and treatment of such a case is that of epithelioma. As in the immense majority of cases the diagnosis is easy, the practice of giving mercury or the iodide in epitheliomatous affections of the tongue should be abandoned. 3. Internal remedies are given to seem to be doing something, and not to alarm the patient by announcing the necessity of an operation, which also there may be inability to perform—it being also thought that there will always be time to seek the aid of a surgeon. This fear of alarming the patient about an operation decuples his danger, for this epithelioma, like all those which invade the mucous membranes, is a very dangerous one, although it may sometimes be cured when taken in time. Prof. Verneuil has met with four such cases, but then in these the epithelioma did not exceed the nail in size and was not deeply placed. But when more than a third of the tongue is invaded, when the floor of the mouth is seized, when the glands have degenerated, and the disease has lasted for more than a year, the case has become deplorably serious. The operation might have succeeded at the time when medicines were being given, but no chance of success remains at the late period when the surgeon is consulted. 4. The idea prevails that cauterization is useful for ulcerations, and these ulcers of the tongue are tormented by caustics, forgetting that

this method is useful only when destructive and not merely modificative. 5. When there is but little illusion as to the curative effect of medicines and cauterizations, it is still believed that these means are, at all events, innocent. This is a great error; not only is precious time lost, but the iodide of mercury and the chlorate may aggravate the conditions of the disease.

In the discussion which followed the paper, Dr. ANGER, in confirmation of Prof. Verneuil's views, stated that in a large number of 260 cases of cancer of the tongue which he had collected, he had found that the disease had been aggravated by the administration of the iodide, and especially by mercury. He did not think that the diagnosis was quite so easy as stated by Prof. Verneuil, and in doubtful cases a morsel of the tumour should be examined by the microscope. As a local treatment he had sometimes found interstitial injections of salicylic acid calm the pain, and especially the sympathetic pain of the ear. They even seem to arrest the progress of the disease. Dr. DESPRÈS also believed that Prof. Verneuil makes too light of the diagnosis, for among other affections of the tongue, psoriasis may be confounded with it. In doubtful cases he is in the habit of cauterizing gently with the nitrate of silver, and if after some days the ulceration undergoes a favourable modification, he feels certain that he has not to do with an epithelioma. When, after an operation, the case persists for ten years or more, we have had to do with a simple psoriasis, for epithelioma of the tongue always relapses within the space of two years. Prof. TRÉLAT observed that this communication of Prof. Verneuil's led to such useful and practical conclusions that he desired to adduce his own personal experience in support of it. In 1876, while drawing the attention of surgeons to the transformation of lingual psoriasis into epithelioma, he had insisted especially on the great advantage of operating early and on the efficacy of such operations. But patients and practitioners seem to do all they can to prevent these early and inoffensive operations, and only apply when the operation required has become extensive, and success nearly impossible. For the last five years Prof. Trélat has refused to perform these dangerous and useless operations. Of many patients who have consulted him when the epithelioma has been operable and success highly probable, he has never been able, by persuasion or alarms, to induce one to submit to it at that stage. The diagnosis should be made as early as possible, and in doubtful cases it is far better to perform an unnecessary operation than to leave the patient to the probability of an early death. All are agreed, in fact, as to the desirability of early operations, as must be the case when the results following these, as regards the prolongation of life, are contrasted with those which are observed in patients left to themselves. Prof. LE FORT, while agreeing that a cancroid which is limited should at once be operated upon, believes that when the disease has greatly extended, relapse takes place so rapidly that it is better to abstain from operating in these cases. Prof. Verneuil, however, differed from this view, believing that palliative operations which relieve the patient's sufferings, and may prolong his life for awhile, are justifiable. They must, however, be on a large scale, when they may give very great relief, and render life supportable for some months. M. GUYON expressed himself with more reserve as to these palliative operations—so rapid is the relapse in such cases. M. LABBÉ maintained that it was the right and duty of the surgeon to intervene even in these desperate cases, but he must intervene boldly, and proceed far beyond the disease itself, however far this may have reached. He ties the two linguals, and removes the part by means of large scissors, which enable him to effect this much more exactly than by any other means.

Prof. VERNEUIL afterwards drew the attention of his colleagues to the importance of extensive operations for epithelioma as a security against relapse, referring especially to the numerous cases of total extirpation of the tongue published

by Billroth and Schepffer. By means of extensive operations great success has sometimes been obtained in apparently very desperate cases. It might be thought that in far less formidable cases even more success would be obtained; but this is far from being so. The operations are too parsimonious, and a prompt relapse occurs, the relapse always occurring at one of three points—the stump of the tongue, the soft parts of the floor of the mouth, or in the cervical glands; and the rapid and inexorable relapse takes place because the operation has been incomplete. The glands in the vicinity of the epithelioma require to be removed; and since Röcher, of Bern, has removed even those that seemed unaffected, his operations have been much more successful than before.—*Med. Times and Gaz.*, Jan. 8, 1881.

—

Cases of Tracheotomy for Diphtheria in Children, Tumours of the Larynx, and Stenosis of the Larynx and Trachea.

Dr. KOERTE reports in the *Archiv für Klinische Chirurgie*, Band xxv. Heft 4, that no fewer than 149 tracheotomies for diphtheria (membranous croup) were performed in the Bethanien Hospital during the epidemic of diphtheria in Berlin in the year 1878. Of these, 34 recovered, and 115 died. In the latter months of the year the epidemic increased, not only in extent but in malignancy, so that against 56 tracheotomies with 30.3 per cent. recoveries in the first half of the year, there were 93 tracheotomies with only 18.2 per cent. recoveries in the second half of the year. The epidemic was at its height in October, November, and December; and of 62 children tracheotomized during that time, only 12 per cent. recovered. The patients were generally admitted at an advanced stage of the disease. In many, the diphtheritic affection had extended from the throat to the nasal passages; in such cases the prognosis was most unfavourable. Many cases were associated with measles, or with scarlet fever, and were then especially liable to terminate fatally. The greatest mortality occurred in children under 3 years of age. In the first year of life no operation was performed; but in the second year there were 29 cases with 3 recoveries, and in the third year, 27 cases also with 3 recoveries. The percentage of recoveries increased with the age and capacity of resistance of the children. Dr. Koerte regards croup and diphtheria as different degrees of the same affection; and considers that they cannot be distinguished clinically, although they present certain pathological differences, the nature of which, however, he does not state. With regard to the after-treatment, inhalations of weak solutions of lactic acid, when membranes were present in the trachea, of common salt or alum, when there was much muco-purulent secretion, were administered every two or three hours. Internally, chlorate of potash, wine, and camphor, were given. No remedies were applied locally to the throat, except when the mucous membrane was deeply affected. With the exception of cleansing the canula, and clearing the trachea of membranes by mopping it out with a feather, Dr. Koerte does not regard the after-treatment as having had any appreciable influence upon the course of the disease. The relief that is obtained by inhalations is to be attributed to the steam rather than to the medicaments. He thinks that the results, fatal or otherwise, depend entirely upon the severity of the epidemic, and not upon the treatment; as, during the year 1877, when the epidemic was much less severe, with 40 per cent. of recoveries, and during the first half of 1878, with 30 per cent. of recoveries, the treatment was the same as that pursued when the epidemic was at its height, during the second half of the year 1878, with only 18 per cent. of recoveries. Most of the deaths occurred within three days of the operation, the cause of death being in some cases collapse, but in the majority dyspnœa from the extension of

the membranes into the smaller bronchial tubes, for the clearing of which inhalations appeared quite inoperative; indeed, in these cases, little seemed to be gained from the performance of tracheotomy. [It does not appear, however, that the suction method, strongly recommended by Mr. Parker, for removing membranes from the bronchi, was resorted to.] The deaths that occurred more than three days after the operation, were generally due to broncho-pneumonia and infection of the wound. When the wound became infected, disinfectants, and occasionally cauterizations with chloride of zinc, were resorted to. In one case, albumen appeared in the urine, and suppuration of the shoulder-joint occurred. The patient recovered after the shoulder-joint had been opened antiseptically. In another case, diphtheria occurred for the second time. Tracheotomy was performed on each occasion, and the patient recovered. Three cases of papilloma of the glottis are reported. Case 1. A child, aged 8 years, had for a year suffered from hoarseness, and sometimes dyspnœa. The larynx was almost filled by papillary masses growing from the vocal cords. Three months later, the larynx was opened by dividing the cricoid cartilage, crico-thyroid membrane, and the lower portion of the thyroid cartilage in the middle line; the growths were then removed with the scissors and a sharp spoon, and their bases cauterized. Cicatrization of the wound was followed by a slight narrowing of the larynx. Four months after the operation, bougeal dilators were used and Dupuis' tube introduced. The tracheal canula was removed, and the wound allowed to heal. The patient was discharged with the voice hoarse. Both vocal cords were involved in the cicatrization; they were shortened and their movements much impaired. Case 2. A woman, aged 30, had, for six months, had difficulty in breathing. Tracheotomy was performed. The right vocal cord was found normal, but the left was almost covered by a tumour with a broad base, which nearly occluded the lumen of the glottis. An operation was not allowed, and the patient was discharged, wearing a canula. Case 3. A woman, aged 47, had often suffered from hoarseness, and for six weeks had had great difficulty in breathing. Beneath the vocal cords, papillary masses were perceived narrowing the lumen of the larynx. Tracheotomy was performed, and shortly afterwards the larynx was opened, the masses removed with the scissors and knife, and the actual cautery applied to the base of the growths. The wound in the larynx and in the thyroid cartilage cicatrized; but the patient could not dispense with the canula. Dr. Koerte remarks that these three cases belong to that class of tumours which, from having a broad base and penetrating deeply in the mucous membrane, can only be removed by opening the larynx and seizing them from the front. It is very easy to open the larynx when the trachea has been incised; an incision of part of the thyroid cartilage being sometimes sufficient to make the glottis entirely accessible. Two patients were treated for syphilitic stenosis of the larynx, and one for stenosis of the trachea following diphtheria. In one of these patients, in whom the vocal cords were completely destroyed and speech was lost, an artificial vocal apparatus in the form of a tube provided with a vibrating tongue, was introduced into the larynx by the mouth. By means of this the patient was able to speak, but it failed to be of any permanent use, in consequence of the metal tongue becoming clogged by particles of food, which could not be prevented on account of the loss of the epiglottis, from entering the tube. In the case in which tracheotomy was performed for diphtheria, stenosis of the trachea occurred, in consequence of ingrowing granulations immediately above the tracheotomy wound, so that on the cessation of the diphtheria the canula could not be dispensed with. The granulations were removed by scraping; and dilatation of the constriction with various curved bougies completely relieved the patient. The tracheotomy wound was then allowed to heal. The stenosis re-

curred in a month's time; tracheotomy was again performed, and the constriction successfully dilated as before. The wound again healed, but within a week or two asphyxia suddenly came on, the tracheotomy and dilatation were repeated a third time, and when the report was published, the patient was still under treatment.—*London Medical Record*, Jan. 15, 1881.

—

On Rapid Lithotrity.

In a paper entitled "On Lithotripsy and Poisoning by Chlorate of Potash," read before the Vienna Medical Society (published in full in the *Wiener Med. Wochenschrift*, 1880, Nos. 44 and 45), Prof. BILLROTH stated that he felt some embarrassment in bringing the subject before those who had had so much more experience in the operation than himself, inasmuch as it was not until the end of his fourteenth year of clinical practice that he had performed the operation at all. The results of his operations from 1867 until last year, when he adopted the new method, were as follows: Deducting two cases in which after the first sitting lithotomy was resorted to, there were 41 patients, for whom 120 sittings were required—these sittings, which at the commencement of his practice of the operation lasted from three to five minutes each, being soon afterwards extended to from ten to fifteen minutes. Of these 41 cases, 9 terminated fatally, or 7 per cent., reckoning each sitting as an operation. In 7 instances death followed on the first sitting, and in 2 on the second—resulting from periurethritis, pericystitis, diphtheria of the bladder, and pyæmia. The mean number of sittings for each stone was three and a half.

After adverting to the prolongation of the sitting which took place after the employment of anæsthetics became general, until at last Bigelow[1] astonished the world with his one-sitting operations, some of which lasted for three hours, Prof. Billroth states that he is able only to refer to six such cases in his own practice. These are of different import as regards judging of the feasibility of the method, in consequence of the very different size and hardness of the stones in the six cases. 1. In a man fifty-nine years of age, the operation lasted forty-three minutes, the stone consisting of uric acid and the urates, and measuring three centimetres in diameter. 2. A phosphatic stone in a patient aged forty-five measured two centimetres, the operation lasting twenty-three minutes. In the third and fourth cases, the stones, both of uric acid, were three and a half and four centimetres in diameter, the operations lasting fifty-five and one hundred and twenty minutes. The fifth case was that of a phosphatic calculus of two centimetres and a half, the operation lasting thirty minutes; and in the sixth case the operation lasted fifteen minutes, the calculus measuring one centimetre and a half. The diameters of the calculi are derived from measurements with the lithotrite, and it is not easy to judge of the size of the stone by means of the fragments that are discharged, it being generally much under-estimated. A tolerably near idea of its size may be attained by allowing all that is washed out of the bladder to pass through a calico filter—the fragments thus collected, pressed together, and compared with the diameter already obtained, furnishing an approximative representation of what the calculus must have been. But Prof. Billroth has often been struck with the small size of the stone as estimated by the fragments, giving rise at first to the belief that all these could not have come away. All the cases recovered, and in all the febrile reaction was insignificant. In the case which lasted two hours, shivering ensued, but this was only of a purely nervous character, such as frequently occurs in operations upon the bladder. Some of

[1] Am. Journ. Med. Sci., Jan. 1878.

the patients were dismissed cured in ten or twelve days. With respect to the possibility of fragments being left behind, all the cases four or five days after the operation have been carefully examined, and again this has been done three times with two days' interval, always with negative results. There can be no doubt that this operation is a great progress.

Prof. Billroth is convinced that, setting aside bad cases of cystitis and cystopyelitis, the unfavourable chances in all operations for stone do not arise from the danger of purulent inflammation or of hemorrhage from injury done to the mucous membrane, but from the large amount of ammonia, free or combined with carbonic acid, in the urine, and of the diphtheriticoseptic character of the inflammation of the bladder that is set up in such cases. So dangerous is this ammoniacal fermentation that is set up, that Prof. Billroth believes lithotrity in general, and especially lithotrity at a single sitting, is contra-indicated unless some means of counteracting its influence can be employed. The danger of the generation of ammonia in the structures, and especially in the bladder, has been long since shown in Prof. Billroth's own experiments, as also in those of the late Gustav Simon and Menzel. The question is, therefore, How is the formation of ammonia in the urine to be prevented? Prof. Billroth has found the alkaline condition of the urine in paralyzed persons capable of removal by repeated injections of muriatic acid; but as most patients object to the frequent introduction of the catheter for this purpose, he tried the daily administration of a drachm of phosphoric acid: and the urine can in this way be rendered acid; but after a few days such acidity of the stomach was produced that it had to be given up. The same may be said of muriatic and nitric acids. Under these means the urine was changed in appearance from intense yellow to the clearness of water, as if the acid had exerted an influence on the colouring matter. Patients who were suffering from cystitis and pyelitis found acids aggravate their suffering. In general, when the carbonate of ammonia disappears from the urine, the patient obtains great alleviation of suffering, the vomiting, fever, and penetrating smell of the urine disappearing, and the introduction of the catheter being much better borne. The chlorate of potash in a five per cent. solution, five grammes being taken in the course of the day, was next tried, and acted more promptly on the urine than did the acid. Prof. Billroth had hitherto believed that the statements which were published concerning its occasional poisonous effects had been exaggerated; for, when these related to diphtheritic children, he called to mind how many of such he had seen die from paralysis of the heart, without having taken any of the chlorate. He has, however, now met with a case in which he is convinced that death resulted from the use of this remedy. To a man aged sixty-four, who was admitted with urinary derangements of fifteen years' standing, the urine containing ammonia, much pus, and blood, the chlorate was ordered for three days in doses of five grammes (77½ grs.) per diem, the bladder being also washed out with diluted muriatic acid. The urine was acid on the second day, and on the third was clear, so that lithotrity, which lasted fifteen minutes, was then performed. After the operation the catheter had to be introduced several times, and the chlorate was continued. On the evening of the second day, when lying apparently asleep, he was found dead. At the autopsy the heart and large vessels were found filled with fluid blood of a very peculiar brown colour. This colour was quite remarkable; and Prof. Ludwig expressed the opinion that it was highly probable that the man died poisoned by the chlorate, although no trace of it was discoverable in the blood. After the death it was ascertained that fifteen instead of five grammes had been given daily, so that the patient had thus taken altogether from forty to forty-five grammes (620 to 700 grs.).

At the discussion which followed the reading of the paper (*Allg. Wien. Med.*

Zeit., Nos. 44 and 45), Prof. DITTEL, after referring to two cases in which Bigelow's operation was performed by Sir H. Thompson at Vienna, and eight others which he had operated upon himself, spoke highly in favour of the new procedure. The aspiration which was employed did not cause the hemorrhage of the bladder that was feared by some, while it enabled us to be assured whether there were still fragments in the bladder or not. This operation also in many cases may prevent the occurrence of a cystitis. A patient may have a stone in the bladder for years without excessive suffering; but no sooner is he lithotrized than several sharp-pointed fragments are suddenly produced, and cystitis is at once set up. But by this operation, in which the stone is completely crushed and removed at a sitting, he is preserved from this occurrence; while impactment of fragments in the urethra, which sometimes gives great trouble to the surgeon, and may even give rise to fatal results, is also avoided. So also for operations on the paralytic bladder, this is the only possible method. The number of cases has been as yet too small to allow of a final judgment being passed as to the amount of reaction produced, but, generally speaking, it has been not greater than under other modes of operating. Taken altogether, this new method can only be regarded as a very considerable progress.

With respect to the alkalescent condition of the urine, Dr. ULTZMANN observed that this may be caused either by fixed alkalies or by the carbonate of ammonia. In the former case, as often met with in diseases of the nervous system, it is secreted from the kidney in this alkaline condition; and here the internal administration of acids is of utility, especially carbonic acid, which transforms the amorphous and crystalline lime and magnesia salts of the urinary sediments into easily soluble bicarbonates. It is entirely otherwise when the alkalescence of the urine is brought about by the fermentation of the urea, an abnormal condition of the mucous membrane of the bladder, or the presence of micro-organisms. Here the change takes place in the bladder itself, the urine being secreted acid or normal in the kidney, and becoming alkalescent only in the bladder. When the urine has been for some time alkalized by carbonate of ammonia, we may be certain that the bladder itself or the parenchyma of the prostate has undergone change. It is in cases in which an incomplete discharge of the urine takes place that this ammoniacal condition of the urine occurs, and it is much more effectually treated by local applications than by the internal administration of acids. Prof. Dittel observed that in many cases of obstinate alkalescent urine in old vesical catarrh the bladder exhibits hundreds of diverticula, which resemble cavities of abscesses, with narrow orifices, and in such cases it is quite impossible to wash the bladder clean out so as to remove all the alkalescent urine. Prof. Drasche stated that as the result of numerous experiments he had found that two grammes of salicylic acid with glycerine and alcohol, or three grammes of salicylate of soda, may be given with advantage in vesical catarrh, these substances preventing the decomposition of the urine. They cannot, however, be given in these doses for a long time, and small doses are of no use; but they furnish a medicinal substances that proves efficacious for a time in affections of the bladder attended with rapid fermentation of the urine.

In reference to the influence of chlorate of potash taken internally, Dr. MARAZEK stated that when he was clinical assistant in the department for syphilis he had administered the chlorate in cases of cystitis and cysto-pyelitis arising from gonorrhœa. Altogether there were forty hospital and thirty out-patients who took daily five grammes, dissolved in 100 grammes of water with two drachms of cherry-laurel water added to it. Most of these persons took it for twelve to fourteen days, and several for a longer time, so that in most cases as many as sixty grammes were taken. Acid reaction commenced in the urine from

the second day, and the triple phosphate disappeared from the sediment, which became diminished in quantity and less viscid. The quantity of the urine remained the same, but the urgency for passing it was diminished. When it contained blood at the time the chlorate was given, the quantity of this was increased. No ill consequences resulted from the use of the chlorate, in spite of the fact that most of the patients were in a bad condition of health, and some of them the subjects of tubercle and syphilis. The chlorate must therefore be regarded as a valuable aid in treating this form of cystitis and cysto-pyelitis. Of the forty cases treated in hospital, twenty-eight completely recovered, and several others were much improved.

Dr. ENGLISCH observed that he had often administered the chlorate in affections of the bladder, and had found it useful in acute cystitis, but in chronic and obstinate cases it proved of no advantage. He gives from five to seven grammes daily during a month, and has never met with any ill consequence resulting from its use.

Prof. LUDWIG, referring to Prof. Billroth's fatal case of poisoning with chlorate of potash, stated that the blood, the contents of the stomach, and the urine were examined. The urine was turbid, with an acid reaction and very abundant sediment; it was albuminous, and contained a few blood corpuscles and granular cylinders. The blood had undergone great change, leaving the hæmatin free; but neither in it, in the contents of the stomach, nor in the urine, was any of the chlorate perceptible. This, therefore, had been completely reduced in the economy, and had passed into the condition of chloride of potassium—a remarkable circumstance, quite in contradiction to the views hitherto held by chemists. Binz was the first to show that organic substances (as yeast, blood, fibrin), when passing into a state of putrefaction, may decompose chlorate of potash; and it is now no longer doubtful that the chlorate, under certain circumstances, that we are at present ignorant of, may become wholly or in great part reduced within the body. As regards the mischievous influence of this, it would seem to be twofold. On the one hand, it operates like arsenic or phosphorus, the blood corpuscles being destroyed during the conversion of the chlorate into chloride of potassium. Secondly, it is decomposed into its base and acid by the weak acid urine in the kidneys, and the violent effects of the chloric acid have full play. The examples of strong acids being separated from their combinations by weaker acids are on the increase, so that it is not surprising that the weak acid urine is able to decompose the chlorate of potash.

Prof. HOFFMANN observed that as the effects of chlorate of potash on the blood can be demonstrated in a test-glass, it is only to be expected that the same changes would take place in the circulating blood.—*Med. Times and Gaz.*, Jan. 15, 1881.

On the Radical Cure of Varicocele.

At a meeting of the Royal Medical and Chirurgical Society (*Lancet*, Jan. 15, 1881), Mr. HENRY LEE read a paper on this subject, of which the following is an abstract.

The operation advocated in this paper is that of removing a portion of the anterior skin of the scrotum, and subsequently dividing the veins which are to be obliterated. All the steps of the operation are conducted through the wound made by the removal of the skin. The veins are compressed temporarily, so as to prevent hemorrhage, and then divided. The cut orifices of the veins are sealed with the black hot cautery, which if of proper temperature, is allowed to adhere to them for five or six seconds. The ligatures and needles used in compression are then removed, and the edges of the skin brought into apposition from below upward by carbolized sutures. Union by first intention takes place more

or less perfectly, and the patient is allowed to follow his usual avocations in three or four days.

Mr. PEARCE GOULD described an operation that he had performed for the radical cure of varicocele during the last two and a half years. It consisted in passing a loop of platinum wire round the spermatic veins subcutaneously, and then connecting it with a galvanic écraseur, and making it burn its way through the veins. In all he had performed it eleven times, two of the cases being incomplete, the other nine having resulted in cure without accident. The advantages he claimed for it were its safety, simplicity, painlessness, and efficiency, and the fact that the operation is limited to the diseased parts. He considered Mr. Lee's operation as more complicated, and held that the wound of the scrotum was liable to œdema, and even suppuration; and being closed by the continuous suture, there was no outlet for any effused serum. The removal of part of the scrotum has been shown to be ineffectual for the cure of varicocele, and he doubted if it were needful if the occlusion of the veins were satisfactorily secured. He thought it hardly safe to allow patients to get up and move about so soon as three or four days after such operations on veins, but preferred to wait until the clots were firmly adherent, and the divided ends of the vessels securely closed.

Mr. LEE, in reply, said, that, although he had now employed the actual cautery in a very large number of cases, he had never had a case of septic poisoning following its use. He attributed this to the complete closure of the veins—the small as well as the large—effected by it. It also effectually sealed the arteries; and if the operation is fairly done there is no oozing whatever. The wounds heal without any sloughing. His object in interfering with the scrotum was to prevent any return of the varicocele.

—

Case of Tying the Left Common Carotid Artery after Tonsillotomy.

In this case (*Hygeia*, Band xlii. April, 1880; Schmidt's *Jahrb.*, Band clxxxvii. No. 8, 1880) extirpation of the left tonsil had been performed by LIDÉN in the usual manner for excessive hypertrophy. The hemorrhage was not very great after the operation, but it did not cease after gargling with cold water, and became more and more abundant in spite of preventive means. After cauterization with lunar caustic, and application of perchloride of iron, it stopped for an hour, then recommenced, the clots becoming larger and more frequent. There was no arterial bleeding. Bladders of ice laid on the neck, and ice in the mouth, diminished the hemorrhage for a time; but afterwards it came on afresh and more violently. The patient's strength was failing, the pulse 130, weak and irregular. Three hours after the tonsillotomy, the common carotid artery was tied with carbolized silk, and immediately afterwards the bleeding from the mouth stopped. There was no pain felt on tying the carotid, nor pain in the head afterwards. Recovery was very slow, the patient not leaving her bed for three weeks. She had always been weak and chlorotic; and had always experienced strong pulsation of the left side of the neck, and very rapid action of the heart. There were no signs of hemophilia either in the patient or in her family. Dr. Lidén thinks that an abnormal ramification of the vessels was the cause of the bleeding. [A very simple method of arresting hemorrhage after excision of the tonsils, and one that does not seem so often resorted to as it deserves, is by pressure with a pad of lint on the end of a short stick.—*Rep.*]—*London Med. Record*, Jan. 15, 1881.

—

Dislocation of the Spine.

In the July number of the *Revue Mensuelle*, MM. A. POUSSON and F. LALESQUE give a detailed report of three cases of dislocation of the spine, observed

in the Saint André Hospital at Bordeaux; and to this report they attach an interesting review, with regard both to clinical and to physiological data, of the effects produced on the spinal cord through displacement of the bodies of the vertebræ. The first case, the subject of which was a male aged forty, was one of fracture of the laminæ of the eleventh dorsal vertebra with consecutive dislocation of this in front of the twelfth; contusion of the cord; ascending myelitis; and death on the eleventh day. In the second and third cases, the cervical portion was the seat of injury. One was an instance of partial dislocation of the fifth cervical vertebra, causing death on the third day, in a male aged twenty-four: and in the third case, which terminated fatally within thirty-six hours, there was luxation forwards of the fourth cervical vertebra and rupture of its inferior cartilaginous disk. The patient in the last case was a man aged thirty-eight.

These cases present no special point of interest with regard to the character of the injury. The chief value of the contribution is due to the very rigorous analysis of the pathological facts made by the authors, with the view of testing the results that have been attained by experimental physiologists as to the functions of the spinal cord. With the exception of acute pain at a fixed point of the spine, which was noted in all three cases, and of mobility of the eleventh dorsal spinous process in the first case, the local signs were very obscure. In the third case, there was not any appreciable distortion of the spine at the supposed seat of injury, and the movements of the neck were preserved. The lesion in each of the cases of injury to the cervical region was beyond the reach of a finger introduced into the pharynx. In severe injury to the spine and cord, the activity of the brain may be suspended for a time, as one of the results of the general disturbance known as shock. In two of the above cases there was temporary loss of consciousness, and in the third case an inability to articulate. In each of the three cases, there was motor paralysis in the region supplied with nerves by the segment of the cord below the seat of injury. In the first case, as the seat of injury was near the origin of the first pair of lumbar nerves, the parts supplied by the lumbar and sacral plexus were paralyzed, and voluntary motion of the lower extremities was abolished. In the other two cases, the brachial plexus had been cut off from the upper part of the cord, and therefore the upper extremities as well as the inferior were paralyzed. In the second case, the motor paralysis of the upper extremities was not complete, and the loss of movement affected only certain groups of muscles, in consequence, probably, of integrity of certain channels of conduction in the midst of the disorganized parts. There was, in the third case, complete and immediate paralysis of motion. This seems to be exceptional; for, according to Gurlt, in cases of dislocation below the third cervical vertebra, complete and immediate motor paralysis has rarely been observed.

In cases of injury to the spinal cord, the area of lost sensibility usually corresponds very closely to that of motor paralysis. This might be expected, from the fact that the anterior and posterior roots emerge from the cord at the same level. In the first case, there was anæsthesia of the lower extremities and of the abdominal wall as high as the umbilicus. In the second and third cases, the area on the trunk of anæsthesia was limited by a line drawn through both nipples. There was loss of sensibility in the upper limbs in the third case, but not in the second case. Here there was persistence of sensibility, which, together with freedom from motor paralysis in certain groups of muscles, indicated that there was but incomplete disorganization of the cord at the seat of injury. When all kinds of sensibility—to pain, touch, and temperature—are abolished, as was made out in the first and third cases, it may be concluded that the whole thickness of the spinal cord has been involved in the injury. Marked hyperæsthesia, with intense

pain just beyond the paralyzed region, was noted in the second and third cases. In the first case, there was exaggerated reflex motion in the lower extremities. The phenomena observed in the other two cases were not in accordance with the theory that, whenever a portion of the spine is cut off from the encephalon, the excito-motor power of this portion, provided it remain sound and intact, becomes intensified. In the second case, not the least movement of the lower extremities could be excited by active stimulation of the integument. In the third case, the extensor muscles of the lower limbs contracted when the soles were touched, but over all the other paralyzed parts the excito-motor action of the medullury exit remained indifferent to every kind of excitation. In these two cases, however, death occurred early and before the effects of shock had passed off. Besides, in each case the lower portion of the spine below the chief seat of injury was not quite sound, and hence the conditions of experimental physiology were not fulfilled. Contraction and immobility of the pupils were noticed in the second and third cases, in which the lesion of the cord existed at the lower part of the cervical region. Neither palpebral stenosis nor injection of the conjunctiva was observed in any of the cases.

The penis was found to be turgescent in all three cases, and in one case, the third, there was marked erection. Voluntary micturition was abolished in every case, and it was found necessary to relieve the bladder by catheterism. The urine remained normal as to quantity; and in one case only, the first, did the physical and chemical characters become altered. In the other two cases, however, death occurred very soon after the date of injury. Changes in the quality of urine, which take place in cases of injury to the spine, though they come on suddenly and progress with much rapidity, do not usually occur until after an interval of some days. In the above case the excretion became turbid and alkaline, and had an ammoniacal odour, for the first time, on the fourth day; on the fifth day it was purulent.

Tympanites was observed in all the cases, and was excessive in the second, so as to interfere with respiration. This condition is due, not only to paralysis of the muscular fibres of the intestine, but also to failure of contractility of the abdominal muscles, which then offer no effective resistance to gaseous distension of the intestinal canal. Intestinal paralysis is usually manifested also by absence of stools. Fecal incontinence, in cases of injury or disease of the spine, is to be regarded as a very unfavourable symptom. In the second case, involuntary discharge of fecal matter commenced a few hours before death.

In all the cases the breathing was diaphragmatic, and both the thorax and the abdominal wall moved but passively and under the influence of the play of the diaphragm. The seat of the injury to the spinal cord accorded perfectly, in the second and third cases, with the symptoms that were observed. The lesion existing at the level of the fourth and fifth cervical vertebræ paralyzed all the muscles of respiration save the diaphragm, supplied by the phrenic nerve emerging above the fourth cervical vertebra. In the first case, another reason must be found to explain the modification in the normal type of respiration; it is to be attributed, on the one hand, to paralysis of the abdominal muscles, and, on the other hand, to violent pain experienced by the patient in the right hypochondrium. In pleurodynia and pleurisy the patient, in order to obtain relief, instinctively keeps at rest the painful side of the chest.

In cases of serious injury of the spinal cord there is paralysis of the vaso-motor nerves, determining a diminution of the arterial pressure, and giving rise to certain modifications in the character of the pulse. These changes were observed in each of the cases reported by MM. Pousson and Lalesque, and in the second case

particularly remarkable changes in the pulse were made out on the second day, and when the effects of shock had passed off. It was noted that the radial pulse was strong, and that with each blood-wave there was a forcible impulse, but that at the same time the vessel was compressible. This impulse was still more marked in the larger arteries, as the femoral and the abdominal aorta. The sensation of a strong pulse is due to sudden variation of the arterial pressure in the vessel which is under the surgeon's finger. There is a feeble pressure in consequence of the vaso-motor paralysis, which, at the periphery, allows a ready flow of the blood from the arterial into the venous system; and this condition of feeble pressure passes suddenly into a condition of forcible pressure at the moment of the ventricular systole. The sphygmographic tracing presents, with pulse-modifications of this kind, a very high and vertically ascending line, and a concave and prolonged descending line. With regard to the number of cardiac beats, no deduction could be drawn from these cases. According to M. Marey, the movements of the heart in a given time are the more frequent, the less obstruction there is to overcome in the accomplishing of the ventricular systole. In these cases, therefore, as there was certainly diminution of the arterial pressure, and consequently a more ready flow of the blood-stream, an increase in the number of cardiac pulsations would have been expected. But in the first case only was there an acceleration of the pulse (112 to the minute): in the other two cases the pulse was 88 and 60. These facts, however, it is pointed out, do not really invalidate the law of Marey, since, in the second and third cases, the spinal lesion had involved the cervical enlargement and the region from which are derived the accelerator nerves of the heart. The authors failed to make out any precise results as to the temperature in these cases of spinal injury, in consequence of the disturbing influence of shock and consecutive inflammation. In conclusion, it is reported that, beyond some sloughing over the sacral region, in the first case, no indications of any trophic disturbance were observed.—*London Med. Record*, Jan. 15, 1881.

Midwifery and Gynæcology.

Cystic Degeneration of the Chorion with a Living Fœtus.

It has been maintained with much plausibility that cystic degeneration of the chorion results from the death of the embryo. A case, therefore, which completely negatives this view is both of interest and importance. Such a case has been put on record by Dr. C. Breus (*Wiener Medizinische Wochenschrift*, No. 36, 1880). It occurred in the private practice of Professor Braun. It was the patient's first pregnancy after ten years' marriage. Gestation went on without any unfavourable symptom until the fifth month, when metrorrhagia came on, so severe as to oblige the patient to keep her bed. A week afterwards labour-pains began. The uterus then reached to the umbilicus. The fœtal heart could not be made out, but fœtal movements were perceptible. The child and placenta were expelled naturally and easily. The child corresponded in development to five months' pregnancy; it weighed 440 grammes (1 lb. 1½ oz.), and lived for three hours. It presented no abnormality, and death appeared to take place simply from its having been prematurely born. The placenta and membranes weighed 320 grammes (10 oz.). The placenta showed in parts clusters of thin-walled vesicles of different sizes, the largest being as big as a hen's egg; at other parts it presented the general appearance of healthful placental tissue, but nevertheless, on close examination, vesicles of the size of a pin's head or a hemp-seed

could be seen in it. Microscopical examination showed, even in the least altered placental tufts, a pronounced increase of embryonic connective tissue with abundant intercellular substance. That this disease of the placenta did not lead to the death of the child, the author explains by supposing that it did not begin till later than usual, and that sufficient of the placenta was left in a tolerably healthy state to allow of the nutrition of the fœtus. He believes that had not the child been expelled prematurely, the progress of the disease must have led to its intra-uterine death.—*Med. Times and Gazette*, Dec. 25, 1880.

Induction of Abortion as a Therapeutic Measure.

The discussion of a paper by Dr. PRIESTLEY, on the Induction of Abortion as a Therapeutic Measure, at the last meeting of the Obstetrical Society of London, leads us to offer some remarks thereon. Dr. Priestley's paper was, of course, an ably written one. But it did not attempt to extend the boundaries of knowledge: it aimed rather at a temperate judicial summing-up of the conditions which may justify the artificial termination of pregnancy at an early stage. As to the soundness of the conclusions set forth, little doubt could have been felt. But no new facts were brought forward, either in the paper or in the debate. The *raison d'être* of the paper was, not that the author had any fresh information to communicate, but, to use his own words, because "the indications for the induction of abortion . . . had never been laid down with sufficient precision in this country." And the debate also was a somewhat barren one, the only speaker who recognized the wide bearings at issue being Dr. Barnes.

Dr. Priestley set forth seven sets of conditions in which he considered artificial abortion justifiable. In two of them the objection to it is what is called a "moral" one. These are (1) "pelvic deformity so great as to preclude the birth of a living child," and (2) "narrowing of the genital canal by tumours, cicatrices, or cancer, so as to prevent the passage of a viable child." The existence of these conditions is seldom found out until the end of the first pregnancy, when a dangerous operation is needed to effect delivery. Then, if the patient become pregnant again, the question presents itself, "Is it not right to empty her uterus before its burden has got too big to pass through the narrow strait which is its sole communication with the outer world?" The so-called "moral" objection is, that the woman knew what would be the natural result of a second pregnancy, and ought not to have incurred the possibility of it; she having done so, the medical man ought not to destroy a child to save her from the penalty to which she has voluntarily submitted herself. We agree entirely with Dr. Barnes in thinking this doctrine a barbarous one. "Who art thou that judgest another?" is the text we would commend to the consideration of those who hold that the turpitude of a poor deformed wife's offence in becoming pregnant after she is aware of her deformity, is only to be expiated by her running a risk of death considerably greater than if she had been condemned to capital punishment in the Old Bailey dock. In these cases the woman is not a free agent; and, as Dr. Barnes said, if pregnancy under such circumstances be really a crime calling for punishment at the hands of the medical man, there is a measure, at once penalty and preventive (which need not be mentioned), and which would fall with more justice upon the other side. The life of a healthy young wife and mother ought to outweigh in the balance that of any number of immature fœtuses.

In the second set of conditions the indications for artificial abortion stand upon different grounds. These include diseases which are believed to be so aggravated by the coexistence of pregnancy as to endanger life. Dr. Priestley specified (3)

obstinate vomiting of pregnancy; (4) eclampsia; (5) irreducible retroversion or retroflexion, endangering life; (6) hemorrhage; and a seventh class included the remainder.

The point which seemed to us too much overlooked, both in the paper and in the discussion (except by Dr. Barnes), was this: that it is not yet a question of this or that symptom, or collection of symptoms, calling for the termination of pregnancy. It is first and chiefly a question concerning the *natural history of disease*. We want to know what is the natural history of the vomiting of pregnancy, of eclampsia, etc., if the pregnancy be let alone; and then, what is the effect of abortion upon them. Till there is some certainty upon these points, nothing definite can be said upon the indications which denote, in each case, the necessity of abortion. Take, for instance, the vomiting of pregnancy. We know that it is usual for this to be troublesome during the first three or fourth months of pregnancy, and that then it generally gets better. But this typical course is widely departed from in particular instances, and we know hardly anything of the conditions which lead to such variations. But until we do, it is useless to dogmatize upon the effect of remedies. One speaker mentioned cases in which, after various modes of treatment had been tried without success, and abortion was thought necessary, the use of a favourite remedy of his own was followed by cessation of the sickness. We have little doubt that each man in the room could have also narrated cases in which his own pet drug had done good after others had failed. The explanation is, that probably in most such cases the vomiting would have ceased whether the medicine had been given or not; and the remedy which the patient happened to be taking, when the sickness naturally stopped, was given the credit of the cure. The induction of abortion has this advantage over all other remedies, that by it cure is certain. Sickness solely dependent upon pregnancy must cease when the pregnancy ceases. Dr. Priestley's cautious indications for abortion in these cases practically amounted to this: that if the patient be dying from incessant vomiting, abortion should be induced. We rather agree, however, with Dr. Barnes, that if it is to be done at all, it should be done earlier than this. But the point we want to insist on is this: that the indications for inducing abortion in cases of intractable vomiting of pregnancy cannot be formulated with any precision until the natural history of such vomiting is better known.

The induction of abortion in eclampsia does not stand upon such sure ground as in the case just mentioned; for it is not at all certain that in uræmic convulsions occurring in the early months of pregnancy, the evacuation of the uterus will benefit the patient. In retroversion of the gravid uterus there is the same uncertainty as to the need of abortion. There is no doubt not only that a retroverted pregnant uterus may right itself (and generally does, if the bladder be kept empty), but that even if it do not, pregnancy may go on as usual, and delivery be effected by the natural efforts. Dr. Priestley did not specify what are the cases in which retroversion of the gravid uterus may endanger life if abortion be not induced. We know that when these cases end fatally, it is usually through the bladder and kidney changes which are caused by the retention of urine—cystitis, pyelitis, rupture of bladder, sloughing of its mucous membrane, etc.—diseases which can be prevented by careful attention to the bladder, and which, when once set up, would probably not be much modified by the presence or absence of pregnancy. Dr. Priestley stated that he did not regard the mere fact that the displacement was irreducible as sufficient reason for inducing abortion. We may add, with reference to the cases that have been recorded in which the uterine contents were discharged by ulceration of its wall, that very competent critics have thrown doubt on the accuracy of the diagnosis in these

rare instances. The other indication which Dr. Priestley specified—viz., (6) hemorrhage—requires no comment.

The author's last group (7) was a very general one: "in certain other diseases where the complication of pregnancy is undoubtedly endangering life." Heart-disease, chorea, and insanity, were the conditions chiefly dwelt upon in the discussion. It is in these cases that our present contention applies with the greatest force. In the conditions named there are not yet materials for formulating the indications for artificial abortion. This question cannot possibly be settled until the more fundamental one has been elucidated: What is the effect of pregnancy upon the course of these diseases? It was Dr. Priestley's opinion that gestation has probably little influence on the progress of the malady; and therefore his practical advice was to "treat the morbid condition, and let the pregnancy take care of itself." Dr. Barnes took the opposite side, and went so far as to say that the disease depended upon the pregnancy. Whether in this statement he be correct or not, there can be no doubt that the point of view from which he treated the question is the only one which at present can help us to sound rules of practice. Little has been done, or rather little definite is known, as to the effect of pregnancy upon chorea or insanity. Cases have been recorded in which chorea or insanity coexisting with pregnancy ceased when the pregnancy was put a stop to; but others have been seen in which the artificial interference with gestation only made the patient worse. In heart-disease, thanks to the laborious and able work of Dr. Angus Macdonald, we are on surer ground; but even here much remains to be done.

We will conclude these remarks by repeating again the principle which we wish remembered in this connection; viz., that the question of the artificial induction of abortion for the relief or cure of morbid conditions of other parts is essentially one of the natural history of disease. We want to know more of the effect of pregnancy upon disease; and until we do, no scientific indications for the induction of abortion under such circumstances can exist.—*Med. Times and Gazette*, Jan. 8, 1881.

Treatment of Mammary Abscess.

Dr. HIRAM CORSON, of Conshohocken, Pa., strongly urges (*Am. Jour. Obstetrics*, Jan. 1881) the local use of ice in the treatment of mammary abscess. He puts the ice into a bladder with just enough water to form a water cushion that will adapt itself to the inflamed part.

Narrowness of the Uterine Orifices in relation to Dysmenorrhœa and Sterility.

In an interesting article on stenosis of the external os uteri (*Annales de Gynecologie*, Dec. 1880), Professor PAJOT relates three cases in which an extremely small os uteri was present, with the usual dysmenorrhœa and sterility in young married women. In all three cases the os uteri was gradually dilated by means of an ordinary uterine dilator. Pregnancy ensued in all three cases, although in the first case the os uteri was invisible to the naked eye, and almost invisible in the second case. Professor Pajot is opposed to incision of the external os uteri as a means of removing the stenosis, and prefers gradual dilatation. He draws the following conclusions. In the same way that any obstacle to the facile flow of menstrual blood may cause dysmenorrhœa, stenosis of the external orifice may cause it. When stenosis appears to be the cause, enlargement of the orifice is indispensable. The opening of the uterine orifices by cutting instruments exposes the patient to serious dangers—septicæmia, pelvic peritonitis, and metritis, and even to death. Sponge and laminaria tents also frequently lead to

serious complications, such as perimetritis and septicæmia. Dilatation, carried out by means of graduated dilators, for several minutes at each sitting, is, in the absence of proof to the contrary, absolutely free from danger. In cases of sterility depending on stenosis, it is only necessary to dilate the external os uteri; and where this has to be done, transverse dilatation appears to be more favourable to subsequent impregnation than circular dilatation.—*London Med. Record*, Jan. 15, 1881.

—

On the Operative Treatment of Cancer of the Cervix Complicating Pregnancy.

The above is the subject of a contribution in the *Zeitschrift für Geburtshülfe und Gynäkologie*, bd. v. s. 158, by Dr. RICHARD FROMMEL of Berlin. His observations are suggested by two cases of the complication, the histories of which are given at some length. The cases were severe, the affection having dated back to a period before conception in both. In the first, as natural delivery was plainly impossible, Cæsarean section was performed with antiseptic precautions. A deeply asphyxiated child was delivered, which, however, came round and lived for three months. The placenta and membranes, being adherent, had to be removed, and a drainage-tube was then introduced through the vagina and cervix. The uterine wound was closed by seven deep and several superficial silk sutures. The patient died in two days. On post-mortem examination it was found that the silk stitches had all come loose. The carcinoma was very extensive, affecting the cervix to the os internum, the parametria on the right side, the bladder and upper part of the vagina, and completely filling the entrance of the true pelvis. In addition there was hemorrhagic peritonitis, interstitial Bright, and commencing endocarditis. The second case came under treatment five days after the waters had come away. The child was then dead, and the presentation a cross one. That being so, an attempt was made to remove manually the degenerated tissue so as to open a channel for the extraction of the child. This was effected without injury to adjoining organs or any bleeding worthy of the name. A foot was pulled down, and the dead, slightly macerated, full-grown child delivered. After this there was only very slight bleeding; the placenta was removed by expression, and the uterus contracted fairly. The operation was well borne by the patient, and she continued tolerably well for a few days. She suffered greatly from pain, for which large doses of narcotics were administered, and lived for a fortnight, during which time rapid advance of the carcinoma was observed. No post-mortem could be obtained. The author then proceeds to discuss the question when and by what sort of operation carcinoma, when complicating pregnancy, ought to be dealt with. This he holds depends chiefly upon the degree of advance of disease. Provided the case be seen at a time when the whole diseased tissue can be removed, the author recommends this to be done irrespective of the stage of pregnancy or of the risk of abortion resulting. He maintains, however, that the latter is not likely. But if the extent of the disease is such as to render its complete removal impossible, Dr. Frommel recommends Cæsarean section with antiseptic precautions, in the interests of the child chiefly, provided the fœtus is alive and viable. But if the child be dead, he would follow the plan of treatment adopted in his second case. In discussing the question of diagnosis of early cancer, the author considers Spiegelberg's view in regard to the fixation of the mucous membrane to the subjacent tissues as doubtful, since Ruge and Veit have shown that carcinoma of the cervix has only seldom those ingrowths of epithelial tissue assumed by Spiegelberg to be present in all cases. He comes to the conclusion that accuracy of diagnosis can only be obtained by removing a small portion of diseased tissue and

subjecting it to microscopic examination. The operative interference for complete removal he recommends is the wedge-shaped excision of both lips of the os after Simon's method.—*Edinburgh Med. Journal*, Dec. 1880.

—

Cancer of the Uterus in the Seventeenth Year of Life.

That cancer of the uterus is exceedingly rare in early life every one knows. A few cases under the age of twenty have been recorded, but none in detail. Those that occur in old authors have, indeed, been rejected by later and more critical writers as instances of mistaken diagnosis; and a case of so rare a kind, mentioned without confirmatory details, must always be open to this suspicion. A case, therefore, that occurred in the clinique of Professor Späth, and is reported by Schauta in the *Wiener Medizinsche Wochenschrift* (Nos. 37 and 38, 1880), is of much interest. The patient was a weak and delicate girl, but no inherited tendency to carcinoma could be made out. She began to menstruate shortly after the completion of her fifteenth year, and the function was regularly performed without pain, but the flow was always abundant. In October, 1878 (the patient having completed her sixteenth year in December, 1877), a sanious watery discharge began to appear, accompanied with pain in the lower abdomen, so severe as to oblige her to keep her bed. In November an attack of profuse hemorrhage led her to seek medical advice. On examination, a rounded tumour, of the size of a walnut, uneven on the surface, was felt in the vagina. It seemed as if it grew from within the uterus; its pedicle passed through the os uteri. From its consistence, and from its being covered with adherent fibrin, it was at first suspected to be a placental polypus which had followed an early abortion. The uterus could not be made out to be enlarged, and the patient denied all possibility of a miscarriage. An attempt was made to remove the tumour with a Simon's sharp spoon; but the stalk was found too strong to admit this, and it was therefore cut away with curved scissors. It was found to grow from the right half of the vaginal portion of cervix; and on section and on microscopic examination was found to have the characters of malignant disease. The removal of the new growth was completed with a Sims's knife. The patient recovered, and remained well till January, 1879. Then some small nodules, at first of the size of millet-seeds, but subsequently getting larger, were discovered in the neighbourhood of the cicatrix. They were removed with the knife; but after this others appeared, which were destroyed with Paquelin's cautery. At the end of March a tumour as large as an egg was felt in the right parametrium. It was rounded, and not connected with the uterus. It grew so fast that at the end of April it reached to the umbilicus and filled both iliac regions. On May 12 bits of tissue microscopically shown to be malignant in character were discharged in the urine, proving that the bladder was now involved. On May 15 the patient died. The autopsy was made by Dr. Chiari. A mass as big as a man's head was found in the pelvis—the lower part of the ileum, the cæcum, lower part of ascending colon, and sigmoid being adherent to the mass. The uterus was small, and pushed to the left. The posterior wall of bladder and right vaginal fornix had been destroyed by the growth. Secondary growths were present in the lumbar lymphatic glands and in the lungs. The growth was very vascular, soft, grayish-red in colour, and exuding a milky juice on section. It was examined microscopically by Prof. Heschl. His report concerning the growth was, that it was a malignant adenoma; that no definite distinction could be drawn between a growth of this kind and a true cancer, and it must be looked upon as a transition form to the latter disease.—*Med. Times and Gazette*, Jan. 1, 1881.

MEDICAL NEWS.

Short-Sight in Relation to Education.

In an address recently delivered to the Birmingham Teachers' Association, Dr. Priestly Smith has given the results of the examination of the eyes of school children and college students, with reference to the existence and increase of myopia. 1636 pupils of the board schools and 357 students of the colleges in which young men and women are trained as teachers were examined. The ages of the former ranged from seven to thirteen, and of the latter from eighteen to twenty-three. Five per cent. of the school children were found to be short-sighted, and twenty per cent. of the college students. Though the number of the older subjects is not large enough to make the statistics at all conclusive as to the effect of education upon myopia, Dr. Smith's observations, so far as they go, confirm the results of previous more extended examinations. Ware, in a paper read before the Royal Society (London), seventy years ago, established the fact of the much greater prevalence of myopia among the educated classes than the uneducated. No precise observations based upon the careful examination of large numbers of eyes, however, were made until Cohn, of Breslau, in 1867, published the results of his now well-known researches.

The interest excited by these remarkable observations stimulated others to similar work, and many thousand examinations have been made, particularly of the eyes of school children, in this country as well as in Europe. The testimony of all the statistics thus collected, though varying in degree, is in the same direction, and shows a great excess of myopia among those who use their eyes in near work, and an alarming increase of the defect during school life. Dr. Siggel, among 1600 German soldiers, found that only 2 per cent. of those from the country were short-sighted, 4 per cent. of those who had been labourers in large towns, 9 per cent. of artisans, 44 per cent. of tradesmen, clerks, etc., and 58 to 65 per cent. of those who had been university students. Cohn examined the eyes of more than 10,000 school children, and found a constant progression in the percentage of myopia, as the classes advanced from year to year. The following are his figures.

Elementary schools	6.7 per cent.
Intermediate schools	10.3 "
High school	19.7 "
Colleges	26.2 "

In the high schools, 50 per cent. of the first class were found to be myopic, and 55.8 per cent. of the first class in the colleges. Erismann among 4358 school children in St. Petersburg found 10.2 per cent. of those under eight years of age, and 40 per cent. of those over twenty years of age myopic. No wonder, in the face of such startling revelations, that Dr. Loring, of New York, seriously discusses the question whether "the human eye is changing its form and becoming near-sighted under the influence of modern education," and that a recent French author exclaims in alarm that the whole civilized world is growing myopic.

Almost all the published statistics of school children have been obtained by the simultaneous examination of numbers of pupils in different stages of education, and nothing has yet been done on an extensive scale towards recording the history of individual cases. Indeed, this seems scarcely practicable unless by some systematized plan in connection with the public schools. Jaeger, years ago, recognized the importance of such records, and announced his intention of following the course of refraction in the same persons through their whole lives; for which purpose, Donders wished him "long life and faithful patients."

Dr. Hasket Derby is doing some good work in this direction at Amherst. He examined the Freshman class in 1875, with the intention of following at least four successive classes through their college course. This will test the truth of the general opinion, that there is comparatively little increase of myopia after twenty years of age, but can shed no light on the mode of its origin or the rate of its increase in the earlier stages. According to Javal, myopia rarely commences after eight or ten years of age, and, if this opinion is correct, its connection with the process of education might be somewhat complicated with the question of coincidence.

The literature of myopia has grown to be very voluminous, but, even in its more recent chapters, contains sufficient diversity of theories to show that many of the most important points connected with it are still far from settled. That its anatomical condition is a prolongation of the antero-posterior axis of the eyeball is almost the only point of universal consent; whether increased pressure or diminished resistance is the essential factor in producing this condition, and what may be the exact pathology of either, may, perhaps, be considered as open questions. Sclerotico-choroiditis posterior is generally abandoned as a prime cause, and the idealized plates with a convenient local bulging at the outer side of the optic nerve are no longer satisfying. Some authorities place their faith in hereditary weakness of the sclerotic, others assign to this cause a secondary role, and some are bold enough to discard it altogether, or even to set up race peculiarities in its place. Some charge the ciliary muscle with all the mischief and find hope only in atropia, while others accuse convergence and set the ciliary muscle to work with concave glasses. Perhaps, however, but few ophthalmic surgeons will refuse their consent to the following articles of

belief voted by the Ophthalmological Section of the International Medical Congress held at Geneva in 1877.

I. "The ordinary causes of myopia are heredity and eye work, the influence of which may be separate or combined.

II. "Hypermetropia may be transformed into true myopia, under the influence of near work, passing through emmetropia.

III. "The progress of civilization, and particularly of school education, tends to increase the extension of myopia.

IV. "The predisposition to myopia is often but not always hereditary. The influence of race upon this predisposition is still an open question.

V. "In use of the eyes for near work, three principal factors concur, with predisposed individuals, to produce the anatomical lesions of progressive myopia. These are, in the order of their importance, accommodation, convergence of the visual axes, and oculo-cephalic congestion.

VI. "The conditions of age, attitude, light, and duration, under which eye work is performed, as well as the character of the objects used, and the state of the visual apparatus itself, have a powerful influence in the development of myopia.

VII. "The prophylaxis of myopia requires a combination of individual, school, and domestic hygienic measures, in great part attainable by the co-operation of physicians, educational bodies, and the authorities. Among these measures should be included the use of convex glasses by hypermetropes."

—

Desiccated Ox-Blood and Hæmoglobine.—Dr. LE BON, in the *Journal de Thérapeutique* (November 25) protests against the claim which Dr. Andrew Smith and others in America have made of having invented this preparation, the full description of which he had published five years since in the *Comptes-Rendus* (1875), and notices of which were given in all the French medical journals. It has now, he states, been well tried at the Paris hospitals, and especially at the Children's Hospital, and has been found most efficacious in all cases in which re-constituents are required. It is indicated wherever iron, raw meat, or the phosphates are useful. Hæmoglobine, Dr. Le Bon says, is difficult to prepare, and in some modes of desiccation of blood all hæmoglobine is lost. He has had it prepared by a skilful chemist, and it is now in the trade. It is almost completely soluble in water, giving to this a magnificent red colour. It may be given in this way or with chocolate, or in the form of powder. The American plan of adding alcohol is chemically bad, as this precipitates the albumen. Dr. Le Bon observes that all the elixirs or wines sold containing any of the essential principles of blood or meat are an entire delusion, as they cannot contain an atom of the albuminoid principles which give to meat its nutritive properties.—*Med. Times and Gazette*, Dec. 4, 1880.

—

Guy's Hospital.—The *Lancet* (Dec. 25, 1880), in its summary of the events of medical interest during the past year, gives the following temperate but brief sketch of the recent troubles at Guy's Hospital which have during the past few months attracted a large share of professional attention in Great Britain.

"In the present year we have to mention with regret a disturbance of the harmony of one of our large endowed Metropolitan Hospitals, which threatens even yet to mar its historical usefulness and fame, and has already produced the resignation of its two senior medical officers, Dr. Habershon and Mr. Cooper

Forster. This discord began in an attempt on the part of the Treasurer and Governors to make fundamental changes in the nursing system of the hospital without previous consultation with the medical officers, who are as vitally interested in the efficiency and subordination of nurses and nursing as in the quality of the quinine or of the chloroform which they prescribe. As if to accentuate the scandal of a nursing system acting independently of the medical staff, two cases came to light which greatly shocked public feeling. One, that of a patient with chronic phthisis, who was subjected to a cold bath for an hour by one of the nurses, partly apparently with a penal view, and with a slight notion that it would do no harm therapeutically. Very shortly after symptoms of acute mischief in the head appeared, and soon proved fatal. The nurse was found guilty of manslaughter. In a later case a man was brought to the hospital after a fall, with a slight scalp wound. He was seen and the wound dressed *by a nurse slightly*. The next day he was brought back to the hospital and found to have fracture of the skull, of which he soon died. The controversy which took place between the Treasurer and the Governors, upholding the new nursing system on the one hand, and the medical men on the other, has occupied most of the year. On the part of the Treasurer and Governors it has been disrespectful and highly unmindful of what was due to the medical faculty of a hospital which has been made famous at home and abroad by its medical faculty. On the part of the medical staff there has been a want of decision, strength, and, we had almost said, self-respect; but it would be more proper to say respect for the profession they represent. Although, however, the senior medical officers have resigned, the public scandal remains of a great hospital so badly administered financially that it is deeply in debt, that nearly a hundred beds have had to be closed, and that by a system of self-election on the part of the Governors medical men have gradually been ousted from the Board of Management, and that the admission of two is now conceded as a sop to public and professional indignation. Clearly, we have not got to the end of the crisis at Guy's, which discredits the year 1880. But good will yet come out of it."

—

Rupture of the Vermiform Appendix.—The subject of this case was a robust soldier, forty-five years of age, who had been in good health until a week before, was brought into the hospital with the symptoms of peritonitis, and died two days afterwards. On examination, a large quantity of purulent fluid was found in the cavity of the abdomen, and the vermiform process, nearly five times its natural size, exhibited a large aperture, while its communication with the intestine was obstructed by a long bean-shaped concretion of a greenish colour. On cutting through this, there was found as its nucleus at the centre a piece of husk of rye, around which had formed deposits of phosphate and carbonate of lime, the calculus having attained a centimetre in diameter before it caused rupture of the process. The case differs from most of those on record in having caused rupture by distension, instead of by ulcerative process.—*Med. Times and Gaz.*, Jan. 8, 1881, from *Petersburg Med. Woch.*, 1880, No. 40.

—

Instantaneous Rigor Mortis.—Dr. J. EWING MEARS writes to us that "In a copy of the *London Times* of November 7, 1805, which has recently come into my possession, I find the following paragraph, forming a part of a description of the memorable naval engagement between the English and allied French and Spanish fleets off Cape Trafalgar:—

"'A man was so completely cut in two by a double-headed shot, that the whole of his body, with the exception of his legs up to his knees, was blown some yards into the water; but, strange to tell, his legs were left standing on the deck with all the firmness and animation of life.'

"As I do not know of any report of this remarkable case in surgical works, it has occurred to me that it would be well to record it at this time."

The retention in death of the last attitude of life as the result of instantaneous rigor, accompanying sudden and violent death, has attracted but little attention. A very interesting paper on the subject, illustrated by some remarkable cases observed in the War of the Rebellion, was published by Dr. John H. Brinton in the number of the *American Journal of the Medical Sciences* for January, 1870, p. 87.

—

Listerism in Japan.—Miss Isabella Bird, in her recent charming work, "Unbeaten Tracks in Japan," describes a visit to a native hospital at Kubota, under the charge of Dr. Kayobashi, who "is fresh from the medical college at Tôkiyô, and has introduced the antiseptic treatment with great success." Miss Bird says: "the odour of carbolic acid pervaded the whole hospital, and there were sprays enough to satisfy Mr. Lister! At the request of Dr. Kayobashi I saw the dressing of some very severe wounds carefully performed with carbolized gauze, under spray of carbolic acid, the fingers of the surgeon and the instruments used being all carefully bathed in the disinfectant."

—

Société Medico-Psychologique of Paris.—Dr. John P. Gray, of the Utica Asylum, has been elected an Associate Member of this Society.

—

An Ingenious Suggestion.—A French philanthropist proposes to diminish the mortality amongst the wounded in war by tattooing on the soldier's body the principal points where compression may be made in cases of hemorrhage. Life may be lost in a few minutes by a wound of a large artery, and it is thought that the soldier might often escape if he knew where to command an artery whilst waiting for help.

—

Ovariotomy during Pregnancy.—Karl Schroeder (*Zeitschrift für Geburtshülfe und Gynäkologie*), on the strength of seven successful ovariotomies during pregnancy performed by himself, and fourteen performed by Olshausen, with only two deaths, considers that ovariotomy, during pregnancy, is an operation not to be feared especially, and only to be avoided when especial contraindications are present. It improves the prognosis, he considers, for the mother, and probably does not injure it for the child. The operation is best performed during the earlier months of pregnancy; later, the broad ligaments are so full of dilated veins, that the treatment of the pedicle becomes more difficult and more dangerous.—*British Med. Journal*, Dec. 25, 1880.

—

Peritoneal Transfusion of Blood.—The transfusion of blood into the peritoneal cavity recommended by Ponfick, and supported by the experiments of Bizzozero and Golgi, has been recently practised in Italy with marked success. The case is reported in the *Annali di Ostetricia* of June last. The patient, who was moribund from hemorrhage after parturition, was transfused with 200 *grammes* of defibrinated blood taken from a man by venesection, and injected into the peritoneal cavity. There was no reaction; and the patient made an excellent recovery. The method is one which seems to deserve trial in this country.—*British Med. Journal*, Dec. 25, 1880.

—

Medical and Surgical History of the War.—A bill is now before Congress for the printing of fifty thousand copies of the four volumes which have been already

issued of the "Medical and Surgical History of the War of the Rebellion." Should the bill become a law, these books will be distributed gratuitously by Members of Congress, and consequently early application should be made by constituents desiring them.

—

The Introduction of Vaccination into America.—Dr. HENRY A. MARTIN, of Boston, gives in the *North Carolina Medical Journal*, for January of this year, a very interesting sketch, with fac-simile letters, of the efforts made by President Jefferson to extend the introduction of vaccination into this country at the beginning of the century.

—

International Medical Congress, London, 1881.—The following subjects, in addition to those previously announced, have been proposed for discussion:—

Section IV. (*Medicine*).—1. Localization of Disease in Brain and Spinal Cord, so far as pathognomonic and diagnostic; 2. Trophic Changes of Nerve-origin; 3. Vascular Changes, Functional and Organic, in Disease; 4. Primary Diseases of the Lymph-system; 5. Gout, Rheumatoid Arthritis, and Rheumatism; 6. Forms of Renal Disease (Bright's Disease); 7. Methods of Physical Diagnosis; 8. Therapeutic Methods: Revulsions, Blood-letting, Diet-cure, Uses of Heat and Cold, Drug-cure, etc.

Section I. (*Anatomy*) will receive communications relating to any of the following subjects: 1. Human Anatomy, descriptive, microscopic, and topographical; 2. Embryology and Teratology; 3. Anatomical Anthropology and Anthropometry; 4. Comparative Anatomy in so far as it illustrates structural changes in Man; 5. Improved Methods of Instruction in Anatomy, and of preparing and preserving Anatomical Specimens.

Section XI. (*Diseases of the Skin*).—1. The Relation between Constitutional Diseases and Diseases of the Skin; 2. The Nature and Treatment of Lupus Erythematosus; 3. The Influence of Climate, Difference of Race, and Mode of Living upon the Development and Character of Diseases of the Skin.

—

Louisiana State Medical Association.—The fourth annual meeting of this society will be held at New Orleans, on March 30, under the presidency of Dr. C. M. Smith, of St. Mary.

—

Statistics of Medical Journalism.—On the authority of M. DUREAU, one of the librarians of the Académie de Médecine, the present number of medical periodical publications for France and its colonies is 147, 95 of these being published in Paris, and 52 in the departments. The Germanic Confederation publishes 133 journals, Great Britain 69, Austria 54, Italy 51, Belgium 28, Spain 26, Russia 26, Holland 16, Switzerland 10, Sweden and Norway 9, Denmark 5, Portugal 4, the Danish Principalities 4, Turkey 2, Greece 1—the total for Europe being 583. In America there are 183 journals, in Asia 15, in Oceanica 4—the total for the various continents being 785. The number of medical journals created since 1679 exceeds 2500.—*Med. Times and Gazette*, Jan. 22, 1881, from *Lyon Médical*.

—

To Readers and Correspondents.—The editor will be happy to receive early intelligence of local events of general medical interest, or which it is desirable to bring to the notice of the profession. Local papers containing reports or news items should be marked.

HENRY C. LEA'S SON & CO.'S

(LATE HENRY C. LEA)

CLASSIFIED CATALOGUE

OF

MEDICAL AND SURGICAL PUBLICATIONS.

In asking the attention of the profession to the works advertised in the following pages, the publishers would state that no pains are spared to secure a continuance of the confidence earned for the publications of the house by their careful selection and accuracy and finish of execution.

The large number of inquiries received from the profession for a finer class of bindings than is usually placed on medical books has induced us to put certain of our standard publications in half Russia, and that the growing taste may be encouraged, the prices have been fixed at so small an advance over the cost of sheep, as to place it within the means of all to possess a library that shall have attractions as well for the eye as for the mind of the reading practitioner.

The printed prices are those at which books can generally be supplied by booksellers throughout the United States, who can readily procure for their customers any works not kept in stock. Where access to bookstores is not convenient, books will be sent by mail post-paid on receipt of the price, and as the limit of mailable weight has been removed, no difficulty will be experienced in obtaining through the post-office any work in this catalogue. No risks, however, are assumed either on the money or on the books, and no publications but our own are supplied, so that gentlemen will in most cases find it more convenient to deal with the nearest bookseller.

HENRY C. LEA'S SON & CO.

Nos. 706 and 708 SANSOM ST., PHILADELPHIA, March, 1881.

INCREASED INDUCEMENT FOR SUBSCRIBERS TO

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

TWO MEDICAL JOURNALS, containing nearly 2000 LARGE PAGES,

Free of Postage, for FIVE DOLLARS Per Annum.

TERMS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), with
THE MEDICAL NEWS AND ABSTRACT, monthly (768 pp. per annum), } Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance, Five Dollars.

THE MEDICAL NEWS AND ABSTRACT, free of postage, in advance, Two Dollars and a half.

*** Advance paying subscribers can obtain at the close of the year cloth covers, gilt-lettered, for each volume of the Journal (two annually), and of the News and Abstract (one annually), free by mail, by remitting ten cents for each cover.

It will thus be seen that for the moderate sum of FIVE DOLLARS in advance, the subscriber will receive, free of postage, the equivalent of four large octavo volumes, stored with the choicest matter, original and selected, that can be furnished by the medical literature of both hemispheres. Thus taken together, the "JOURNAL" and the "NEWS AND ABSTRACT" combine the advantages of the elaborate preparation that can be devoted to the Quarterly with the prompt conveyance of intelligence by the Monthly; while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable when periodicals from different sources are taken together.

The periodicals thus offered at this unprecedented rate are universally known for

their high professional standing.

I.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES,

EDITED BY I. MINIS HAYS, M.D.,

for more than half a century has maintained its position in the front rank of the medical literature of the world. Cordially supported by the profession of America, it circulates wherever the language is read, and is universally regarded as the national exponent of American medicine—a position to which it is entitled by the distinguished names from every section of the Union which are to be found among its collaborators.* It is issued quarterly, in January, April, July, and October, each number containing about three hundred octavo pages, appropriately illustrated wherever necessary. A large portion of this space is devoted to Original Communications, embracing papers from the most eminent members of the profession throughout the country.

Following this is the REVIEW DEPARTMENT, containing extended reviews by competent writers of prominent new works and topics of the day, together with numerous elaborate Analytical and Bibliographical Notices, giving a fairly complete survey of medical literature.

Then follows the QUARTERLY SUMMARY OF IMPROVEMENTS AND DISCOVERIES IN THE MEDICAL SCIENCES, classified and arranged under different heads, and furnishing a digest of medical progress, abroad and at home.

Thus during the year 1880 the "JOURNAL" contained 67 Original Communications, mostly elaborate in character, 170 Reviews and Bibliographical Notices, and 147 articles in the Quarterly Summaries, illustrated with 47 wood engravings.

That the efforts thus made to maintain the high reputation of the "JOURNAL" are successful, is shown by the position accorded to it in both America and Europe as the leading organ of medical progress:—

This is universally acknowledged as the leading American Journal, and has been conducted by Dr. Hays alone until 1869, when his son was associated with him We quite agree with the critic, that this journal is second to none in the language, and cheerfully accord to it the first place, for nowhere shall we find more able and more impartial criticism, and nowhere such a repertory of able original articles. Indeed, now that the "British and Foreign Medico-Chirurgical Review" has terminated its career, the American Journal stands without a rival.—*London Med. Times and Gazette*, Nov. 24, 1877.

The best medical journal on the continent.—*Boston Med. and Surg. Journal*, April, 1879.

The present number of the American Journal is an exceedingly good one, and gives every promise of maintaining the well-earned reputation of the review. Our venerable contemporary has our best wishes, and we can only express the hope that it may continue its work with as much vigor and excellence for the next fifty years as it has exhibited in the past.—*London Lancet*, Nov. 24, 1877.

The Philadelphia Medical and Physical Journal issued its first number in 1820, and, after a brilliant career, was succeeded in 1827 by the American Journal of the Medical Sciences, a periodical of world-wide reputation; the ablest and one of the oldest periodicals in the world—a journal which has an unsullied record.—*Gross's History of American Med. Literature* 1876.

The best medical journal ever published in Europe or America.—*Va. Med. Monthly*, May, 1879.

It is universally acknowledged to be the leading American medical journal, and, in our opinion, is second to none in the language.—*Boston Med. and Surg. Journal*, Oct. 1877.

This is the medical journal of our country to which the American physician abroad will point with the greatest satisfaction, as reflecting the state of medical culture in his country. For a great many years it has been the medium through which our ablest writers have made known their discoveries and observations.—*Address of L. P. Yandell, M.D., before International Med. Congress*, Sept. 1876.

And that it was specifically included in the award of a medal of merit to the Publishers in the Vienna Exhibition in 1873.

The subscription price of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" has never been raised during its long career. It is still FIVE DOLLARS per annum; and when paid for in advance, the subscriber receives in addition the "MEDICAL NEWS AND ABSTRACT," making in all nearly 2000 large octavo pages per annum, free of postage.

II.

THE MEDICAL NEWS AND ABSTRACT.

Thirty-eight years ago the "MEDICAL NEWS" was commenced as a monthly to convey to the subscribers of the "AMERICAN JOURNAL" the clinical instruction and

* Communications are invited from gentlemen in all parts of the country. Articles inserted by the Editor are liberally paid for by the publishers.

current information which could not be accommodated in the Quarterly. It consisted of sixteen pages of such matter, together with sixteen more known as the Library Department and devoted to the publishing of books. With the increased progress of science, however, this was found insufficient, and some years since another periodical, known as the "MONTHLY ABSTRACT," was started, and was furnished at a moderate price to subscribers to the "AMERICAN JOURNAL." These two monthlies have been consolidated, under the title of "THE MEDICAL NEWS AND ABSTRACT," and are furnished *free of charge* in connection with the "AMERICAN JOURNAL."

The "NEWS AND ABSTRACT" consists of 64 pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, by gentlemen of the highest reputation throughout the United States, together with a choice selection of foreign Lectures and Hospital Notes and Gleanings. Then follows the MONTHLY ABSTRACT, systematically arranged and classified, and presenting five or six hundred articles yearly; and each number concludes with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

As stated above, the subscription price to the "NEWS AND ABSTRACT" is Two Dollars and a Half per annum, invariably in advance, at which rate it ranks as one of the cheapest medical periodicals in the country. But it is also furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

In this effort to furnish so large an amount of practical information at a price so unprecedentedly low, and thus place it within the reach of every member of the profession, the publishers confidently anticipate the friendly aid of all who feel an interest in the dissemination of sound medical literature. They trust, especially, that the subscribers to the "AMERICAN MEDICAL JOURNAL," will call the attention of their acquaintances to the advantages thus offered, and that they will be sustained in the endeavor to permanently establish medical periodical literature on a footing of cheapness never heretofore attempted.

PREMIUM FOR OBTAINING NEW SUBSCRIBERS TO THE "JOURNAL."

Any gentleman who will remit the amount for two subscriptions for 1881, one of which at least must be for a *new subscriber*, will receive as a PREMIUM, free by mail, a copy of any one of the following recent works:—

"SEILER ON THE THROAT" (see p. 19),
"BARNES'S MANUAL OF MIDWIFERY" (see p. 25),
"TILBURY FOX'S EPITOME OF DISEASES OF THE SKIN," new edition (see p. 18),
"HOLDEN'S LANDMARKS, MEDICAL AND SURGICAL" (see p. 6),
"BROWNE ON THE USE OF THE OPHTHALMOSCOPE" (see p. 29),
"FLINT'S ESSAYS ON CONSERVATIVE MEDICINE" (see p. 15),
"STURGES'S CLINICAL MEDICINE" (see p. 15),
"SWAYNE'S OBSTETRIC APHORISMS," new edition (see p. 21),
"TANNER'S CLINICAL MANUAL" (see p. 5),
"WEST ON NERVOUS DISORDERS OF CHILDREN" (see p. 20).

*** Gentlemen desiring to avail themselves of the advantages thus offered will do well to forward their subscriptions at an early day, in order to insure the receipt of complete sets for the year 1881.

☞ The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" may be made at the risk of the publishers, by forwarding in REGISTERED letters. Address,

HENRY C. LEA'S SON & CO., Nos. 706 and 708 Sansom St., Phila., Pa.

DUNGLISON (*ROBLEY*), *M.D.*,

Late Professor of Institutes of Medicine in Jefferson Medical College, Philadelphia.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE: Containing a concise explanation of the various Subjects and Terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence, and Dentistry. Notices of Climate and of Mineral Waters; Formulæ for Officinal, Empirical, and Dietetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonymes; so as to constitute a French as well as English Medical Lexicon. A New Edition. Thoroughly Revised, and very greatly Modified and Augmented. By RICHARD J. DUNGLISON, M.D. In one very large and handsome royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, $7 50; half Russia, $8. (*Just Issued.*)

The object of the author from the outset has not been to make the work a mere lexicon or dictionary of terms, but to afford, under each, a condensed view of its various medical relations, and thus to render the work an epitome of the existing condition of medical science. Starting with this view, the immense demand which has existed for the work has enabled him, in repeated revisions, to augment its completeness and usefulness, until at length it has attained the position of a recognized and standard authority wherever the language is spoken.

Special pains have been taken in the preparation of the present edition to maintain this enviable reputation. During the ten years which have elapsed since the last revision, the additions to the nomenclature of the medical sciences have been greater than perhaps in any similar period of the past, and up to the time of his death the author labored assiduously to incorporate everything requiring the attention of the student or practitioner. Since then, the editor has been equally industrious, so that the additions to the vocabulary are more numerous than in any previous revision. Especial attention has been bestowed on the accentuation, which will be found marked on every word. The typographical arrangement has been much improved, rendering reference much more easy, and every care has been taken with the mechanical execution. The work has been printed on new type, small but exceedingly clear, with an enlarged page, so that the additions have been incorporated with an increase of but little over a hundred pages, and the volume now contains the matter of at least four ordinary octavos.

A book well known to our readers, and of which every American ought to be proud. When the learned author of the work passed away, probably all of us feared lest the book should not maintain its place in the advancing science whose terms it defines. Fortunately, Dr. Richard J. Dunglison, having assisted his father in the revision of several editions of the work, and having been, therefore, trained in the methods and imbued with the spirit of the book, has been able to edit it, not in the patchwork manner so dear to the heart of book editors, so repulsive to the taste of intelligent book readers, but to edit it as a work of the kind should be edited—to carry it on steadily, without jar or interruption, along the grooves of thought it has travelled during its lifetime. To show the magnitude of the task which Dr. Dunglison has assumed and carried through, it is only necessary to state that more than six thousand new subjects have been added in the present edition.—*Phila. Med. Times*, Jan 3, 1874.

About the first book purchased by the medical student is the Medical Dictionary. The lexicon explanatory of technical terms is simply a *sine qua non*. In a science so extensive, and with such collaterals as medicine, it is as much a necessity also to the practising physician. To meet the wants of students and most physicians, the dictionary must be condensed while comprehensive, and practical while perspicacious. It was because Dunglison's met these indications that it became at once the dictionary of general use wherever medicine was studied in the English language. In no former revision have the alterations and additions been so great. More than six thousand new subjects and terms have been added. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference. We may safely confirm the hope ventured by the editor "that the work, which possesses for him a filial as well as an individual interest, will be found worthy a continuance of the position so long accorded to it as a standard authority."—*Cincinnati Clinic*, Jan 10, 1874.

It has the rare merit that it certainly has no rival in the English language for accuracy and extent of references.—*London Medical Gazette*.

As a standard work of reference, as one of the best, if not the very best, medical dictionary in the English language, Dunglison's work has been well known for about forty years, and needs no words of praise on our part to recommend it to the members of the medical, and, likewise, of the pharmaceutical profession. The latter especially are in need of such a work, which gives ready and reliable information on thousands of subjects and terms which they are liable to encounter in pursuing their daily avocations, but with which they cannot be expected to be familiar. The work before us fully supplies this want.—*Am. Journ of Pharm.*, Feb. 1874.

A valuable dictionary of the terms employed in medicine and the allied sciences, and of the definitions of the subjects treated under each head. It reflects great credit on its able American author, and well deserves the authority and popularity it has obtained.—*British Med Journ*, Oct. 31, 1874.

Few works of this class exhibit a grander monument of patient research and of scientific lore. The extent of the sale of this lexicon is sufficient to testify to its usefulness, and to the great service conferred by Dr. Robley Dunglison on the profession, and indeed on others, by its issue.—*London Lancet*, May 13 1875.

HOBLYN (*RICHARD D.*), *M.D.*

A DICTIONARY OF THE TERMS USED IN MEDICINE AND THE COLLATERAL SCIENCES. Revised, with numerous additions, by ISAAC HAYS, M.D., Editor of the "American Journal of the Medical Sciences." In one large royal 12mo. volume of over 500 double-columned pages; cloth, $1 50; leather, $2 00

It is the best book of definitions we have, and ought always to be upon the student's table.—*Southern M. and Surg. Journal.*

LADWELL (*G. F.*), *F.R.A.S., &c.*

A DICTIONARY OF SCIENCE: Comprising Astronomy, Chemistry, Dynamics, Electricity, Heat, Hydrodynamics, Hydrostatics, Light, Magnetism, Mechanics, Meteorology, Pneumatics, Sound, and Statics. Preceded by an Essay on the History of the Physical Sciences. In one handsome octavo volume of 694 pages, with many illustrations: cloth, $5.

A *CENTURY OF AMERICAN MEDICINE*, 1776–1876. By Doctors E. H. Clarke, H. J. Bigelow, S. D. Gross, T. G. Thomas, and J. S. Billings. In one very handsome 12mo. volume of about 350 pages: cloth, $2 25. (*Lately Issued.*)

This work appeared in the pages of the American Journal of the Medical Sciences during the year 1876. As a detailed account of the development of medical science in America, by gentlemen of the highest authority in their respective departments, the profession will no doubt welcome it in a form adapted for preservation and reference.

NEILL (*JOHN*), *M.D.*, *and* SMITH (*FRANCIS G.*), *M.D.*,
Prof. of the Institutes of Medicine in the Univ. of Penna.

AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE; for the Use and Examination of Students. A new edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of about one thousand pages, with 374 wood-cuts, cloth, $4; strongly bound in leather, with raised bands, $4 75.

HARTSHORNE (*HENRY*), *M.D.*,
Professor of Hygiene in the University of Pennsylvania.

A CONSPECTUS OF THE MEDICAL SCIENCES; containing Handbooks on Anatomy, Physiology, Chemistry, Materia Medica, Practical Medicine, Surgery, and Obstetrics. Second Edition, thoroughly revised and improved. In one large royal 12mo. volume of more than 1000 closely printed pages, with 477 illustrations on wood. Cloth, $4 25; leather, $5 00. (*Lately Issued.*)

We can say with the strictest truth that it is the best work of the kind with which we are acquainted. It embodies in a condensed form all recent contributions to practical medicine, and is therefore useful to every busy practitioner throughout our country, besides being admirably adapted to the use of students of medicine. The book is faithfully and ably executed.—*Charleston Med. Journ.*, April, 1876

The work is intended as an aid to the medical student, and as such appears to admirably fulfil its object by its excellent arrangement, the full compilation of facts, the perspicuity and terseness of language, and the clear and instructive illustrations in some parts of the work.—*American Journ. of Pharmacy*, Philadelphia, July, 1874.

The volume will be found useful, not only to students, but to many others who may desire to refresh their memories with the smallest possible expenditure of time.—*N. Y. Med. Journal*, Sept. 1874.

The student will find this the most convenient and useful book of the kind on which he can lay his hand.—*Pacific Med. and Surg. Journ.*, Aug. 1874.

This is the best book of its kind that we have ever examined. It is an honest, accurate, and concise compend of medical sciences, as fairly as possible representing their present condition. The changes and the additions have been so judicious and thorough as to render it, so far as it goes, entirely trustworthy. If students must have a conspectus, they will be wise to procure that of Dr Hartshorne.—*Detroit Rev. of Med. and Pharm.*, Aug 1874

The work before us has many redeeming features not possessed by others, and is the best we have seen. Dr. Hartshorne exhibits much skill in condensation. It is well adapted to the physician in active practice, who can give but limited time to the familiarizing of himself with the important changes which have been made since he attended lectures. The manual of physiology has also been improved and gives the most comprehensive view of the late t advances in the science possible in the space devoted to the subject. The mechanical execution of the book leaves nothing to be wished for.—*Peninsular Journal of Medicine*, Sept 1874.

After carefully looking through this conspectus, we are constrained to say that it is the most complete work, especially in its illustrations, of its kind that we have seen.—*Cincinnati Lancet*, Sept. 1874.

The favor with which the first edition of this Compendium was received, was an evidence of its various excellences. The present edition bears evidence of a careful and thorough revision. Dr. Hartshorne possesses a happy faculty of seizing upon the salient points of each subject, and of presenting them in a concise and yet perspicuous manner.—*Leavenworth Med. Herald*, Oct. 1874

LUDLOW (*J. L.*), *M.D.*

A MANUAL OF EXAMINATIONS upon Anatomy, Physiology, Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy, and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised and greatly extended and enlarged. With 370 illustrations. In one handsome royal 12mo. volume of 816 large pages. Cloth, $3 25; leather, $3 75.

The arrangement of this volume in the form of question and answer renders it especially suitable for the office examination of students, and for those preparing for graduation.

TANNER (*THOMAS HAWKES*), *M.D., &c.*

A MANUAL OF CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS. Third American from the Second London Edition. Revised and Enlarged by TILBURY FOX, M. D., Physician to the Skin Department in University College Hospital, London, &c. In one neat volume small 12mo., of about 375 pages, cloth, $1 50.

*** On page 3, it will be seen that this work is offered as a premium for procuring new subscribers to the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES."

GRAY (HENRY), F.R.S.,

Lecturer on Anatomy at St. George's Hospital, London.

ANATOMY, DESCRIPTIVE AND SURGICAL.

The Drawings by H. V. CARTER, M.D., and Dr. WESTMACOTT. The Dissections jointly by the AUTHOR and Dr. CARTER. With an Introduction on General Anatomy and Development by T. HOLMES, M.A., Surgeon to St. George's Hospital. A new American, from the Eighth enlarged and improved London edition. To which is added "LANDMARKS, MEDICAL AND SURGICAL," by LUTHER HOLDEN, F.R.C.S., author of "Human Osteology," "A Manual of Dissections," etc. In one magnificent imperial octavo volume of 983 pages, with 522 large and elaborate engravings on wood. Cloth, $6; leather, raised bands, $7; half Russia, $7 50. (*Now Ready.*)

The author has endeavored in this work to cover a more extended range of subjects than is customary in the ordinary text-books, by giving not only the details necessary for the student, but also the application of those details in the practice of medicine and surgery, thus rendering it both a guide for the learner, and an admirable work of reference for the active practitioner. The engravings form a special feature in the work, many of them being the size of nature, nearly all original, and having the names of the various parts printed on the body of the cut, in place of figures of reference, with descriptions at the foot. They thus form a complete and splendid series which will greatly assist the student in obtaining a clear idea of Anatomy, and will also serve to refresh the memory of those who may find in the exigencies of practice the necessity of recalling the details of the dissecting room; while combining, as it does, a complete Atlas of Anatomy, with a thorough treatise on systematic, descriptive, and applied Anatomy, the work will be found of essential use to all physicians who receive students in their offices, relieving both preceptor and pupil of much labor in laying the groundwork of a thorough medical education.

Since the appearance of the last American Edition, the work has received three revisions at the hands of its accomplished editor, Mr. Holmes, who has sedulously introduced whatever has seemed requisite to maintain its reputation as a complete and authoritative standard text-book and work of reference. Still further to increase its usefulness, there has been appended to it the recent work by the distinguished anatomist, Mr. Luther Holden—"Landmarks, Medical and Surgical"—which gives in a clear, condensed and systematic way, all the information by which the practitioner can determine from the external surface of the body the position of internal parts. The complete, the work, it is believed, will furnish all the assistance that can be rendered by typical illustration in anatomical study. No pains have been spared in the typographical execution of the volume, which will be found in all respects superior to former issues. Notwithstanding the increase of size, amounting to over 100 pages and 57 illustrations, it will be kept, as heretofore, at a price rendering it one of the cheapest works ever offered to the American profession.

The recent work of Mr. Holden, which was noticed by us on p. 53 of this volume, has been added as an appendix, so that, altogether, this is the most practical and complete anatomical treatise available to American students and physicians. The former finds in it the necessary guide in making dissections; a very comprehensive chapter on minute anatomy; and about all that can be taught him on general and special anatomy; while the latter, in its treatment of each region from a surgical point of view, and in the valuable addition of Mr. Holden, will find all that will be essential to him in his practice.—*New Remedies*, Aug 1878.

This work is as near perfection as one could possibly or reasonably expect any book intended as a text-book or a general reference book on anatomy to be. The American publisher deserves the thanks of the profession for appending the recent work of Mr. Holden, "*Landmarks, Medical and Surgical*," which has already been commended as a separate book. The latter work—treating of topographical anatomy—has become an essential to the library of every intelligent practitioner. We know of no book that can take its place, written as it is by a most distinguished anatomist. It would be simply a waste of words to say anything further in praise of Gray's Anatomy, the text-book in almost every medical college in this country, and the daily reference book of every practitioner who has occasion to consult his books on anatomy. The work is simply indispensable, especially this present American edition.—*Va. Med. Monthly*, Sept. 1878.

The addition of the recent work of Mr. Holden, as an appendix, renders this the most practical and complete treatise available to American students, who find in it a comprehensive chapter on minute anatomy, about all that can be taught on general and special anatomy, while its treatment of each region, from a surgical point of view, in the valuable section by Mr Holden, is all that will be essential to them in practice.—*Ohio Medical Recorder*, Aug 1878.

It is difficult to speak in moderate terms of this new edition of "Gray." It seems to be as nearly perfect as it is possible to make a book devoted to any branch of medical science. The labors of the eminent men who have successively revised the eight editions through which it has passed, would seem to leave nothing for future editors to do. The addition of Holden's "Landmarks" will make it indispensable to the practitioner of medicine and surgery as it has been heretofore to the student. As regards completeness, ease of reference, utility, beauty, and cheapness, it has no rival. No student should enter a medical school without it; no physician can afford to have it absent from his library.—*St. Louis Clin. Record*, Sept. 1878.

ALSO FOR SALE SEPARATE—

HOLDEN (LUTHER), F.R.C.S.,

Surgeon to St. Bartholomew's and the Foundling Hospitals.

LANDMARKS, MEDICAL AND SURGICAL.

From the 2d London Ed. In one handsome volume, royal 12mo., of 128 pages. Cloth, 88 cents. (*Now Ready.*)

HEATH (CHRISTOPHER), F.R.C.S.,

Teacher of Operative Surgery in University College, London.

PRACTICAL ANATOMY: A Manual of Dissections.

From the Second revised and improved London edition. Edited, with additions, by W. W. Keen, M. D., Lecturer on Pathological Anatomy in the Jefferson Medical College, Philadelphia. In one handsome royal 12mo. volume of 578 pages, with 247 illustrations. Cloth, $3 50; leather, $4 00.

ALLEN (HARRISON), M.D.
Professor of Physiology in the Univ. of Pa.

A SYSTEM OF HUMAN ANATOMY: INCLUDING ITS MEDICAL and Surgical Relations. For the Use of Practitioners and Students of Medicine With an Introductory Chapter on Histology. By E. O. SHAKESPEARE, M D, Ophthalmologist to the Phila. Hosp. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text. (*Shortly.*)

In this elaborate work, which has been in active preparation for several years, the author has sought to give, not only the details of descriptive anatomy in a clear and condensed form, but also the practical applications of the science to medicine and surgery. The work thus has claims upon the attention of the general practitioner, as well as of the student, enabling him not only to refresh his recollections of the dissecting room, but also to recognize the significance of all variations from normal conditions. The marked utility of the object thus sought by the author is self-evident, and his long experience and assiduous devotion to its thorough development are a sufficient guarantee of the manner in which his aims have been carried out. No pains have been spared with the illustrations. Those of normal anatomy are from original dissections, drawn on stone by Mr. Hermann Faber, with the name of every part clearly engraved upon the figure, after the manner of "Holden" and "Gray," and in every typographical detail it will be the effort of the publishers to render the volume worthy of the very distinguished position which is anticipated for it.

ELLIS (GEORGE VINER).
Emeritus Professor of Anatomy in University College, London.

DEMONSTRATIONS OF ANATOMY; Being a Guide to the Knowledge of the Human Body by Dissection. By GEORGE VINER ELLIS, Emeritus Professor of Anatomy in University College, London. From the Eighth and Revised London Edition. In one very handsome octavo volume of over 700 pages, with 256 illustrations. Cloth, $4.25; leather, $5.25. (*Now Ready.*)

This work has long been known in England as the leading authority on practical anatomy, and the favorite guide in the dissecting-room, as is attested by the numerous editions through which it has passed. In the last revision, which has just appeared in London, the accomplished author has sought to bring it on a level with the most recent advances of science by making the necessary changes in his account of the microscopic structure of the different organs, as developed by the latest researches in textural anatomy.

Ellis's Demonstrations is the favorite text-book of the English student of anatomy. In passing through eight editions it has been so revised and adapted to the needs of the student that it would seem that it had almost reached perfection in this special line. The descriptions are clear, and the methods of pursuing anatomical investigations are given with such detail that the book is honestly entitled to its name.—*St. Louis Clinical Record*, June, 1879.

The success of this old manual seems to be as well deserved in the present as in the past volumes. The book seems destined to maintain yet for years its leadership over the English manuals upon dissecting.—*Phila. Med. Times*, May 24, 1879.

As a dissector, or a work to have in hand and studied while one is engaged in dissecting, we regard it as the very best work extant, which is certainly saying a very great deal. As a text-book to be studied in the dissecting-room, it is superior to any of the works upon anatomy.—*Cincinnati Med. News*, May 24, 1879.

We most unreservedly recommend it to every practitioner of medicine who can possibly get it.—*Va. Med. Monthly*, June, 1879.

WILSON (ERASMUS), F.R.S.

A SYSTEM OF HUMAN ANATOMY, General and Special. Edited by W. H. GOBRECHT, M.D., Professor of General and Surgical Anatomy in the Medical College of Ohio. Illustrated with three hundred and ninety-seven engravings on wood. In one large and handsome octavo volume, of over 600 pages; cloth, $4; leather, $5.

SMITH (HENRY H.), M.D., and HORNER (WILLIAM E.), M.D.,
Prof. of Surgery in the Univ. of Penna., &c. *Late Prof. of Anatomy in the Univ. of Penna.*

AN ANATOMICAL ATLAS; Illustrative of the Structure of the Human Body. In one volume, large imperial octavo, cloth, with about six hundred and fifty beautiful figures. $4 50.

SCHÄFER (EDWARD ALBERT), M.D.,
Assistant Professor of Physiology in University College, London.

A COURSE OF PRACTICAL HISTOLOGY: Being an Introduction to the Use of the Microscope. In one handsome royal 12mo. volume of 304 pages, with numerous illustrations: cloth, $2 00. (*Just Issued.*)

HENLE'S SPECIAL ANATOMY AND HISTOLOGY. Eighth edition, extensively revised and modified. In 2 vols. 8vo., of over 1000 pages, with 320 wood-cuts: cloth, $6 00

HARPEY AND QUAIN'S HUMAN ANATOMY. Revised, by JOSEPH LEIDY, M.D., Prof of Anat. in Univ. of Penn. In two octavo vols. of about 1200 pages, with 511 illustrations Cloth, $6 00.

WILLAMY'S STUDENT'S GUIDE TO SURGICAL ANATOMY: A Text-book for Students preparing for their Pass Examination. With engravings on wood. In one handsome royal 12mo. volume. Cloth, $2 25.

CLELAND'S DIRECTORY FOR THE DISSECTION OF THE HUMAN BODY. In one small volume, royal 12mo. of 182 pages: cloth $1 25.

HARTSHORNE'S HANDBOOK OF ANATOMY AND PHYSIOLOGY. Second edition, revised. In one royal 12mo. vol., with 220 wood-cuts; cloth, $1 75.

DALTON (*J. C.*), *M.D.*,

Professor of Physiology in the College of Physicians and Surgeons, New York, &c.

A TREATISE ON HUMAN PHYSIOLOGY. Designed for the use of Students and Practitioners of Medicine. Sixth edition, thoroughly revised and enlarged, with three hundred and sixteen illustrations on wood. In one very beautiful octavo volume, of over 800 pages. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Lately Issued.*)

During the past few years several new works on physiology, and new editions of old works, have appeared, competing for the favor of the medical student, but none will rival this new edition of Dalton. As now enlarged, it will be found also to be, in general, a satisfactory work of reference for the practitioner.—*Chicago Med. Journ. and Examiner*, Jan. 1876.

Prof. Dalton has discussed conflicting theories and conclusions regarding physiological questions with a fairness, a fulness, and a conciseness which lend freshness and vigor to the entire book. But his discussions have been so guarded by a refusal of admission to those speculative and theoretical explanations, which at best exist in the minds of observers themselves as only probabilities, that none of his readers need be led into grave errors while making them a study.—*The Medical Record*, Feb. 19, 1876.

The revision of this great work has brought it forward with the physiological advances of the day, and renders it, as it has ever been, the finest work for students extant.—*Nashville Journ. of Med. and Surg.*, Jan. 1876.

For clearness and perspicuity, Dalton's Physiology commended itself to the student years ago, and was a pleasant relief from the verbose productions which it supplanted. Physiology has, however, made many advances since then—and while the style has been preserved intact, the work in the present edition has been brought up fully abreast of the times. The new chemical notation and nomenclature have also been introduced into the present edition. Notwithstanding the multiplicity of text-books on physiology, this will lose none of its old time popularity. The mechanical execution of the work is all that could be desired.—*Peninsular Journal of Medicine*, Dec. 1875.

This popular text-book on physiology comes to us in its sixth edition with the addition of about fifty per cent. of new matter, chiefly in the departments of pathological chemistry and the nervous system, where the principal advances have been realized. With so thorough revision and additions, that keep the work well up to the times, its continued popularity may be confidently predicted, notwithstanding the competition it may encounter. The publisher's work is admirably done.—*St. Louis Med. and Surg. Journ.*, Dec. 1875

We heartily welcome this, the sixth edition of this admirable text-book, than which there are none of equal brevity more valuable. It is cordially recommended by the Professor of Physiology in the University of Louisiana, as by all competent teachers in the United States and wherever the English language is read, this book has been appreciated. The present edition, with its 316 admirably executed illustrations, has been carefully revised and very much enlarged, although its bulk does not seem perceptibly increased.—*New Orleans Medical and Surgical Journal*, March, 1876.

CARPENTER (*WILLIAM B.*), *M. D.*, *F. R. S.*, *F.G.S.*, *F.L.S.*,

Registrar to University of London, etc

PRINCIPLES OF HUMAN PHYSIOLOGY; Edited by HENRY POWER, M.B. Lond., F.R.C.S., Examiner in Natural Sciences, University of Oxford. A new American from the Eighth Revised and Enlarged English Edition, with Notes and Additions, by FRANCIS G. SMITH, M.D., Professor of the Institutes of Medicine in the University of Pennsylvania, etc. In one very large and handsome octavo volume, of 1083 pages, with two plates and 373 engravings on wood. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Issued.*)

We have been agreeably surprised to find the volume so complete in regard to the structure and functions of the nervous system in all its relations, a subject that, in many respects, is one of the most difficult of all, in the whole range of physiology, upon which to produce a full and satisfactory treatise of the class to which the one before us belongs. The additions by the American editor give to the work as it is a considerable value beyond that of the last English edition. In conclusion, we can give our cordial recommendation to the work as it now appears. The editors have, with their additions to the only work on physiology in our language that, in the fullest sense of the word, is the production of a philosopher as well as a physiologist, brought it up as fully as could be expected, if not desired, to the standard of our knowledge of its subject at the present day. It will deservedly maintain the place it has always had in the favor of the medical profession.—*Journ. of Nervous and Mental Disease*, April, 1877.

Such enormous advances have recently been made in our physiological knowledge, that what was perfectly new a year or two ago, looks now as if it had been a received and established fact for years. In this encyclopedic way it is unrivalled. Here, as it seems to us, is the great value of the book; one is safe in sending a student to it for information on almost any given subject, perfectly certain of the fulness of information it will convey, and well satisfied of the accuracy with which it will there be found stated.—*London Med. Times and Gazette*, Feb. 17, 1877.

The merits of "Carpenter's Physiology" are so widely known and appreciated that we need only allude briefly to the fact that in the latest edition will be found a comprehensive embodiment of the results of recent physiological investigation. Care has been taken to preserve the practical character of the original work. In fact the entire work has been brought up to date, and best evidence of the amount of labor that has been bestowed upon it by its distinguished editor, Mr. Henry Power. The American editor has made the latest additions, in order fully to cover the time that has elapsed since the last English edition.—*N. Y. Med. Journal*, Jan. 1877.

FOSTER (*MICHAEL*), *M.D.*, *F.R.S.*,

Prof. of Physiology in Cambridge Univ., England.

TEXT-BOOK OF PHYSIOLOGY. Latest edition. In one handsome 12mo. vol. of over 800 pages, with 72 illustrations. Cloth, $3 00. (*Just Ready.*)

Dr. Foster has combined in this work the conflicting desiderata in all text-books—comprehensiveness, brevity, and clearness. After a careful perusal of the whole work we can confidently recommend it, both to the student and the practitioner, as being one of the best text-books on physiology extant.—*The London Lancet.*

LEHMANN'S MANUAL OF CHEMICAL PHYSIOLOGY. Translated from the German, with Notes and Additions, by J. CHESTON MORRIS, M.D. With Illustrations on wood. In one octavo volume of 336 pages. Cloth, $2 25.

LEHMANN'S PHYSIOLOGICAL CHEMISTRY. Complete in two large octavo volumes of 1300 pages, with 200 illustrations; cloth, $6.

ATTFIELD (JOHN), Ph.D.,

Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, &c.

CHEMISTRY, GENERAL, MEDICAL, AND PHARMACEUTICAL;

Including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. Eighth edition, revised by the author. In one handsome royal 12mo. volume of 700 pages, with illustrations. Cloth, $2 50; leather, $3 00. (*Now Ready.*)

We have repeatedly expressed our favorable opinion of this work, and on the appearance of a new edition of it, little remains for us to say, except that we expect this eighth edition to be as indispensable to us as the seventh and previous editions have been. While the general plan and arrangement have been adhered to, new matter has been added covering the observations made since the former edition. The present differs from the preceding one chiefly in these alterations and in about ten pages of useful tables added in the appendix.—*Am. Jour. of Pharmacy*, May, 1879.

A standard work like Attfield's Chemistry need only be mentioned by its name, without further comments. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. The author has bestowed arduous labor on the revision, and the extent of the information thus introduced may be estimated from the fact that the index contains three hundred new references relating to additional material.—*Druggists' Circular and Chemical Gazette*, May, 1879.

This very popular and meritorious work has now reached its eighth edition, which fact speaks in the highest terms in commendation of its excellence. It has now become the principal text-book of chemistry in all the medical colleges in the United States. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. It is scarcely necessary for us to say that it exhibits chemistry in its present advanced state.—*Cincinnati Medical News*, April, 1879.

The popularity which this work has enjoyed is owing to the original and clear disposition of the facts of the science, the accuracy of the details, and the omission of much which freights many treatises heavily without bringing corresponding instruction to the reader. Dr. Attfield writes for students, and primarily for medical students; he always has an eye to the pharmacopœia and its official preparations; and he is continually putting the matter in the text so that it responds to the questions with which each section is provided. Thus the student learns easily, and can always refresh and test his knowledge.—*Med and Surg. Reporter*, April 19, '79.

We noticed only about two years and a half ago the publication of the preceding edition, and remarked upon the exceptionally valuable character of the work. The work now includes the whole of the chemistry of the pharmacopœia of the United States, Great Britain, and India.—*New Remedies*, May, 1879.

GREENE (WILLIAM H.), M.D.,

Demonstrator of Chemistry in Med. Dept., Univ. of Penna.

A MANUAL OF MEDICAL CHEMISTRY. For the Use of Students.

Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 312 pages. With illustrations. Cloth, $1 75. (*Now Ready.*)

It is well written, and gives the latest views on vital chemistry, a subject with which most physicians are not sufficiently familiar. To those who may wish to improve their knowledge in that direction, we can heartily recommend this work as being worthy of a careful perusal.—*Phila. Med. and Surg. Reporter*, April 24, 1880.

The little work before us is one which we think will be studied with pleasure and profit. The descriptions, though brief, are clear, and in most cases sufficient for the purpose. This book will, in nearly all cases, meet general approval.—*Am. Journ. of Pharmacy*, April, 1880.

CLASSEN (ALEXANDER),

Professor in the Royal Polytechnic School, Aix-la-Chapelle.

ELEMENTARY QUANTITATIVE ANALYSIS. Translated with

notes and additions by EDGAR F. SMITH, Ph.D., Assistant Prof. of Chemistry in the Towne Scientific School, Univ. of Penna. In one handsome royal 12mo. volume, of 324 pages, with illustrations; cloth, $2 00. (*Just Ready.*)

It is probably the best manual of an elementary nature extant, inasmuch as its methods are the best. It teaches by examples, commencing with single determinations, followed by separations, and then advancing to the analysis of minerals and such products as are met with in applied chemistry. It is an indispensable book for students in chemistry.—*Boston Journ. of Chemistry*, Oct. 1878.

GALLOWAY (ROBERT), F.C.S.,

Prof of Applied Chemistry in the Royal College of Science for Ireland, etc.

A MANUAL OF QUALITATIVE ANALYSIS. From the Fifth London Edition. In one neat royal 12mo. volume, with illustrations; cloth, $2 75. (*Lately Issued.*)

REMSEN (IRA), M.D., Ph.D.,

Professor of Chemistry in the Johns Hopkins University, Baltimore.

PRINCIPLES OF THEORETICAL CHEMISTRY, with special reference

to the Constitution of Chemical Compounds. In one handsome royal 12mo. vol. of over 232 pages: cloth, $1 50. (*Just Issued.*)

BOWMAN'S INTRODUCTION TO PRACTICAL CHEMISTRY, INCLUDING ANALYSIS. Sixth American, from the sixth and revised London edition. With numerous illustrations. In one neat vol., royal 12mo., cloth, $2 25.

WÖHLER AND FITTIG'S OUTLINES OF ORGANIC CHEMISTRY. Translated with additions from the Eighth German Edition. By IRA REMSEN, M.D., Ph.D., Prof. of Chemistry and Physics in Williams College, Mass. In one volume, royal 12mo. of 550 pp., cloth, $3.

FOWNES (GEORGE), Ph.D.

A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and Practical.

Revised and corrected by HENRY WATTS, B.A., F R.S., author of "A Dictionary of Chemistry," etc. With a colored plate, and one hundred and seventy-seven illustrations. A new American, from the twelfth and enlarged London edition. Edited by ROBERT BRIDGES, M.D. In one large royal 12mo. volume, of over 1000 pages; cloth, $2 75; leather, $3 25. (*Just Issued.*)

This work, inorganic and organic, is complete in one convenient volume. In its earliest editions it was fully up to the latest advancements and theories of that time. In its present form, it presents, in a remarkably convenient and satisfactory manner, the principles and leading facts of the chemistry of *to-day*. Concerning the manner in which the various subjects are treated, much deserves to be said, and mostly, too, in praise of the book. A review of such a work as *Fownes's Chemistry* within the limits of a book-notice for a medical weekly is simply out of the question.—*Cincinnati Lancet and Clinic*, Dec. 14, 1878.

When we state that, in our opinion, the present edition sustains in every respect the high reputation which its predecessors have acquired and enjoyed, we express therewith our full belief in its intrinsic value as a text-book and work of reference.—*Am. Journ. of Pharm.*, Aug. 1878.

The conscientious care which has been bestowed upon it by the American and English editors renders it still, perhaps, the best book for the student and the practitioner who would keep alive the acquisitions of his student days. It has, indeed, reached a somewhat formidable magnitude with its more than a thousand pages, but with less than this no fair representation of chemistry as it now is can be given. The type is small but very clear, and the sections are very lucidly arranged to facilitate study and reference.—*Med. and Surg. Reporter*, Aug 3, 1878.

The work is too well known to American students to need any extended notice; suffice it to say that the revision by the English editor has been faithfully done, and that Professor Bridges has added some fresh and valuable matter, especially in the inorganic chemistry. The book has always been a favorite in this country, and in its new shape bids fair to retain all its former *prestige*.—*Boston Jour. of Chemistry*, Aug. 1878.

It will be entirely unnecessary for us to make any remarks relating to the general character of Fownes' Manual. For over twenty years it has held *the* foremost place as a text-book, and the elaborate and thorough revisions which have been made from time to time leave little chance for any wide awake rival to step before it.—*Canadian Pharm. Jour.*, Aug. 1878.

As a manual of chemistry it is without a superior in the language.—*Md. Med. Jour.*, Aug. 1878.

BLOXAM (C. L.),

Professor of Chemistry in King's College, London.

CHEMISTRY, INORGANIC AND ORGANIC.

From the Second London Edition. In one very handsome octavo volume, of 700 pages, with about 300 illustrations. Cloth, $4 00; leather, $5 00. (*Lately Issued.*)

We have in this work a complete and most excellent text-book for the use of schools, and can heartily recommend it as such.—*Boston Med. and Surg. Journ.*, May 23, 1874.

The above is the title of a work which we can most conscientiously recommend to students of chemistry. It is as easy as a work on chemistry could be made, at the same time that it presents a full account of that science as it now stands. We have spoken of the work as admirably adapted to the wants of students; it is quite as well suited to the requirements of practitioners who wish to review their chemistry, or have occasion to refresh their memories on any point relating to it. In a word, it is a book to be read by all who wish to know what is the chemistry of the present day.—*American Practitioner*, Nov. 1873.

It would be difficult for a practical chemist and teacher to find any material fault with this most admirable treatise. The author has given us almost a cyclopædia within the limits of a convenient volume, and has done so without penning the *useless* paragraphs too commonly making up a great part of the bulk of many cumbrous works. The progressive scientist is not disappointed when he looks for the record of new and valuable processes and discoveries, while the cautious conservative does not find the pages monopolized by uncertain theories and speculations. A peculiar point of excellence is the crystallized form of expression in which great truths are expressed in very short paragraphs. One is surprised at the brief space allotted to an important topic, and yet, after reading it, he feels that little, if any more should have been said. Altogether, it is seldom you see a text-book so nearly faultless. — *Cincinnati Lancet*, Nov. 1873.

CLOWES (FRANK), D.Sc., London.

Senior Science-Master at the High School, Newcastle-under-Lyme, etc.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS.

Specially adapted for Use in the Laboratories of Schools and Colleges and by Beginners. Second American from the Third and Revised English Edition. In one very handsome royal 12mo. volume of 372 pages, with 47 illustrations. Cloth, $2 50. (*Just Ready.*)

A few notices of the previous edition are appended.

It is short, concise, and eminently practical. We therefore heartily commend it to students, and especially to those who are obliged to dispense with a master. Of course, a teacher is in every way desirable, but a good degree of technical skill and practical knowledge can be attained with no other instructor than the very valuable handbook now under consideration.—*St Louis Clin. Record*, Oct. 1877.

The work is so written and arranged that it can be comprehended by the student without a teacher, and the descriptions and directions for the various work are so simple, and yet concise, as to be interesting and intelligible. The work is unincumbered with theoretical deductions, dealing wholly with the practical matter, which it is the aim of this comprehensive text-book to impart. The accuracy of the analytical methods are vouched for from the fact that they have all been worked through by the author and the members of his class, from the printed text. We can heartily recommend the work to the student of chemistry as being a reliable and comprehensive one.—*Druggists' Advertiser*, Oct. 15, 1877.

KNAPP'S TECHNOLOGY; or Chemistry Applied to the Arts and to Manufactures. With American additions by Prof. WALTER R. JOHNSON. In two very handsome octavo volumes, with 500 wood engravings, cloth, $6 00.

PARRISH (*EDWARD*),

Late Professor of Materia Medica in the Philadelphia College of Pharmacy.

A TREATISE ON PHARMACY. Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmaceutist. With many Formulæ and Prescriptions. Fourth Edition, thoroughly revised, by THOMAS S. WIEGAND. In one handsome octavo volume of 977 pages, with 280 illustrations; cloth, $5 50; leather, $6 50; half Russia, $7. (*Lately Issued.*)

Of Dr. Parrish's great work on pharmacy it only remains to be said that the editor has accomplished his work so well as to maintain, in this fourth edition, the high standard of excellence which it had attained in previous editions, under the editorship of its accomplished author. This has not been accomplished without much labor, and many additions and improvements, involving changes in the arrangement of the several parts of the work, and the addition of much new matter. With the modifications thus effected it constitutes, as now presented, a compendium of the science and art indispensable to the pharmacist, and of the utmost value to every practitioner of medicine desirous of familiarising himself with the pharmaceutical preparation of the articles which he prescribes for his patients.—*Chicago Med. Journ.*, July, 1874.

The work is eminently practical, and has the rare merit of being readable and interesting, while it preserves a strictly scientific character. The whole work reflects the greatest credit on author, editor and publisher. It will convey some idea of the liberality which has been bestowed upon its production when we mention that there are no less than 280 carefully executed illustrations. In conclusion, we heartily recommend the work, not only to pharmacists, but also to the multitude of medical practitioners who are obliged to compound their own medicines. It will ever hold an honored place on our own bookshelves.—*Dublin Med. Press and Circular*, Aug. 12, 1874.

We expressed our opinion of a former edition in terms of unqualified praise, and we are in no mood to detract from that opinion in reference to the present edition, the preparation of which has fallen into competent hands. It is a book with which no pharmacist can dispense, and from which no physician can fail to derive much information of value to him in practice.—*Pacific Med. and Surg. Journ.*, June, '74.

Perhaps one, if not the most important book upon pharmacy which has appeared in the English language has emanated from the transatlantic press. "Parrish's Pharmacy" is a well-known work on this side of the water, and the fact shows us that a really useful work never becomes merely local in its fame. Thanks to the judicious editing of Mr. Wiegand, the posthumous edition of "Parrish" has been saved to the public with all the mature experience of its author, and perhaps none the worse for a dash of new blood.—*Lond. Pharm. Journal*, Oct. 17, 1874.

GRIFFITH (*ROBERT E.*), *M.D.*

A UNIVERSAL FORMULARY, Containing the Methods of Preparing and Administering Officinal and other Medicines. The whole adapted to Physicians and Pharmaceutists. Third edition, thoroughly revised, with numerous additions, by JOHN M. MAISCH, Professor of Materia Medica in the Philadelphia College of Pharmacy. In one large and handsome octavo volume of about 800 pp., cl., $4 50; leather, $5 50. (*Lately Issued.*)

To the druggist a good formulary is simply indispensable, and perhaps no formulary has been more extensively used than the well-known work before us. Many physicians have to officiate, also, as druggists. This is true especially of the country physician, and a work which shall teach him the means by which to administer or combine his remedies in the most efficacious and pleasant manner, will always hold its place upon his shelf. A formulary of this kind is of benefit also to the city physician in largest practice.—*Cincinnati Clinic*, Feb. 21, 1874.

A more complete formulary than it is in its present form the pharmacist or physician could hardly desire. To the first some such work is indispensable, and it is hardly less essential to the practitioner who compounds his own medicines. Much of what is contained in the introduction ought to be committed to memory by every student of medicine. As a help to physicians it will be found invaluable, and doubtless will make its way into libraries not already supplied with a standard work of the kind.—*The American Practitioner*, Louisville, July, '74.

FARQUHARSON (*ROBERT*), *M.D.*,

Lecturer on Materia Medica at St. Mary's Hospital Medical School.

A GUIDE TO THERAPEUTICS AND MATERIA MEDICA. Second American edition, revised by the Author. Enlarged and adapted to the U. S. Pharmacopœia. By FRANK WOODBURY, M.D. In one neat royal 12mo. volume of 498 pages: cloth, $2.25. (*Just Ready.*)

The appearance of a new edition of this convenient and handy book in less than two years may certainly be taken as an indication of its usefulness. Its convenient arrangement, and its terseness, and, at the same time, completeness of the information given, make it a handy book of reference.—*Am. Journ. of Pharmacy*, June, 1879.

This work contains in moderate compass such well-digested facts concerning the physiological and therapeutical action of remedies as are reasonably established up to the present time. By a convenient arrangement the corresponding effects of each article in health and disease are presented in parallel columns, not only rendering reference easier, but also impressing the facts more strongly upon the mind of the reader. The book has been adapted to the wants of the American student, and copious notes have been introduced, embodying the latest revision of the Pharmacopœia, together with the antidotes to the more prominent poisons, and such of the newer remedial agents as seemed necessary to the completeness of the work. Tables of weights and measures, and a good alphabetical index end the volume.—*Druggists' Circular and Chemical Gazette*, June, 1879.

It is a pleasure to think that the rapidity with which a second edition is demanded may be taken as an indication that the sense of appreciation of the value of reliable information regarding the use of remedies is not entirely overwhelmed in the cultivation of pathological studies, characteristic of the present day. This work certainly merits the success it has so quickly achieved.—*New Remedies*, July, '79.

CHRISTISON'S DISPENSATORY. With copious additions, and 213 large wood engravings. By R. EGLESFIELD GRIFFITH, M.D. One vol. 8vo., pp. 1000, cloth, $4 00.

CARPENTER'S PRIZE ESSAY ON THE USE OF ALCOHOLIC LIQUORS IN HEALTH AND DISEASE. New edition, with a Preface by D. F. CONDIE, M.D., and explanations of scientific words. In one neat 12mo. volume, pp. 178, cloth, 60 cents.

STILLE (*ALFRED*), *M.D., LL.D., and* MAISCH (*JOHN M.*), *Ph.D.*,
Prof. of Theory and Practice of Medicine and of Clinical Med. in Univ. of Pa.
Prof. of Mat. Med. and Bot. in Phila. Coll. Pharmacy, Secy. to the American Pharmaceutical Association.

THE NATIONAL DISPENSATORY: Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of 1692 pages, with 239 illustrations. Extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25. (*Now Ready*)

PREFACE TO THE SECOND EDITION.

The demand which has exhausted in a few months an unusually large edition of the National Dispensatory is doubly gratifying to the authors, as showing that they were correct in thinking that the want of such a work was felt by the medical and pharmaceutical professions, and that their efforts to supply that want have been acceptable. This appreciation of their labors has stimulated them in the revision to render the volume more worthy of the very marked favor with which it has been received. The first edition of a work of such magnitude must necessarily be more or less imperfect; and though but little that is new and important has been brought to light in the short interval since its publication, yet the length of time during which it was passing through the press rendered the earlier portions more in arrears than the later. The opportunity for a revision has enabled the authors to scrutinize the work as a whole, and to introduce alterations and additions wherever there has seemed to be occasion for improvement or greater completeness. The principal changes to be noted are the introduction of several drugs under separate headings, and of a large number of drugs, chemicals, and pharmaceutical preparations classified as allied drugs and preparations under the heading of more important or better known articles: these additions comprise in part nearly the entire German Pharmacopœia and numerous articles from the French Codex. All new investigations which came to the authors' notice up to the time of publication have received due consideration.

The series of illustrations has undergone a corresponding thorough revision. A number have been added, and still more have been substituted for such as were deemed less satisfactory.

The new matter embraced in the text is equal to nearly one hundred pages of the first edition. Considerable as are these changes as a whole, they have been accommodated by an enlargement of the page without increasing unduly the size of the volume.

While numerous additions have been made to the sections which relate to the physiological action of medicines and their use in the treatment of disease, great care has been taken to make them as concise as was possible without rendering them incomplete or obscure. The doses have been expressed in the terms both of troy weight and of the metrical system, for the purpose of making those who employ the Dispensatory familiar with the latter, and paving the way for its introduction into general use.

The Therapeutical Index has been extended by about 2250 new references, making the total number in the present edition about 6000.

The articles there enumerated as remedies for particular diseases are not only those which, in the authors' opinion, are curative, or even beneficial, but those also which have at any time been employed on the ground of popular belief or professional authority. It is often of as much consequence to be acquainted with the worthlessness of certain medicines or with the narrow limits of their power, as to know the well attested virtues of others and the conditions under which they are displayed. An additional value possessed by such an Index is, that it contains the elements of a natural classification of medicines, founded upon an analysis of the results of experience, which is the only safe guide in the treatment of disease.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since the previous publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Jour. of Pharmacy*, Nov. 1879.

It is with great pleasure that we announce to our readers the appearance of a *second* edition of the National Dispensatory. The total exhaustion of the first edition in the short space of six months, is a sufficient testimony to the value placed upon the work by the profession. It appears that the rapid sale of the first edition must have induced both the editors and the publisher to make preparations for a new edition immediately after the first had been issued, for we find a large amount of new matter added and a good deal of the previous text altered and improved, which proves that the authors do not intend to let the grass grow under their feet, but to keep the work up to the time.—*New Remedies*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on the subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only *national*, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Medical Journal*, Nov. 1879.

It is by far more international or universal than any other book of the kind in our language, and more comprehensive in every sense.—*Pacific Med. and Surg. Journ.*, Oct. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practising physician can afford to be without the National Dispensatory.—*Canada Med. and Surg. Journ.*, Feb. 1880.

STILLÉ (*ALFRED*), *M. D.*,

Professor of Theory and Practice of Medicine in the University of Penna.

THERAPEUTICS AND MATERIA MEDICA; a Systematic Treatise

on the Action and Uses of Medicinal Agents, including their Description and History. Fourth edition, revised and enlarged. In two large and handsome 8vo. vols. of about 2000 pages. Cloth, $10: leather, $12; half Russia, $13. (*Lately Issued.*)

It is unnecessary to do much more than to announce the appearance of the fourth edition of this well known and excellent work.—*Brit. and For. Med.-Chir. Review*, Oct 1875.

For all who desire a complete work on therapeutics and materia medica for reference, in cases involving medico-legal questions, as well as for information concerning remedial agents, Dr. Stillé's is "par excellence" the work Being out of print, by the exhaustion of former editions, the author has laid the profession under renewed obligations, by the careful revision, important additions, and timely reissuing a work not exactly supplemented by any other in the English language, if in any language. The mechanical execution handsomely sustains the well-known skill and good taste of the publisher.—*St. Louis Med. and Surg Journal*, Dec 1874.

From the publication of the first edition "Stillé's Therapeutics" has been one of the classics; its absence from our libraries would create a vacuum which could be filled by no other work in the language, and its presence supplies, in the two volumes of the present edition, a whole cyclopædia of therapeutics.—*Chicago Medical Journal*, Feb. 1875.

The rapid exhaustion of three editions and the universal favor with which the work has been received by the medical profession, are sufficient proof of its excellence as a repertory of practical and useful information for the physician. The edition before us fully sustains this verdict, as the work has been carefully revised and in some portions rewritten, bringing it up to the present time by the admission of chloral and croton chloral nitrite of amyl, bichloride of methylene, methylic ether, lithium compounds, gelseminum, and other remedies.—*Am Journ of Pharmacy*, Feb. 1875.

We can hardly admit that it has a rival in the multitude of its citations and the fulness of its research into clinical histories, and we must assign it a place in the physician's library; not, indeed, as fully representing the present state of knowledge in pharmacodynamics, but as by far the most complete treatise upon the clinical and practical side of the question.—*Boston Med. and Surg. Journal*, Nov. 5, 1874.

CORNIL (*V.*). *AND* RANVIER (*L.*).

Prof. in the Faculty of Med., Paris. *Prof in the College of France.*

MANUAL OF PATHOLOGICAL HISTOLOGY. Translated, with

Notes and Additions, by E. O. SHAKESPEARE, M.D., Pathologist and Ophthalmic Surgeon to Philada Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in Univ. of Penna., and by HENRY C. SIMES M D., Demonstrator of Pathological Histology in the Univ. of Pa. In one very handsome octavo volume of over 700 pages, with over 350 illustrations Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Ready.*)

The work of Cornil and Ranvier is so well known as a lucid and accurate text-book on its important subject, that no apology is needed in presenting a translation of it to the American profession. It is only necessary to say that the labors of Drs. Shakespeare and Simes have been by no means confined to the task of rendering the work into English. As it appeared in France, in successive portions, between 1868 and 1876, a part of it, at least, was somewhat in arrears of the present state of science, while the diffuseness of other portions rendered condensation desirable. The translators have, therefore, sought to bring the work up to the day, and, at the same time to reduce it in size, as far as practicable, without impairing its completeness These changes will be found throughout the volume, the most extensive being in the sections devoted to Sarcoma, Carcinoma, Tuberculosis, the Bloodvessels, the Mammæ, and the classification of tumors Corresponding modifications have been made in the very extensive and beautiful series of illustrations, and every care has been taken in the typographical execution to render it one of the most attractive volumes which have issued from the American press.

We have no hesitation in cordially recommending the English translation of Cornil & Ranvier's "Pathological Histology" as the best work of the kind in any language, and as giving to its readers a trustworthy guide in obtaining a broad and solid basis for the appreciation of the practical bearings of pathological anatomy.—*Am. Journ. of Med. Sciences*, April, 1880.

This important work, in its American dress, is a welcome offering to all students of the subjects which it treats. The great mass of material is arranged naturally and comprehensively. The classification of tumors is clear and full, so far as the subject admits of definition, and this one chapter is worth the price of the book The illustrations are copious and well chosen. Without the slightest hesitation, the translators deserve honest thanks for placing this indispensable work in the hands of American students.—*Phila. Med. Times*, April 24, 1880

This volume we cordially commend to the profession. It will prove a valuable, almost necessary, addition to the libraries of students who are to be physicians, and to the libraries of students who are physicians.—*American Practitioner*, June, 1880

Their book is not a collection of the work of others, but has been written in the laboratory beside the microscope. It bears the marks of personal knowledge and investigation upon every page, controlled by and controlling the work of others. . . . In short, its translation has made it the best work in pathology attainable in our language, one that every student certainly ought to have.—*Archives of Medicine*, April, 1880.

This work, in the original, has for years past occupied a prominent place in the library of French pathologists, as we should naturally be led to believe from the reputation of the distinguished authors Now that it has been presented to the English student for the first time, it will be perused with unusual interest. The illustrations are by no means the least valuable part of the work. Indispensable as they are to any work of this nature, in the work before us the artist has succeeded in producing cuts which will prove unusually valuable to the reader. The translation is well done, and gives evidence throughout the volume that it was made by a person thoroughly conversant with the subject.—*N. Y. Med. Gazette*, Feb. 28, 1880.

GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY. Translated, with Notes and Additions, by JOSEPH LEIDY, M. D. In one volume, very large imperial quarto, with 320 copper-plate figures, plain and colored, cloth. $4 00.

PAVY'S TREATISE ON THE FUNCTION OF DIGESTION: its Disorders and their Treatment. From the second London edition In one handsome volume, small octavo, cloth, $2 00.

FENWICK (SAMUEL), M.D.,

Assistant Physician to the London Hospital.

THE STUDENT'S GUIDE TO MEDICAL DIAGNOSIS.

From the Third Revised and Enlarged English Edition. With eighty-four illustrations on wood. In one very handsome volume, royal 12mo., cloth, $2 25. (*Just Issued.*)

GREEN (T. HENRY), M.D.,

Lecturer on Pathology and Morbid Anatomy at Charing-Cross Hospital Medical School, etc.

PATHOLOGY AND MORBID ANATOMY.

Third American, from the Fourth Enlarged and Revised English Edition. In one very handsome octavo volume of 332 pages, with 132 illustrations; cloth, $2 25. (*Now Ready.*)

This is unquestionably one of the best manuals on the subject of pathology and morbid anatomy that can be placed in the student's hands, and we are glad to see it kept up to the times by new editions. Each edition is carefully revised by the author, with the view of making it include the most recent advances in pathology, and of omitting whatever may have become obsolete.—*N. Y. Med. Jour.*, Feb. 1879.

The treatise of Dr. Green is compact, clearly expressed, up to the times, and popular as a text-book, both in England and America. The cuts are sufficiently numerous, and usually well made. In the present edition, such new matter has been added as was necessary to embrace the later results in pathological research. No doubt it will continue to enjoy the favor it has received at the hands of the profession.—*Med. and Surg. Reporter*, Feb. 1, 1879.

For practical, ordinary daily use, this is undoubtedly the best treatise that is offered to students of pathology and morbid anatomy.—*Cincinnati Lancet and Clinic*, Feb. 8, 1879.

BRISTOWE (JOHN SYER), M.D., F.R.C.P.,

Physician and Joint Lecturer on Medicine, St. Thomas's Hospital.

A TREATISE ON THE PRACTICE OF MEDICINE.

Second American edition, revised by the Author. Edited, with Additions, by JAMES H. HUTCHINSON, M.D., Physician to the Penna. Hospital. In one handsome octavo volume of nearly 1200 pages. With illustrations. Cloth, $5 00; leather, $6 00; half Russia, $6 50. (*Now Ready.*)

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. We see no reason to modify the high opinion previously expressed with regard to Dr. Bristowe's work, except by adding our appreciation of the careful labors of the author in following the lateral growth of medical science. The chapter on diseases of the skin and of the nervous system, with a new one on insanity compiled from the best sources outside of the author's own long experience, and the valuable portion relating to general pathology, aid greatly in completing an exceptionally good book for purposes of reference and instruction.—*Boston Medical and Surgical Journal*, February, 1880

What we said of the first edition, we can, with increased emphasis, repeat concerning this: "Every page is characterized by the utterances of a thoughtful man. What has been said, has been well said, and the book is a fair reflex of all that is *certainly known* on the subjects considered."—*Ohio Med. Recorder*, Jan. 7, 1880.

The views of the author are expressed with precision and sufficient promptness to impress the student with the weight of his authority; and should the medical professor differ on any subject from his doctrine, he will need to find strong arguments to carry his class to the opposite conclusion.—*N. O. Med. and Surg. Journ.*, Feb. 1880.

The reader will find every conceivable subject connected with the practice of medicine ably presented, in a style at once clear, interesting, and concise. The additions made by Dr. Hutchinson are appropriate and practical, and greatly add to its usefulness to American readers.—*Buffalo Med. and Surg. Journ.*, March, 1880.

We regard it as an excellent work for students and for practitioners. It is clearly written, the author's style is attractive, and it is especially to be commended for its excellent exposition of the pathology and clinical phenomena of disease.—*St. Louis Clin. Record*, Feb. 1880.

HABERSHON (S. O.). M.D.

Senior Physician to and late Lecturer on the Principles and Practice of Medicine at Guy's Hospital, etc.

ON THE DISEASES OF THE ABDOMEN, COMPRISING THOSE

of the Stomach, and other parts of the Alimentary Canal, Œsophagus, Cæcum, Intestines, and Peritoneum. Second American, from the third enlarged and revised English edition. With illustrations. In one handsome octavo volume of over 500 pages. Cloth, $3 50. (*Now Ready.*)

This valuable treatise on diseases of the stomach and abdomen has been out of print for several years, and is therefore not so well known to the profession as it deserves to be. It will be found a cyclopædia of information, systematically arranged, on all diseases of the alimentary tract, from the mouth to the rectum. A fair proportion of each chapter is devoted to symptoms, pathology, and therapeutics. The present edition is fuller than former ones in many particulars, and has been thoroughly revised and amended by the author. Several new chapters have been added, bringing the work fully up to the times, and making it a volume of interest to the practitioner in every field of medicine and surgery. Perverted nutrition is in some form associated with all diseases we have to combat, and we need all the light that can be obtained on a subject so broad and general. Dr. Habershon's work is one that every practitioner should read and study for himself.—*N. Y. Med. Journ.*, April, 1879.

LA ROCHE ON YELLOW FEVER, considered in its Historical, Pathological, Etiological, and Therapeutical Relations. In two large and handsome octavo volumes of nearly 1500 pp., cloth. $7 00.

STOKES' LECTURES ON FEVER. Edited by JOHN WILLIAM MOORE, M.D., Assistant Physician to the Cork Street Fever Hospital. In one neat 8vo volume, cloth, $2 00.

HOLLAND'S MEDICAL NOTES AND REFLECTIONS. 1 vol. 8vo., pp. 500, cloth. $3 50.

BARLOW'S MANUAL OF THE PRACTICE OF MEDICINE. With Additions by D. F. CONDIE, M D. 1 vol. 8vo., pp. 600, cloth. $2 50.

TODD'S CLINICAL LECTURES ON CERTAIN ACUTE DISEASES. In one neat octavo volume, of 320 pp., cloth. $2 50.

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; designed for the use of Students and Practitioners of Medicine. Fifth edition, entirely rewritten and much improved. In one large and closely printed octavo volume of 1153 pp. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7. (*Just Ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

In preparing the fifth edition of this treatise, the author has been thoroughly mindful of the progress of medicine since the publication of the fourth edition in 1873. Time and labor have not been spared in the endeavor to bring the work in all respects up to the present state of medical knowledge.

Dr. William H. Welch, Lecturer on Pathological Histology in the Bellevue Hospital Medical College, has contributed in Part I. the first seven chapters, embracing the general pathology of the solid tissues and of the blood. He has also revised, and in great part rewritten, the descriptions of the anatomical characters of the diseases considered in the rest of the volume It is believed that these portions of the work will serve as a digest of the essential facts pertaining to general and special pathological anatomy, as far as this important branch of study bears upon practical medicine.

In the other portions of the treatise many changes will be found, which have somewhat enlarged the size of the volume, in spite of the omission of a considerable amount of matter, and the rewriting of many portions with a special view to condensation. Among these changes may be mentioned numerous improvements in the arrangement, including the classification of the diseases of the nervous system on an anatomical in place of a symptomatic basis, and the consideration of various diseases not embraced in previous editions. In short, the eliminations, substitutions, and additions render the present edition virtually a new work.

In making changes, the author has not been influenced by any sense of obligation to maintain consistency of views with the previous editions of this treatise, or with other works which he has written. If statements be found to vary from those made at a prior date, the simple explanation is that the latter, in the light of more recent reflection and enlarged knowledge, seem to him no longer tenable. He has endeavored to regard his own past writings, in this point of view, divested of the partiality of authorship, and to subject them to as critical an examination as if they were the writings of another.

BY THE SAME AUTHOR.

CLINICAL MEDICINE; a Systematic Treatise on the Diagnosis and Treatment of Diseases. Designed for Students and Practitioners of Medicine. In one large and handsome octavo volume of 795 pages; cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

The eminent teacher who has written the volume under consideration has recognized the needs of the American profession, and the result is all that we could wish. The style in which it is written is peculiarly the author's; it is clear and forcible, and marked by those characteristics which have rendered him one of the best writers and teachers this country has ever produced. We have not space for so full a consideration of this remarkable work as we would desire.—*S. Louis Clin. Record*, Oct. 1879.

It is here that the skill and learning of the great clinician are displayed He has given us a storehouse of medical knowledge, excellent for the student, convenient for the practitioner, the result of a long life of the most faithful clinical work, collected by an energy as vigilant and systematic as untiring, and weighed by a judgment no less clear than his observation is close.—*Archives of Medicine*, Dec. 1879

To give an adequate and useful conspectus of the extensive field of modern clinical medicine is a task of no ordinary difficulty; but to accomplish this consistently, with brevity and clearness, the different subjects and their several parts receiving the attention which, relatively to their importance, medical opinion claims for them, is still more difficult. This task we feel bound to say has been executed with more than partial success by Dr. Flint, whose name is already familiar to students of advanced medicine in this country as that of the author of two works of great merit on special subjects, and of numerous papers, exhibiting much originality and extensive research.—*The Dublin Journal*, Dec. 1879.

There is every reason to believe that this book will be well received. The active practitioner is frequently in need of some work that will enable him to obtain information in the diagnosis and treatment of cases with comparatively little labor. Dr. Flint has the faculty of expressing himself clearly, and at the same time so concisely as to enable the searcher to traverse the entire ground of his search, and at the same time obtain all that is essential, without plodding through an interminable space.—*N. Y. Med. Jour.*, Nov. 1879

The great object is to place before the reader the latest observations and experience in diagnosis and treatment. Such a work is especially valuable to students. It is complete in its special design, and yet so condensed, that he can by its aid, keep up with the lectures on practice without neglecting other branches. It will not escape the notice of the practitioner that such a work is most valuable in culling points in diagnosis and treatment in the intervals between the daily rounds of visits since he can in a few minutes refresh his memory, or learn the latest advance in the treatment of diseases which demand his instant attention.—*Cincinnati Lancet and Clinic*, Oct. 25, 1879.

BY THE SAME AUTHOR.

ESSAYS ON CONSERVATIVE MEDICINE AND KINDRED TOPICS. In one very handsome royal 12mo. volume. Cloth, $1 38. (*Just Issued.*)

DAVIS'S CLINICAL LECTURES ON VARIOUS IMPORTANT DISEASES; being a collection of the Clinical Lectures delivered in the Medical Wards of Mercy Hospital, Chicago. Edited by FRANK H DAVIS, M.D. Second edition, enlarged. In one handsome royal 12mo. volume. Cloth, $1 75.

THE CYCLOPÆDIA OF PRACTICAL MEDICINE: comprising Treatises on the Nature and Treatment of Diseases, Materia Medica and Therapeutics, Diseases of Women and Children, Medical Jurisprudence, etc. etc. By DUNGLISON, FORBES, TWEEDIE, and CONOLLY. In four large super-royal octavo volumes, of 3254 double-columned pages, strongly and handsomely bound in leather, $15; cloth, $11.

STURGES'S INTRODUCTION TO THE STUDY OF CLINICAL MEDICINE. Being a Guide to the Investigation of Disease. In one handsome 12mo. volume, cloth, $1 25. (*Lately Issued.*)

RICHARDSON (BENJ. W.), M.D., F.R.S., M.A., LL.D., F.S.A.,

Fellow of the Royal College of Physicians, London.

PREVENTIVE MEDICINE. In one octavo volume of about 500 pages.

(*In Press.*)

The immense strides taken by medical science during the last quarter of a century have had no more conspicuous field of progress than the causation of disease. Not only has this led to marked advance in therapeutics, but it has given rise to a virtually new department of medicine—the prevention of disease—more important, perhaps, in its ultimate results than even the investigation of curative processes. Yet thus far there has been no attempt to gather into a systematic and intelligible shape the accumulation of knowledge thus far acquired on this most interesting subject. Fortunately, the task has been at last undertaken by a writer who of all others is, perhaps, best qualified for its performance, and the result of his labors can hardly fail to mark an epoch in the history of medical science. The plan adopted for the execution of this novel design can best be explained in his own words:—

"With the object here expressed I write this volume. I have nothing to say in it that has any relation to the cure of disease, but I base it nevertheless on the curative side of medical learning. In other words, I trace the diseases from their actual representation as they exist before us, in their natural progress after their birth, as far as I am able, back to their origins, and try to seek the conditions out of which they spring. Thereupon I endeavor further to analyze those conditions, to see how far they are removable and how far they are avoidable."

WOODBURY (FRANK), M.D.,

Physician to the German Hospital, Philadelphia, late Chief Assist. to Med. Clinic, Jeff. College Hospital, etc.

A HANDBOOK OF THE PRINCIPLES AND PRACTICE OF MEDICINE; for the use of Students and Practitioners. Based upon Husband's Handbook of Practice. In one neat volume, royal 12mo. (*Preparing.*)

FOTHERGILL (J. MILNER), M.D. Edin., M.R.C.P. Lond.,

Asst. Phys. to the West Lond. Hosp.; Asst. Phys. to the City of Lond. Hosp., etc.

THE PRACTITIONER'S HANDBOOK OF TREATMENT; Or, the Principles of Therapeutics. Second edition, revised and enlarged. In one very neat octavo volume of about 650 pages. Cloth, $4 00; very handsome half Russia, $5 50. (*Just Ready.*)

The call for a second edition of Dr Fothergill's work has been met by the author with a revision performed in no perfunctory manner. The entire subject-matter has been submitted to a most careful and exhaustive scrutiny, and much new material been added, including articles on "The Functional Disturbances of the Liver," "The Means of Acting on the Respiratory Nerve Centres," "The Reflex Consequences of Ovarian Irritation," "When Not to Give Iron," "Artificial Digestion," etc., thus presenting a complete reflex of the existing condition of therapeutical science.

The junior members of the profession will find in it a work that should not only be read, but carefully studied. It will assist them in the proper selection and combination of therapeutical agents best adapted to each case and condition, and enable them to prescribe intelligently and successfully. To do full justice to a work of this scope and character will be impossible in a review of this kind. The book itself must be read to be fully appreciated. —*St. Louis Courier of Medicine*, Nov 1880.

The author merits the thanks of every well-educated physician for his efforts toward rationalizing the treatment of diseases upon the scientific basis of physiology. Every chapter, every line, has the impress of a master hand, and while the work is thoroughly scientific in every particular, it presents to the thought ul reader all the charms and beauties of a well-written novel. No physician can well afford to be without this valuable work, for its originality makes it fill a niche in medical literature hitherto vacant.—*Nashville Journ. of Med. and Surg.*, Oct. 1880.

To the great bulk of practitioners this work needs no introduction, being already well and favorably known to them. For that class, however, which is ever new, the educated, but inexperienced practitioner, to whom Dr. Fothergill specially addresses himself and to whom probably he is most useful, we may state something of the general character of this work. Throughout the work, while room is left for difference of opinion in matters of detail, the main courses of treatment are so carefully founded on well-established principles, that no essential difference is felt to be possible. The closing chapter contains much concentrated worldly wisdom; and, if carefully read, digested, and assimilated, will, in many an emergency, stand the young medical man in good stead.—*Lond. Med. Record*, Oct. 12, 1880.

WATSON (THOMAS), M.D., &c.

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC. Delivered at King's College, London. A new American, from the Fifth revised and enlarged English edition. Edited, with additions, and several hundred illustrations, by HENRY HARTSHORNE, M.D., Professor of Hygiene in the University of Pennsylvania. In two large and handsome 8vo. vols. Cloth, $9 00; leather, $11 00. (*Lately Published.*)

HARTSHORNE (HENRY), M.D.,

Professor of Hygiene in the University of Pennsylvania

ESSENTIALS OF THE PRINCIPLES AND PRACTICE OF MEDICINE. A handy-book for Students and Practitioners. Fourth edition, revised and improved. With about one hundred illustrations. In one handsome royal 12mo. volume, of about 550 pages, cloth, $2 63; half bound, $2 88. (*Lately Issued.*)

REYNOLDS (J. RUSSELL), M.D.,

Prof. of the Principles and Practice of Medicine in Univ. College, London.

A SYSTEM OF MEDICINE WITH NOTES AND ADDITIONS BY HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Penna. In three large and handsome octavo volumes, containing 3052 closely printed double-columned pages, with numerous illustrations. *Sold only by subscription.* Price per vol., in cloth, $5 00; in sheep, $6.00: half Russia, raised bands, $6.50. Per set in cloth, $15; sheep, $18; half Russia, $19.50

VOLUME I. (*just ready*) contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.

VOLUME II. (*just ready*) contains DISEASES OF RESPIRATORY and CIRCULATORY SYSTEMS.

VOLUME III. (*just ready*) contains DISEASES OF THE DIGESTIVE and BLOOD GLANDULAR SYSTEMS, OF THE URINARY ORGANS, OF THE FEMALE REPRODUCTIVE SYSTEM, and OF THE CUTANEOUS SYSTEM.

Reynolds's SYSTEM OF MEDICINE, recently completed, has acquired, since the first appearance of the first volume, the well deserved reputation of being the work in which modern British medicine is presented in its fullest and most practical form. This could scarce be otherwise in view of the fact that it is the result of the collaboration of the leading minds of the profession, each subject being treated by some gentleman who is regarded as its highest authority—as for instance, Diseases of the Bladder by Sir HENRY THOMPSON, Malpositions of the Uterus by GRAILY HEWITT, Insanity by HENRY MAUDSLEY, Consumption by J. HUGHES BENNET, Diseases of the Spine by CHARLES BLAND RADCLIFFE, Pericarditis by FRANCIS SIBSON, Alcoholism by FRANCIS E. ANSTIE, Renal Affections by WILLIAM ROBERTS, Asthma by HYDE SALTER, Cerebral Affections by H. CHARLTON BASTIAN, Gout and Rheumatism by ALFRED BARING GARROD, Constitutional Syphilis by JONATHAN HUTCHINSON, Diseases of the Stomach by WILSON FOX, Diseases of the Skin by BALMANNO SQUIRE, Affections of the Larynx by MORELL MACKENZIE, Diseases of the Rectum by BLIZARD CURLING, Diabetes by LAUDER BRUNTON, Intestinal Diseases by JOHN SYER BRISTOWE, Catalepsy and Somnambulism by THOMAS KING CHAMBERS, Apoplexy by J. HUGHLINGS JACKSON, Angina Pectoris by Professor GAIRDNER, Emphysema of the Lungs by Sir WILLIAM JENNER, etc etc. All the leading schools in Great Britain have contributed their best men in generous rivalry, to build up this monument of medical science. St. Bartholomew's, Guy's, St Thomas's, University College, St Mary's in London, while the Edinburgh, Glasgow, and Manchester schools are equally well represented, the Army Medical School at Netley, the military and naval services, and the public health boards. That a work conceived in such a spirit, and carried out under such auspices should prove an indispensable treasury of facts and experience, suited to the daily wants of the practitioner, was inevitable, and the success which it has enjoyed in England, and the reputation which it has acquired on this side of the Atlantic, have sealed it with the approbation of the two pre-eminently practical nations.

Its large size and high price having kept it beyond the reach of many practitioners in this country who desire to possess it, a demand has arisen for an edition at a price which shall render it accessible to all. To meet this demand the present edition has been undertaken. The five volumes and five thousand pages of the original have by the use of a smaller type and double columns, been compressed into three volumes of over three thousand pages, clearly and handsomely printed, and offered at a price which renders it one of the cheapest works ever presented to the American profession.

But not only is the American edition more convenient and lower priced than the English; it is also better and more complete. Some years having elapsed since the appearance of a portion of the work, additions are required to bring up the subjects to the existing condition of science. Some diseases, also, which are comparatively unimportant in England, require more elaborate treatment to adapt the articles devoted to them to the wants of the American physician; and there are points on which the received practice in this country differs from that adopted abroad. The supplying of these deficiencies has been undertaken by HENRY HARTSHORNE, M D., late Professor of Hygiene in the University of Pennsylvania, who has endeavored to render the work fully up to the day, and as useful to the American physician as it has proved to be to his English brethren. The number of illustrations has also been largely increased, and no effort spared to render the typographical execution unexceptionable in every respect.

Really too much praise can scarcely be given to this noble book. It is a cyclopædia of medicine written by some of the best men of Europe. It is full of useful information such as one finds frequent need of in one's daily work As a book of reference it is invaluable. It is up with the times. It is clear and concentrated in style, and its form is worthy of its famous publisher.—*Louisville Med. News*, Jan. 31, 1880.

"Reynolds' System of Medicine" is justly considered the most popular work on the principles and practice of medicine in the English language The contributors to this work are gentlemen of well-known reputation on both sides of the Atlantic. Each gentleman has striven to make his part of the work as practical as possible, and the information contained is such as is needed by the busy practitioner.—*St. Louis Med. and Surg. Journ*, Jan. '80.

Dr. Hartshorne has made ample additions and revisions, all of which give increased value to the volume, and render it more useful to the American practitioner There is no volume in English medical literature more valuable, and every purchaser will, on becoming familiar with it, congratulate himself on the possession of this vast storehouse of information, in regard to so many of the subjects with which he should be familiar.—*Gaillard's Med. Journ*, Feb. 1880.

There is no medical work which we have in times past more frequently and fully consulted when perplexed by doubts as to treatment, or by having unusual or apparently inexplicable symptoms presented to us than "Reynolds' System of Medicine." Among its contributors are gentlemen who are as well known by reputation upon this side of the Atlantic as in Great Britain, and whose right to speak with authority upon the subjects about which they have written, is recognized the world over. They have evidently striven to make their essays as practical as possible, and while these are sufficiently full to entitle them to the name of monographs, they are not loaded down with such an amount of detail as to render them wearisome to the general reader. In a word, they contain just the kind of information which the busy practitioner frequently finds himself in need of. In order that any deficiencies may be supplied, the publishers have committed the preparation of the book for the press to Dr. Henry Hartshorne, whose judicious notes distributed throughout the volume afford abundant evidence of the thoroughness of the revision to which he has subjected it.—*Am. Jour. Med. Sciences*, Jan. 1880.

BARTHOLOW (ROBERTS), A.M., M.D., LL.D.

Prof. of Materia Medica and General Therapeutics in the Jeff Med. Coll. of Phila., etc.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATION TO MEDICINE.

In one very handsome 12mo. volume of about 300 pages, with numerous illustrations. (*In press.*)

The constantly increasing therapeutic use of electricity, and the absence of a concise guide suited to the wants of the general practitioner, have induced the author to prepare the present volume. His object has been to present the most advanced state of existing knowledge in a form divested of unnecessary technicalities, keeping constantly in view the practical needs of the student and physician.

As the volume is founded upon a course of lectures delivered in the Jefferson Medical College during 1880, its adaptation to its purpose is insured. Dr. Bartholow's power of lucid exposition is well known, and is particularly desirable in a subject such as this, treated from the standpoint of the general practitioner and not of the specialist.

FINLAYSON (JAMES), M.D.,

Physician and Lecturer on Clinical Medicine in the Glasgow Western Infirmary, etc.

CLINICAL DIAGNOSIS; A Handbook for Students and Practitioners of Medicine.

In one handsome 12mo. volume, of 546 pages, with 85 illustrations. Cloth, $2 63. (*Just Issued.*)

The book is an excellent one, clear, concise, convenient, practical. It is replete with the very knowledge the student needs when he quits the lecture-room and the laboratory for the ward and sick-room, and does not lack in information that will meet the wants of experienced and older men.—*Phila. Med. Times*, Jan. 4, 1879.

This is one of the really useful books. It is attractive from preface to the final page, and ought to be given a place on every office table, because it contains in a condensed form all that is valuable in semeiology and diagnostics to be found in bulkier volumes, and because in its arrangement and complete index, it is unusually convenient for quick reference in any emergency that may come upon the busy practitioner. —*N. C. Med. Journ.*, Jan. 1879.

MITCHELL (S. WEIR), M.D.,

Phys. to Orthopædic Hospital and the Infirmary for Dis. of the Nervous System, Phila., etc. etc.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, ESPECIALLY IN WOMEN.

In one very handsome 12mo. volume of about 250 pages, with five lithographic plates. (*Shortly.*)

HAMILTON (ALLAN McLANE), M.D.,

Attending Physician at the Hospital for Epileptics and Paralytics, Blackwell's Island, N.Y., and at the Out-Patients' Department of the New York Hospital.

NERVOUS DISEASES; THEIR DESCRIPTION AND TREATMENT.

In one handsome octavo volume of 512 pages, with 53 illus.; cloth, $3 50. (*Lately Issued.*)

CLINICAL OBSERVATIONS ON FUNCTIONAL NERVOUS DISORDERS By C. HANDFIELD JONES, M.D., Physician to St. Mary's Hospital, &c. Second American Edition. In one handsome octavo volume of 348 pages, cloth, $3 25.

MORRIS (MALCOLM), M.D.,

Joint Lecturer on Dermatology, St. Mary's Hospital Med. School.

SKIN DISEASES, Including their Definitions, Symptoms, Diagnosis, Prognosis, Morbid Anatomy, and Treatment.

A Manual for Students and Practitioners. In one 12mo. volume of over 300 pages. With illustrations. Cloth, $1 75. (*Now Ready.*)

To physicians who would like to know something about skin diseases, so that when a patient presents himself for relief they can make a correct diagnosis and prescribe a rational treatment, we unhesitatingly recommend this little book of Dr. Morris. The affections of the skin are described in a terse, lucid manner, and their several characteristics so plainly set forth that diagnosis will be easy. The treatment in each case is such as the experience of the most eminent dermatologists advise.—*Cincinnati Medical News*, April, 1880.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that in the whole range of medical literature of a like scope, there is no book which for clearness of expression, and methodical arrangement is better adapted to promote a rational conception of dermatology, a branch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine*, April, 1880.

The author of this manual has evidently a full and intimate acquaintance with the literature of dermatology, and with the most recent developments and appliances of cutaneous medicine. He has produced a plain, practical book, by aid of which, who so chooses may train his eye to the recognition of light but significant differences. The descriptions are neither too vague nor over-refined; the directions for treatment are clear and succinct.—*London Brain*, April, 1880.

The author has handled his subject in a clear and concise manner, and as a text-book to students his manual will be found useful.—*Medical and Surgical Reporter*, March 27, 1880.

The author's task has been well done and has produced one of the best recent works upon the difficult subject of which it treats; there is no work published which gives a better view of the elementary facts and principles of dermatology.—*New Orleans Medical and Surgical Journal*, April, 1880.

This excellent little book is the first work of a distinguished pupil of Jonathan Hutchinson; it recommends itself above all by its clearness, method, and precision.—*Annales de Dermatologie et de Syphiligraphie, Paris*, 25 April, 1880.

FOX (TILBURY), M.D., F.R.C.P., and T. C. FOX, B.A., M.R.C.S.,

Physician to the Department for Skin Diseases, University College Hospital.

EPITOME OF SKIN DISEASES. WITH FORMULÆ. FOR STUDENTS AND PRACTITIONERS.

Second edition, thoroughly revised and greatly enlarged. In one very handsome 12mo. volume of 216 pages. Cloth, $1 38. (*Just Issued.*)

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Hospital Med. College, N. Y.

A MANUAL OF PERCUSSION AND AUSCULTATION; of the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism. Second edition. In one handsome royal 12mo. volume: cloth, $1 63. (*Just Ready.*)

Prof. Flint is so well known as a medical teacher and writer that it seems superfluous to state that the subject has been treated in a thorough and systematic manner. In revising it for a second edition the author has confined himself to such additions as seem likely to render it more useful, not only to students engaged in the practical study of the subject, but also to practitioners as a handbook for ready reference, and we do not hesitate in saying that it would prove a valuable addition to every physician's library.—*Med. and Surg. Reporter*, March 18, 1880.

The little work before us has already become a standard one, and has become extensively adopted as a text-book. There is certainly none better. It contains the substance of the lessons which the author has for many years given, in connection with practical instruction in auscultation and percussion, to private classes, composed of medical students and practitioners.—*Cincinnati Med. News*, Feb. 1880.

BY THE SAME AUTHOR.

PHTHISIS: ITS MORBID ANATOMY, ETIOLOGY, SYMPTOMATIC EVENTS AND COMPLICATIONS, FATALITY AND PROGNOSIS, TREATMENT AND PHYSICAL DIAGNOSIS; in a series of Clinical Studies. By AUSTIN FLINT, M.D., Prof. of the Principles and Practice of Medicine in Bellevue Hospital Med. College, New York. In one handsome octavo volume: $3 50. (*Lately Issued.*)

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DIAGNOSIS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART. Second revised and enlarged edition. In one octavo volume of 550 pages, with a plate, cloth, $4.

Dr. Flint chose a difficul' subject for his researches, and has shown remarkable powers of observation and reflection, as well as great industry, in his treatment of it. His book must be considered the fullest and clearest practical treatise on those subjects, and should be in the hands of all practitioners and students. It is a credit to American medical literature. —*Amer. Journ. of the Med. Sciences*, July, 1860.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE PHYSICAL EXPLORATION OF THE CHEST AND THE DIAGNOSIS OF DISEASES AFFECTING THE RESPIRATORY ORGANS. Second and revised edition. In one handsome octavo volume of 595 pages, cloth, $4 50.

BROWN (LENNOX), F.R.C.S. Ed.,

Senior Surgeon to the Central London Throat and Ear Hospital, etc.

THE THROAT AND ITS DISEASES. With one hundred Typical Illustrations in colors, and fifty wood engravings, designed and executed by the author. In one very handsome imperial octavo volume of 351 pages; cloth, $5 00. (*Just Ready.*)

SEILER (CARL), M.D.,

Lecturer on Laryngoscopy at the Univ. of Penna, Chief of the Throat Dispensary at the Univ. Hospital, Phila., etc.

HANDBOOK OF DIAGNOSIS AND TREATMENT OF DISEASES OF THE THROAT AND NASAL CAVITIES. In one handsome royal 12mo. volume, of 156 pages, with 35 illustrations; cloth, $1. (*Just Ready.*)

We most heartily commend this book as showing sound judgment in practice, and perfect familiarity with the literature of the specialty it so ably epitomizes.— *Philada. Med. Times*, July 5, 1879.

A convenient little handbook, clear, concise, and accurate in its method, and admirably fulfilling its purpose of bringing the subject of which it treats within the comprehension of the general practitioner.—*N. C. Med. Jour.*, June, 1879.

WILLIAMS'S PULMONARY CONSUMPTION; its Nature, Varieties, and Treatment. With an Analysis of One Thousand Cases to exemplify its duration. In one neat octavo volume of about 350 pages; cloth, $2 50.

SLADE ON DIPHTHERIA; its Nature and Treatment, with an account of the History of its Prevalence in various Countries. Second and revised edition. In one neat royal 12mo. volume, cloth, $1 25.

WALSHE ON THE DISEASES OF THE HEART AND GREAT VESSELS. Third American Edition. In 1 vol. 8vo., 420 pp., cloth, $3 00.

CHAMBERS'S MANUAL OF DIET AND REGIMEN IN HEALTH AND SICKNESS. In one handsome octavo volume. Cloth, $2 75.

LA ROCHE ON PNEUMONIA. 1 vol. 8vo., cloth, of 500 pages. Price, $3 00.

WILSON'S STUDENT'S BOOK OF CUTANEOUS MEDICINE and DISEASES OF THE SKIN. In one very handsome royal 12mo. volume. $3 50.

FULLER ON DISEASES OF THE LUNGS AND AIR-PASSAGES. Their Pathology, Physical Diagnosis, Symptoms, and Treatment. From the second and revised English edition. In one handsome octavo volume of about 500 pages: cloth, $3 50.

SMITH ON CONSUMPTION; ITS EARLY AND REMEDIABLE STAGES. 1 vol. 8vo., pp. 254. $2 25.

BASHAM ON RENAL DISEASES: a Clinical Guide to their Diagnosis and Treatment. With Illustrations. In one 12mo. vol. of 304 pages, cloth, $2 00.

LECTURES ON THE STUDY OF FEVER. By A. HUDSON, M.D., M.R.I.A., Physician to the Meath Hospital. In one vol. 8vo., cloth, $2 50.

A TREATISE ON FEVER. By ROBERT D. LYONS, K.C.C. In one octavo volume of 362 pages, cloth $2 25.

HILLIER'S HANDBOOK OF SKIN DISEASES, for Students and Practitioners. Second Am Ed. In one royal 12mo. vol. of 358 pp. With illustrations. Cloth, $2 25.

BUMSTEAD (FREEMAN J.), M.D., LL.D.,

Professor of Venereal Diseases at the Col. of Phys and Surg., New York, &c.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES.

Including the results of recent investigations upon the subject. Fourth edition, revised and largely rewritten with the co-operation of R. W. Taylor, M.D., of New York, Prof. of Dermatology in the Univ. of Vt. In one large and handsome octavo volume of 835 pages, with 138 illustrations. Cloth, $4 75; leather, $5 75; half Russia, $6 25. (*Now Ready.*)

This work, on its first appearance, immediately took the position of a standard authority on its subject wherever the language is spoken, and the success of an Italian translation shows that it is regarded with equal favor on the Continent of Europe. In repeated editions the author labored sedulously to render it more worthy of its reputation, and in the present revision no pains have been spared to perfect it as far as possible. Several years having elapsed since the publication of the third edition, much material has been accumulated during the interval by the industry of syphilologists, and new views have been enunciated. All this so far as confirmed by observation and experience, has been incorporated; many portions of the volume been rewritten, the series of illustrations has been enlarged and improved, and the whole may be regarded rather as a new work than as a new edition. It is confidently presented as fully on a level with the most advanced condition of syphilology, and as a work to which the practitioner may refer with the certainty of finding clearly and succinctly set forth whatever falls within the scope of such a treatise.

We have to congratulate our countrymen upon the truly valuable addition which they have made to American literature. The careful estimate of the value of the volume, which we have made, justifies us in declaring that this is the best treatise on venereal diseases in the English language, and, we might add, if there is a better in any other tongue we cannot name it; there are certainly no books in which the student or the general practitioner can find such an excellent *résumé* of the literature of any topic, and such practical suggestions regarding the treatment of the various complications of every venereal disease. We take pleasure in repeating that we believe this to be the best treatise on venereal disease in the English language, and we congratulate the authors upon their brilliant addition to American medical literature.—*Chicago Med. Journal and Examiner*, February, 1880.

It is, without exception, the most valuable single work on all branches of the subject of which it treats in any language. The pathology is sound, the work is, at the same time, in the highest degree practical, and the hints that he will get from it for the management of any one case, at all obscure or obstinate, will more than repay him for the outlay.—*Archives of Medicine*, April, 1880.

This now classical work on venereal disease comes to us in its fourth edition rewritten, enlarged, and materially improved in every way. Dr Taylor, as we had every reason to expect, has performed this part of his work with unusual excellence. We feel that what has been written has done but scanty justice to the merits of this truly great treatise.—*St. Louis Courier of Medicine*, Feb. 1880

We find that we have here practically a new book—that the statement of the title page, as to the fact that it has been largely rewritten, is a sufficiently modest announcement for the important changes in the text. After a thorough examination of the present edition, we can assert confidently that the enormous labor we have described has been here most faithfully and conscientiously performed.—*Amer. Journ. Med. Sci.*, Jan 1880.

It is one of the best general treatises on venereal diseases with which we are acquainted, and is especially to be recommended as a guide to the treatment of syphilis.—*London Practitioner*, March, 1880.

CULLERIER (A.), Surgeon to the Hôpital du Midi. and BUMSTEAD (FREEMAN J.), Professor of Venereal Diseases in the College of Physicians and Surgeons, N Y

AN ATLAS OF VENEREAL DISEASES.

Translated and Edited by FREEMAN J. BUMSTEAD. In one large imperial 4to. volume of 328 pages, double-columns, with 26 plates, containing about 150 figures, beautifully colored, many of them the size of life; strongly bound in cloth, $17 00; also, in five parts, stout wrappers, at $3 per part.

Anticipating a very large sale for this work, it is offered at the very low price of THREE DOLLARS a Part, thus placing it within the reach of all who are interested in this department of practice. Gentlemen desiring early impressions of the plates would do well to order it without delay. A specimen of the plates and text sent free by mail, on receipt of 25 cents.

LEE'S LECTURES ON SYPHILIS AND SOME FORMS OF LOCAL DISEASE AFFECTING PRINCIPALLY THE ORGANS OF GENERATION. In one handsome octavo volume; cloth, $2 25.

HILL ON SYPHILIS AND LOCAL CONTAGIOUS DISORDERS. In one handsome octavo volume; cloth $3 25.

WEST (CHARLES), M.D.,

Physician to the Hospital for Sick Children, London, &c.

LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD.

Fifth American from the sixth revised and enlarged English edition. In one large and handsome octavo volume of 678 pages. Cloth, $4 50; leather, $5 50. (*Lately Issued.*)

BY THE SAME AUTHOR. (*Lately Issued.*)

ON SOME DISORDERS OF THE NERVOUS SYSTEM IN CHILDHOOD;

being the Lumleian Lectures delivered at the Royal College of Physicians of London, in March, 1871. In one volume small 12mo., cloth, $1 00.

BY THE SAME AUTHOR.

LECTURES ON THE DISEASES OF WOMEN.

Third American, from the Third London edition. In one neat octavo volume of about 550 pages, cloth, $3 75; leather, $4 75.

SMITH (*J. LEWIS*), *M.D.*,

Clinical Professor of Diseases of Children in the Bellevue Hospital Med. College, N.Y.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN.

Fourth Edition, revised and enlarged. In one handsome octavo volume of about 750 pages, with illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

The very marked favor with which this work has been received wherever the English language is spoken, has stimulated the author, in the preparation of the Fourth Edition, to spare no pains in the endeavor to render it worthy in every respect of a continuance of professional confidence. Many portions of the volume have been rewritten, and much new matter introduced, but by an earnest effort at condensation, the size of the work has not been materially increased.

In the period which has elapsed since the third edition of the work, so extensive have been the advances that whole chapters required to be rewritten, and hardly a page could pass without some material correction or addition. This labor has occupied the writer closely, and he has performed it conscientiously, so that the book may be considered a faithful portraiture of an exceptionally wide clinical experience in infantile diseases, corrected by a careful study of the recent literature of the subject.—*Med. and Surg. Reporter*, April 5, 1879.

It is scarcely necessary for us to say the work before us is a standard work upon diseases of children, and that no work has a higher standing than it upon those affections. In consequence of its thorough revision, the work has been made of more value than ever, and may be regarded as fully abreast of the times. We cordially commend it to students and physicians. There is no better work in the language on diseases of children.—*Cincinnati Med. News*, March, 1879.

The author has evidently determined that it shall not lose ground in the esteem of the profession for want of the latest knowledge on that important department of medicine. He has accordingly incorporated in the present edition the useful and practical results of the latest study and experience, both American and foreign, especially those bearing on therapeutics. Altogether the book has been greatly improved, while it has not been greatly increased in size.—*New York Medical Journal*, June, 1879.

This excellent work is so well known that an extended notice at this time would be superfluous. The author has taken advantage of the demand for another new edition to revise in a most careful manner the entire book; and the numerous corrections and additions evince a determination on his part to keep fully abreast with the rapid progress that is being made in the knowledge and treatment of children's diseases. By the adoption of a somewhat closer type, an increase in size of only thirty pages has been necessitated by the new subject matter introduced.—*Boston Med. and Surg. Jour.*, May 29, 1879.

Probably no other work ever published in this country upon a medical subject has reached such a height of popularity as has this well-known treatise. As a text and reference-book it is pre-eminently the authority upon diseases of children. It stands deservedly higher in the estimation of the profession than any other work upon the same subject.—*Nashville Journ. of Med. and Surg.*, May, 1879.

SWAYNE (*JOSEPH GRIFFITHS*), *M.D.*,

Physician-Accoucheur to the British General Hospital, &c.

OBSTETRIC APHORISMS FOR THE USE OF STUDENTS COMMENCING MIDWIFERY PRACTICE.

Second American, from the Fifth and Revised London Edition, with Additions by E. R. HUTCHINS, M.D. With Illustrations. In one neat 12mo. volume. Cloth, $1 25. (*Lately Issued.*)

*** See p. 3 of this Catalogue for the terms on which this work is offered as a premium to subscribers to the AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

CHURCHILL ON THE PUERPERAL FEVER AND OTHER DISEASES PECULIAR TO WOMEN. 1 vol. 8vo., pp. 450, cloth. $2 50.

DEWEES'S TREATISE ON THE DISEASES OF FEMALES. With Illustrations. Eleventh Edition, with the Author's last improvements and corrections. In one octavo volume of 536 pages, with plates, cloth. $3 00.

MEIGS ON THE NATURE, SIGNS, AND TREATMENT OF CHILDBED FEVER. 1 vol. 8vo., pp. 365, cloth. $2 00.

ASHWELL'S PRACTICAL TREATISE ON THE DISEASES PECULIAR TO WOMEN. Third American, from the Third and revised London edition. 1 vol. 8vo., pp. 528, cloth. $3 50.

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Obstetrics, &c., in the University of Pennsylvania.

ON DISEASES PECULIAR TO WOMEN; including Displacements of the Uterus.

With original illustrations. Second edition, revised and enlarged. In one beautifully printed octavo volume of 531 pages, cloth, $4 50.

CHURCHILL (*FLEETWOOD*), *M.D., M.R.I.A.*

ON THE THEORY AND PRACTICE OF MIDWIFERY.

A new American from the fourth revised and enlarged London edition. With notes and additions by D. FRANCIS CONDIE, M.D., author of a Practical Treatise on the Diseases of Children, &c. With one hundred and ninety-four illustrations. In one very handsome octavo volume of nearly 700 large pages. Cloth, $4 00; leather, $5 00.

MONTGOMERY'S EXPOSITION OF THE SIGNS AND SYMPTOMS OF PREGNANCY. With two exquisite colored plates, and numerous wood-cuts. In 1 vol. 8vo., of nearly 600 pp., cloth, $3 75.

CONDIE'S PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Sixth edition, revised and augmented. In one large octavo volume of nearly 800 closely-printed pages, cloth, $5 25; leather $6 25.

RIGBY'S SYSTEM OF MIDWIFERY. With notes and Additional Illustrations. Second American edition. One volume octavo, cloth, 422 pages, $2 50.

SMITH'S PRACTICAL TREATISE ON THE WASTING DISEASES OF INFANCY AND CHILDHOOD. Second American, from the second revised and enlarged English edition. In one handsome octavo volume, cloth, $2 50.

THOMAS (T. GAILLARD), M.D.,

Professor of Obstetrics, &c., in the College of Physicians and Surgeons, N. Y., &c.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN.

Fifth edition, thoroughly revised and rewritten. In one large and handsome octavo volume of over 800 pages, with 266 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50. (*Just Ready.*)

The author has taken advantage of the opportunity afforded by the call for a new edition of this work to render it worthy a continuance of the very remarkable favor with which it has been received. Every portion of the work has been carefully revised, very much of it has been rewritten, and additions and alterations introduced wherever the advance of science and the increased experience of the author have shown them desirable. At the same time special care has been exercised to avoid undue increase in the size of the volume. To accommodate the numerous additions a more condensed but very clear letter has been used, notwithstanding which, the number of pages has been increased by more than fifty. The series of illustrations has been extensively changed; many which seemed to be superfluous have been omitted, and a large number of new and superior drawings have been inserted. In its improved form, therefore, it is hoped that the volume will maintain the character it has acquired of a standard authority on every detail of its important subject.

An examination of the work will satisfy that it is one of great merit. It is not a mere compilation from other works, but is the fruit of the ripe thought, sound judgment, and critical observations of a learned, scientific man. It is a treasury of knowledge of the department of medicine to which it is devoted. In its present revised state it certainly holds a foremost position as a gynæcological work, and will continue to be regarded as a standard authority.—*Cincinnati Med. News*, Dec. 1880.

This work needs no introduction to any of the civilized nations of the world. The edition before us adds to the strength of former volumes. With the wisdom of a master teacher he here gives the results that, in his judgment, are most trustworthy at the present time. In its own place it has no rival, because the author is the best teacher on this subject to the masses of the profession. As hitherto this work will be the text-book on diseases of women. We only wish that in other branches of medicine as capable teachers could be found to write our text-books.—*Detroit Lancet*, Jan. 1881.

Since its first appearance, twelve years ago, until the present day, it has held a position of high regard, and is generally conceded to be one of the most practical and trustworthy volumes yet presented to the physician and student in the department of gynæcology. The work embodies not only its author's large experience, but reflects his careful study among other authorities in this branch, both at home and abroad. Dr. Thomas is an able and conscientious teacher. His writings convey his meaning in the same practical and instructive manner. The last edition of this work is fresh from his pen, with decided changes and improvements over former editions. His book presents generally accepted facts, and as a guide to the student is more useful and reliable than any work in the language on diseases of women. This last edition will add new laurels to those already won.—*Md. Med. Journ.*, Nov. 15, 1880.

It has been enlarged and carefully revised. The author has brought it fully abreast with the times, and as the wave of gynæcological progression has been widespread and rapid during the twelve years that have elapsed since the issue of the first edition, one can conceive of the great improvement this edition must be upon the earlier. It is a condensed encyclopædia of gynæcological medicine. The style of arrangement, the masterly manner in which each subject is treated, and the honest convictions derived from probably the largest clinical experience in that specialty of any in this country, all serve to commend it in the highest terms to the practitioner. —*Nashville Journ. of Med. and Surg.*, Jan. 1881.

BARNES (ROBERT), M.D., F.R.C.P.,

Obstetric Physician to St. Thomas's Hospital, &c.

A CLINICAL EXPOSITION OF THE MEDICAL AND SURGICAL DISEASES OF WOMEN.

Second American, from the Second Enlarged and Revised English Edition. In one handsome octavo volume, of 784 pages, with 181 illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Issued.*)

Dr Barnes stands at the head of his profession in the old country, and it requires but scant scrutiny of his book to show that it has been sketched by a master. It is plain, practical common sense; shows very deep research without being pedantic; is eminently calculated to inspire enthusiasm without inculcating rashness; points out the dangers to be avoided as well as the success to be achieved in the various operations connected with this branch of medicine; and will do much to smooth the rugged path of the young gynæcologist and relieve the perplexity of the man of mature years.—*Canadian Journ. of Med. Science*, Nov. 1878.

We pity the doctor who, having any considerable practice in diseases of women, has no copy of "Barnes" for daily consultation and instruction. It is at once a book of great learning, research, and individual experience, and at the same time eminently practical. That it has been appreciated by the profession, both in Great Britain and in this country, is shown by the second edition following so soon upon the first.—*Am. Practitioner*, Nov. 1878.

Dr. Barnes's work is one of a practical character, largely illustrated from cases in his own experience, but by no means confined to such, as will be learned from the fact that he quotes from no less than 628 medical authors in numerous countries. Coming from such an author, it is not necessary to say that the work is a valuable one, and should be largely consulted by the profession.—*Am. Supp. Obstetrical Journ. Gt. Britain and Ireland*, Oct. 1878.

No other gynæcological work holds a higher position, having become an authority everywhere in diseases of women. The work has been brought fully abreast of present knowledge. Every practitioner of medicine should have it upon the shelves of his library, and the student will find it a superior text-book.—*Cincinnati Med. News*, Oct. 1878.

This second revised edition, of course, deserves all the commendation given to its predecessor, with the additional one that it appears to include all or nearly all the additions to our knowledge of its subject that have been made since the appearance of the first edition. The American references are, for an English work, especially full and appreciative, and we can cordially recommend the volume to American readers.—*Journ. of Nervous and Mental Disease*, Oct. 1878.

This second edition of Dr. Barnes's great work comes to us containing many additions and improvements which bring it up to date in every feature. The excellences of the work are too well known to require enumeration, and we hazard the prophesy that they will for many years maintain its high position as a standard text-book and guide-book for students and practitioners.—*N. C. Med. Journ.*, Oct. 1878.

EMMET (*THOMAS ADDIS*), *M.D.*,

Surgeon to the Woman's Hospital, New York, etc.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the use of Students and Practitioners of Medicine. Second Edition. Thoroughly Revised. In one large and very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

PREFACE TO THE SECOND EDITION.

The unusually rapid exhaustion of a large edition of this work, while flattering to the author as an evidence that his labors have proved acceptable, has in a great measure heightened his sense of responsibility. He has therefore endeavored to take full advantage of the opportunity afforded to him for its revision. Every page has received his earnest scrutiny; the criticisms of his reviewers have been carefully weighed; and while no marked increase has been made in the size of the volume, several portions have been rewritten, and much new matter has been added. In this minute and thorough revision, the labor involved has been much greater than is perhaps apparent in the results, but it has been cheerfully expended in the hope of rendering the work more worthy of the favor which has been accorded to it by the profession.

In no country of the world has gynæcology received more attention than in America. It is, then, with a feeling of pleasure that we welcome a work on diseases of women from so eminent a gynæcologist as Dr. Emmet, and the work is essentially clinical, and leaves a strong impress of the author's individuality. To criticise, with the care it merits, the book throughout, would demand far more space than is at our command. In parting, we can say that the work teems with original ideas, fresh and valuable methods of practice, and is written in a clear and elegant style, worthy of the literary reputation of the country of Longfellow and Oliver Wendell Holmes.—*Brit. Med. Journ.* Feb. 21, 1880.

No gynæcological treatise has appeared which contains an equal amount of original and useful matter; nor does the medical and surgical history of America include a book more novel and useful. The tabular and statistical information which it contains is marvellous, both in quantity and accuracy, and cannot be otherwise than invaluable to future investigators. It is a work which demands not careless reading but profound study. Its value as a contribution to gynæcology is, perhaps, greater than that of all previous literature on the subject combined.—*Chicago Med Gaz.*, April 5, 1880

The wide reputation of the author makes its publication an event in the gynæcological world; and a glance through its pages shows that it is a work to be studied with care. . . . It must always be a work to be carefully studied and frequently consulted by those who practise this branch of our profession.—*Lond. Med. Times and Gaz.*, Jan. 10, 1880.

The character of the work is too well known to require extended notice—suffice it to say that no recent work upon any subject has attained such great popularity so rapidly. As a work of general reference upon the subject of Diseases of Women it is invaluable. As a record of the largest clinical experience and observation it has no equal. No physician who pretends to keep up with the advances of this department of medicine can afford to be without it.—*Nashville Journ. of Medicine and Surgery*, May, 1880.

DUNCAN (*J. MATTHEWS*), *M.D., LL.D., F.R.S.E., etc.*

CLINICAL LECTURES ON THE DISEASES OF WOMEN, Delivered in Saint Bartholomew's Hospital. In one very neat octavo volume of 173 pages. Cloth, $1 50. (*Just Ready.*)

They are in every way worthy of their author; indeed, we look upon them as among the most valuable of his contributions. They are all upon matters of great interest to the general practitioner. Some of them deal with subjects that are not, as a rule, adequately handled in the text-books; others of them, while bearing upon topics that are usually treated of at length in such works, yet bear such a stamp of individuality that, if widely read, as they certainly deserve to be, they cannot fail to exert a wholesome restraint upon the undue eagerness with which many young physicians seem bent upon following the wild teachings which so infest the gynæcology of the present day.—*N. Y. Med. Journ.*, March, 1880.

The author is a remarkably clear lecturer, and his discussion of symptoms and treatment is full and suggestive. It will be a work which will not fail to be read with benefit by practitioners as well as by students.—*Phila. Med. and Surg. Reporter*, Feb. 7, 1880.

We have read this book with a great deal of pleasure. It is full of good things. The hints on pathology and treatment scattered through the book are sound, trustworthy, and of great value. A healthy scepticism, a large experience, and a clear judgment are everywhere manifest. Instead of bristling with advice of doubtful value and unsound character, the book is in every respect a safe guide.—*The London Lancet*, Jan. 21, 1880.

RAMSBOTHAM (*FRANCIS H.*), *M.D.*

THE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY; in reference to the Process of Parturition. A new and enlarged edition, thoroughly revised by the author. With additions by W. V. KEATING, M. D., Professor of Obstetrics, &c., in the Jefferson Medical College, Philadelphia. In one large and handsome imperial octavo volume of 650 pages, strongly bound in leather, with raised bands; with sixty-four beautiful plates, and numerous wood-cuts in the text, containing in all nearly 200 large and beautiful figures. $7 00.

WINCKEL (*F.*),

Professor and Director of the Gynæcological Clinic in the University of Rostock.

A COMPLETE TREATISE ON THE PATHOLOGY AND TREATMENT OF CHILDBED, for Students and Practitioners. Translated, with the consent of the author, from the Second German Edition, by JAMES READ CHADWICK, M.D. In one octavo volume. Cloth, $4 00. (*Lately Issued.*)

TANNER (*THOMAS H.*), *M.D.*

ON THE SIGNS AND DISEASES OF PREGNANCY. First American from the Second and Enlarged English Edition. With four colored plates and illustrations on wood. In one handsome octavo volume of about 500 pages, cloth, $4 25.

LEISHMAN (*WILLIAM*), *M.D.*,

Regius Professor of Midwifery in the University of Glasgow, &c.

A SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE.

Third American edition, revised by the Author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Philadelphia Hospital, &c. In one large and very handsome octavo volume, of 733 pages, with over two hundred illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready.*)

Few works on this subject have met with as great a demand as this one appears to have. To judge by the frequency with which its author's views are quoted, and its statements referred to in obstetrical literature, one would judge that there are few physicians devoting much attention to obstetrics who are without it. The author is evidently a man of ripe experience and conservative views, and in no branch of medicine are these more valuable than in this.—*New Remedies*, Jan. 1880.

We gladly welcome the new edition of this excellent text book of midwifery. The former editions have been most favorably received by the profession on both sides of the Atlantic. In the preparation of the present edition the author has made such alterations as the progress of obstetrical science seems to require, and we cannot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

To the American student the work before us must prove admirably adapted, complete in all its parts, essentially modern in its teachings and with demonstrations noted for clearness and precision, it will gain in favor and be recognized as a work of standard merit. The work cannot fail to be popular, and is cordially recommended.—*N. O. Med. and Surg. Journ.*, March, 1880.

Leishman's is certainly one of the best systematic works on midwifery. It is very complete in all the parts essential for such a treatise. To practitioners and students it is to be strongly recommended as a safe and reliable guide to the modern practice of midwifery.—*Canada Med. and Surg. Journal*, March, 1880.

This is a book of well-established reputation, both in England and America. The present edition has been revised with care by the distinguished author, and supplied with such additions and emendations as the rapid advances in obstetrical science demand. *Pacific Med. and Surg. Journ.*, May, 1880.

The book is greatly improved, and as such will be welcomed by those who are trying to keep posted in the rapid advances which are being made in the study of obstetrics.—*Boston Med and Surg. Journ.*, Nov 27, 1879.

This work is a thoroughly good one, and is well adapted to the requirements of the practical obstetrician. It is something more than a compend designed for the medical student: it is a book to be studied by the practitioner, and it will seldom disappoint him. It is of convenient size, clearly written, and eminently practical. As such, we heartily commend it to our readers.—*St. Louis Clin. Record*, Jan. 1880.

We are glad to call the attention of our readers to this new edition of Dr. Leishman's well-known work which has already established itself in general favor both in this country and in America. In noticing this third edition we need only direct attention to the differences between it and its predecessor. Although carefully revised throughout, with not a few additions in various places, the net enlargement amounts only to a few pages.—*Glasgow Med. Journ.*, Jan. 1880.

Leishman's is certainly one of the best systematic works on midwifery. It is very complete in all the parts essential for such a treatise. To practitioners and students it is to be strongly recommended as a safe and reliable guide to the modern practice of midwifery.—*Canada Med. and Surg. Journal*, March, 1880.

It has been well and carefully written. The views of the author are broad and liberal, and indicate a well balanced judgment and matured mind. We observe no spirit of dogmatism, but the earnest teaching of the thoughtful observer and lover of true science. Take the volume as a whole, and it has few equals.—*Md. Med. Journ.*, Feb. 1880.

Dr Leishman is too well known to the profession, not only that but to the student who is about to enter the profession, to need any introduction. Of his work, we need but say that it is a standard, sound and practical.—*St. Louis Courier of Med.*, Jan. 1880.

PARRY (*JOHN S.*), *M.D.*,

Obstetrician to the Philadelphia Hospital, Vice-Pres. of the Obstet. Society of Philadelphia.

EXTRA-UTERINE PREGNANCY: ITS CLINICAL HISTORY, DIAGNOSIS, PROGNOSIS, AND TREATMENT.

In one handsome octavo volume. Cloth, $2 50. (*Lately Issued.*)

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Midwifery, &c., in the University of Pennsylvania, &c.

THE PRINCIPLES AND PRACTICE OF OBSTETRICS.

Illustrated with large lithographic plates containing one hundred and fifty-nine figures from original photographs, and with numerous wood-cuts. In one large and beautifully printed quarto volume of 550 double-columned pages, strongly bound in cloth, $14.

The work of Dr. Hodge is something more than a simple presentation of his particular views in the department of Obstetrics; it is something more than an ordinary treatise on midwifery; it is, in fact, a cyclopædia of midwifery. He has aimed to embody in a single volume the whole science and art of Obstetrics. An elaborate text is combined with accurate and varied pictorial illustrations so that no fact or principle is left unstated or unexplained. —*Am. Med. Times*, Sept. 3, 1864.

*** Specimens of the plates and letter-press will be forwarded to any address, free by mail on receipt of six cents in postage stamps.

CHADWICK (*JAMES R.*), *A.M.*, *M.D.*

A MANUAL OF THE DISEASES PECULIAR TO WOMEN.

In one neat volume, royal 12mo., with illustrations. (*Preparing.*)

PLAYFAIR (*W. S.*), *M.D., F.R.C.P.*,

Professor of Obstetric Medicine in King's College, etc. etc.

A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY.

Third American edition, revised by the author. Edited, with additions, by ROBERT P. HARRIS, M D. In one handsome octavo volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, $5 50. (*Just Ready*)

EXTRACT FROM THE AUTHOR'S PREFACE.

The second American edition of my work on Midwifery being exhausted before the corresponding English edition, I cannot better show my appreciation of the kind reception my book has received in the United States than by acceding to the publisher's request that I should myself undertake the issue of a third edition. As little more than a year has elapsed since the second edition was issued, there are naturally not many changes to make, but I have, nevertheless, subjected the entire work to careful revision, and introduced into it a notice of most of the more important recent additions to obstetric science. To the operation of gastro-elytrotomy—formerly described along with the Cæsarean section—I have now devoted a separate chapter. The editor of the Second American edition, Dr. Harris, enriched it with many valuable notes, of which, it will be observed, I have freely availed myself.

The medical profession has now the opportunity of adding to their stock of standard medical works one of the best volumes on midwifery ever published. The subject is taken up with a master hand. The part devoted to labor in all its various presentations, the management and results, is admirably arranged, and the views entertained will be found essentially modern, and the opinions expressed trustworthy The work abounds with plates, illustrating various obstetrical positions; they are admirably wrought, and afford great assistance to the student.—*N. O. Med. and Surg. Journ.*, March, 1880.

If inquired of by a medical student what work on obstetrics we should recommend for him, as *par excellence*, we would undoubtedly advise him to choose Playfair's. It is of convenient size, but what is of chief importance, its treatment of the various subjects is concise and plain. While the discussions and descriptions are sufficiently elaborate to render a very intelligent idea of them, yet all details not necessary for a full understanding of the subject are omitted.—*Cincinnati Med. News*, Jan. 1880.

The rapidity with which one edition of this work follows another is proof alike of its excellence and of the estimate that the profession has formed of it. It is indeed so well known and so highly valued that nothing need be said of it as a whole. All things considered, we regard this treatise as the very best on Midwifery in the English language.—*N. Y. Medical Journal*, May, 1880

It certainly is an admirable exposition of the Science and Practice of Midwifery. Of course the additions made by the American editor, Dr. R. P. Harris, who never utters an idle word, and whose studious researches in some special departments of obstetrics are so well known to the profession, are of great value.—*The American Practitioner*, April, 1880.

BARNES (*FANCOURT*), *M.D.*,

Physician to the General Lying-in Hospital, London.

A MANUAL OF MIDWIFERY FOR MIDWIVES AND MEDICAL STUDENTS.

With 50 illustrations. In one neat royal 12mo. volume of 200 pages; cloth, $1 25. (*Now Ready.*)

The book is written in plain, and as far as possible in untechnical language. Any intelligent midwife or medical student can easily comprehend the directions. It will undoubtedly fill a want, and will be popular with those for whom it has been prepared. The examining questions at the back will be found very useful.—*Cincinnati Med. News*, Aug. 1879.

STIMSON (*LEWIS A.*), *A.M., M.D.*,

Surgeon to the Presbyterian Hospital.

A MANUAL OF OPERATIVE SURGERY.

In one very handsome royal 12mo. volume of about 500 pages, with 332 illustrations; cloth, $2 50. (*Just Issued.*)

The work before us is a well printed, profusely illustrated manual of over four hundred and seventy pages. The novice, by a perusal of the work, will gain a good idea of the general domain of operative surgery, while the practical surgeon has presented to him within a very concise and intelligible form the latest and most approved selections of operative procedure. The precision and conciseness with which the different operations are described enable the author to compress an immense amount of practical information in a very small compass.—*N. Y. Medical Record*, Aug. 3, 1878.

This volume is devoted entirely to operative surgery, and is intended to familiarize the student with the details of operations and the different modes of performing them. The work is handsomely illustrated, and the descriptions are clear and well drawn. It is a clever and useful volume; every student should possess one. The preparation of this work does away with the necessity of pondering over larger works on surgery for descriptions of operations, as it presents in a nut-shell just what is wanted by the surgeon without an elaborate search to find it.—*Md. Med Journal*, Aug. 1878.

The author's conciseness and the repleteness of the work with valuable illustrations entitle it to be classed with the text-books for students of operative surgery, and as one of reference to the practitioner. —*Cincinnati Lancet and Clinic*, July 27, 1878.

SMEY'S OPERATIVE SURGERY. In 1 vol. 8vo. cl., of 650 pages; with about 100 wood-cuts. $3 25

COOPER'S LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY. In 1 vol. 8vo. cl'h, 750 p. $2.

GIBSON'S INSTITUTES AND PRACTICE OF SURGERY. Eighth edit'n, improved and altered. With thirty-four plates. In two handsome octavo volumes, about 1000 pp., leather, raised bands. $6 50.

THE PRINCIPLES AND PRACTICE OF SURGERY. By WILLIAM PIRRIE, F.R S.E., Profes'r of Surgery in the University of Aberdeen. Edited by JOHN NEILL, M.D., Professor of Surgery in the Penna. Medical College, Surg'n to the Pennsylvania Hospital, &c. In one very handsome octavo vol. of 780 pages, with 316 illustrations, cloth, $3 75.

MILLER'S PRINCIPLES OF SURGERY. Fourth American, from the Third Edinburgh Edition. In one large 8vo. vol. of 700 pages, with 340 illustrations, cloth, $3 75.

MILLER'S PRACTICE OF SURGERY. Fourth American, from the last Edinburgh Edition Revised by the American editor. In one large 8vo. vol. of nearly 700 pages, with 364 illustrations: cloth, $3 75.

GROSS (SAMUEL D.), M.D.,

Professor of Surgery in the Jefferson Medical College of Philadelphia.

SYSTEM OF SURGERY: Pathological, Diagnostic, Therapeutic, and Operative.

Illustrated by upwards of Fourteen Hundred Engravings. Fifth edition, carefully revised and improved. In two large and beautifully printed imperial octavo volumes of about 2300 pp., strongly bound in leather, with raised bands, $15; half Russia, raised bands, $16.

The continued favor, shown by the exhaustion of successive large editions of this great work, proves that it has successfully supplied a want felt by American practitioners and students. In the present revision no pains have been spared by the author to bring it in every respect fully up to the day. To effect this a large part of the work has been rewritten, and the whole enlarged by nearly one-fourth, notwithstanding which the price has been kept at its former very moderate rate. By the use of a close, though very legible type, an unusually large amount of matter is condensed in its pages, the two volumes containing as much as four or five ordinary octavos. This, combined with the most careful mechanical execution, and its very durable binding, renders it one of the cheapest works accessible to the profession. Every subject properly belonging to the domain of surgery is treated in detail, so that the student who possesses this work may be said to have in it a surgical library.

We have seldom read a work with the practical value of which we have been more impressed. Every chapter is so concisely put together, that the busy practitioner, when in difficulty, can at once find the information he requires. His work is cosmopolitan, the surgery of the world being fully represented in it. The work, in fact, is so historically unprejudiced, and so eminently practical, that it is almost a false compliment to say that we believe it to be destined to occupy a foremost place as a work of reference, while a system of surgery like the present system of surgery is the practice of surgeons. The printing and binding of the work is unexceptionable; indeed, it contrasts, in the latter respect, remarkably with English medical and surgical cloth-bound publications, which are generally so wretchedly stitched as to require re-binding before they are any time in use.—*Dub. Journ. of Med. Sci.*, March, 1874.

Dr. Gross's Surgery, a great work, has become still greater, both in size and merit, in its most recent form. The difference in actual number of pages is not more than 130, but the size of the page having been increased to what we believe is technically termed "elephant," there has been room for considerable additions, which, together with the alterations, are improvements.—*Lond. Lancet*, Nov. 16, 1872.

It combines, as perfectly as possible, the qualities of a text-book and work of reference. We think this last edition of Gross's "Surgery," will confirm his title of "*Primus inter Pares.*" It is learned, scholar-like, methodical, precise, and exhaustive. We scarcely think any living man could write so complete and faultless a treatise, or comprehend more solid, instructive matter in the given number of pages. The labor must have been immense, and the work gives evidence of great powers of mind, and the highest order of intellectual discipline and methodical disposition and arrangement of acquired knowledge and personal experience.—*N.Y. Med. Journ.*, Feb. 1873.

As a whole, we regard the work as the representative "System of Surgery" in the English language.—*St. Louis Medical and Surg. Journ.*, Oct. 1872.

The two magnificent volumes before us afford a very complete view of the surgical knowledge of the day. Some years ago we had the pleasure of presenting the first edition of Gross's Surgery to the profession as a work of unrivalled excellence; and now we have the result of years of experience, labor, and study, all condensed upon the great work before us. And to students or practitioners desirous of enriching their library with a treasure of reference, we can simply commend the purchase of these two volumes of immense research.—*Cincinnati Lancet and Observer*, Sept. 1872.

A complete system of surgery—not a mere text-book of operations, but a scientific account of surgical theory and practice in all its departments.—*Brit. and For. Med Chir. Rev.*, Jan. 1873.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DISEASES, INJURIES, and Malformations of the Urinary Bladder, the Prostate Gland, and the Urethra. Third Edition, thoroughly Revised and Condensed, by SAMUEL W. GROSS, M.D., Surgeon to the Philadelphia Hospital.

In one handsome octavo volume of 574 pages, with 170 illustrations: cloth, $4 50. (*Just Issued.*)

For reference and general information, the physician or surgeon can find no work that meets their necessities more thoroughly than this, a revised edition of an excellent treatise, and no medical library should be without it. Replete with handsome illustrations and good ideas, it has the unusual advantage of being easily comprehended, by the reasonable and practical manner in which the various subjects are systematized and arranged. We heartily recommend it to the profession as a valuable addition to the important literature of diseases of the urinary organs.—*Atlanta Med. Journ.*, Oct. 1876.

It is with pleasure we now again take up this old work in a decidedly new dress. Indeed, it must be regarded as a new book in very many of its parts. The chapters on "Diseases of the Bladder," "Prostate Body," and "Lithotomy," are splendid specimens of descriptive writing; while the chapter on "Stricture" is one of the most concise and clear that we have ever read.—*New York Med. Journ.*, Nov. 1876.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON FOREIGN BODIES IN THE AIR-PASSAGES.

In 1 vol. 8vo., with illustrations, pp. 468, cloth, $2 75.

DRUITT (ROBERT), M.R.C.S., &c.

THE PRINCIPLES AND PRACTICE OF MODERN SURGERY.

A new and revised American, from the eighth enlarged and improved London edition. Illustrated with four hundred and thirty-two wood engravings. In one very handsome octavo volume, of nearly 700 large and closely printed pages, cloth, $4 00; leather, $5 00.

All that the surgical student or practitioner could desire.—*Dublin Quarterly Journal.*

It is a most admirable book. We do not know when we have examined one with more pleasure.—*Boston Med. and Surg. Journal.*

In Mr. Druitt's book, though containingonly some seven hundred pages, both the principles and the practice of surgery are treated, and so clearly and perspicuously, as to elucidate every important topic. We have examined the book most thoroughly, and can say that this success is well merited. His book, moreover, possesses the inestimable advantages of having the subjects perfectly well arranged and classified and of being written in a style at once clear and succinct.—*Am. Journal of Med. Sciences.*

HAMILTON (FRANK H.) M.D., LL.D.,

Surgeon to the Bellevue Hospital, New York.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS

Sixth edition, thoroughly revised, and much improved. In one very handsome octavo volume of over 900 pages, with 352 illustrations. Cloth, $5.50; leather, $6.50; half Russia, raised bands, $7.00.

The demand which has so speedily exhausted five large editions of this work, shows that the author has succeeded in supplying a want, felt by the profession at large, of an exhaustive treatise on a frequent and troublesome class of accidents. The unanimous voice of the profession abroad, as well as at home, has pronounced it the most complete work to which the surgeon can refer for information respecting the details of the subject. In the preparation of this new edition, the author has added a chapter on General Prognosis: that on Fractures of the Patella has been entirely rewritten, in order that the results of a recent exhaustive study of this subject might be given, and, in fact, the entire matter of the book has undergone most thorough revision. A number of illustrations have been omitted to make place for new ones, and a few have been inserted from the German edition, published at Göttingen in 1877.

So many kind expressions of welcome have been showered upon each successive edition of this valuable treatise, that scarcely anything remains for us to do but to extend the customary cordial greeting. It is the only complete work on the subject of Fractures in the English language. We congratulate the accomplished author on the deserved success of his work, and hope that he may live to have many succeeding editions pass under his skilled supervision.—*Phila. Coll. and Clin. Record*, Nov. 15, 1880.

Dr Hamilton has devoted great labor to the study of these subjects. His large experience, extended research, and patient investigation have made him one of the highest authorities among living writers in this branch of surgery This work is systematic and practical in its arrangement, and presents its subject matter clearly and forcibly to the reader or student.—*Maryland Medical Journal*, Nov. 15, 1880.

The only complete work on its subject in the English tongue, and, indeed, may now be said to be the only work of its kind in any tongue. It would require an exceedingly critical examination to detect in it any particulars in which it might be improved. The work is a monument to American surgery, and will long serve to keep green the memory of its venerable author.—*Michigan Med. News*, Nov. 10, 188 .

Universal verdict has pronounced it, humanly speaking, a perfect treatise upon this subject. As it is the only complete and illustrated work in any language treating of fracture and dislocations, it is safe to affirm that every wide-awake surgeon and general practitioner will regard it as indispensable to the safe and pleasant conduct of their professional work —*Detroit Lancet*, Nov. 18, 1880.

The book is known to be the only complete treati e in the English language, or in any language, and needs no recommendation, If there should still be a surgeon who does not have the book in his library, we advise him to get it immediately.—*Buffalo Med. and Surg. Journ.*, Dec. 1880

This is the sixth edition of the only work extant devoted exclusively to fractures and dislocations. That no ambitious surgeon has aspired to enter this field as a rival to Prof. Hamilton is ample testimony to the thoroughness and completeness with which he has done his work.—*Ohio Med. Recorder*, Dec 1880.

ASHHURST (JOHN, Jr.), M.D.,

Prof. of Clinical Surgery, Univ. of Pa., Surgeon to the Episcopal Hospital, Philadelphia.

THE PRINCIPLES AND PRACTICE OF SURGERY.

Second edition, enlarged and revised. In one very large and handsome octavo volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7.50. (*Just Ready.*)

Conscientiousness and thoroughness are two very marked traits of character in the author of this book. Out of these traits largely has grown the success of his mental fruit in the past, and the present offer seems in no wise an exception to what has gone before. The general arrangement of the volume is the same as in the first edition, but every part has been carefully revised, and much new matter added.—*Phila. Med. Times*, Feb. 1, 1879.

We have previously spoken of Dr. Ashhurst's work in terms of praise. We wish to reiterate those terms here, and to add that no more satisfactory representation of modern surgery has yet fallen from the press. In point of judicial fairness, of power of condensation, of accuracy and conciseness of expression and thoroughly good English, Prof. Ashhurst has no superior among the surgical writers in America.—*Am. Practitioner*, Jan. 1879.

The attempt to embrace in a volume of 1000 pages the whole field of surgery, general and special, would be a hopeless task unless through the most tireless industry in collating and arranging, and the wisest judgment in condensing and excluding. These facilities have been abundantly employed by the author, and he has given us a most excellent treatise, brought up by the revision for the second edition to the latest date. Of course this book is not designed for specialists, but as a course of general surgical knowledge and for general practitioners, and as a text-book for students it is not surpassed by any that has yet appeared, whether of home or foreign authorship.—*N. Carolina Med. Journal*, Jan. 1879.

Ashhurst's Surgery is too well known in this country to require special commendation from us. This, its second edition, enlarged and thoroughly revised, brings it nearer our idea of a model text-book than any recently published treatise. Though numerous additions have been made, the size of the work is not materially increased The main trouble of text-books of modern times is that they are too cumbersome. The student needs a book which will furnish him the most information in the shortest time. In every respect this work of Ashhurst is the model text-book—full, comprehensive and compact.—*Nashville Jour. of Med. and Surg.*, Jan. '79.

The favorable reception of the first edition is a guarantee of the popularity of this edition, which is fresh from the editor's hands with many enlargements and improvements. The author of this work is deservedly popular as an editor and writer, and his contributions to the literature of surgery have gained for him wide reputation. The volume now offered the profession will add new laurels to those already won by previous contributions. We can only add that the work is well arranged, filled with practical matter, and contains in brief and clear language all that is necessary to be learned by the student of surgery whilst in attendance upon lectures, or the general practitioner in his daily routine practice.—*Md. Med. Journal*, Jan. 1879.

The fact that this work has reached a second edition so very soon after the publication of the first one, speaks more highly of its merits than anything we might say in the way of commendation. It seems to have immediately gained the favor of students and physicians.—*Cincin. Med. News*, Jan. '79.

BRYANT (*THOMAS*), *F.R.C.S.*,

Surgeon to Guy's Hospital.

THE PRACTICE OF SURGERY.

Third American, from the Second and Revised English Edition. Thoroughly revised and much improved, by John B. Roberts, M.D. In one large and very handsome imperial octavo volume of over 1000 pages, with 672 illustrations. Cloth, $6 50; leather, $7 50; very handsome half Russia, raised bands, $8 00. (*Just Ready.*)

The marked success of this work on both sides of the Atlantic shows that the author has succeeded in the effort to give the student and practitioner a sound and trustworthy guide in the practice of surgery.

In preparing a new edition, it has seemed best, in order to adapt the work more thoroughly to the needs of the native student, that it should receive the benefits of a revision by an American editor, who should not only incorporate the most recent discoveries, but also the modes of procedure, which must necessarily vary with the practices of different countries.

The work is now confidently presented as worthy a continuance of the very distinguished success which has marked the reception of the previous editions.

ERICHSEN (*JOHN E.*),

Professor of Surgery in University College, London, etc.

THE SCIENCE AND ART OF SURGERY; being a Treatise on Surgical Injuries, Diseases, and Operations.

Carefully revised by the author from the Seventh and enlarged English Edition. Illustrated by eight hundred and sixty two engravings on wood. In two large and beautiful octavo volumes of nearly 2000 pages: cloth, $8 50; leather, $10 50; half Russia, $11 50. (*Now Ready.*)

The seventh edition is before the world as the last word of surgical science. There may be monographs which excel it upon certain points, but as a conspectus upon surgical principles and practice it is unrivalled. It will well reward practitioners to read it, for it has been a peculiar province of Mr. Erichsen to demonstrate the absolute interdependence of medical and surgical science. We need scarcely add, in conclusion, that we heartily commend the work to students that they may be grounded in a sound faith, and to practitioners as an invaluable guide at the bedside.—*Am. Practitioner*, April, 1878.

It is no idle compliment to say that this is the best edition Mr. Erichsen has ever produced of his well-known book. Besides inheriting the virtues of its predecessors, it possesses excellences quite its own. Having stated that Mr. Erichsen has incorporated into this edition every recent improvement in the science and art of surgery, it would be a supererogation to give a detailed criticism. In short, we unhesitatingly aver that we know of no other single work where the student and practitioner can gain at once so clear an insight into the principles of surgery, and so complete a knowledge of the exigencies of surgical practice.—*London Lancet*, Feb. 14, 1878.

For the past twenty years Erichsen's Surgery has maintained its place as the leading text-book, not only in this country, but in Great Britain. That it is able to hold its ground, is abundantly proven by the thoroughness with which the present edition has been revised, and by the large amount of valuable material that has been added. Aside from this, one hundred and fifty new illustrations have been inserted, including quite a number of microscopical appearances of pathological processes. So marked is this change for the better, that the work almost appears as an entirely new one.—*Med. Record*, Feb. 23, 1878.

Of the many treatises on Surgery which it has been our task to study, or our pleasure to read, there is none which in all points has satisfied us so well as the classic treatise of Erichsen. His polished, clear style, his freedom from prejudice and hobbies, his unsurpassed grasp of his subject, and vast clinical experience, qualify him admirably to write a model text-book. When we wish, at the least cost of time, to learn the most of a topic in surgery, we turn, by preference, to his work. It is a pleasure, therefore, to see that the appreciation of it is general, and has led to the appearance of another edition.—*Med. and Surg. Reporter*, Feb. 2, 1878.

Notwithstanding the increase in size, we observe that much old matter has been omitted. The entire work has been thoroughly written up, and not merely amended by a few extra chapters. A great improvement has been made in the illustrations. One hundred and fifty new ones have been added, and many of the old ones have been redrawn. The author highly appreciates the favor with which his work has been received by American surgeons, and has endeavored to render his latest edition more than ever worthy of their approval. That he has succeeded admirably, must, we think, be the general opinion. We heartily recommend the book to both student and practitioner.—*N. Y. Med. Journal*, Feb. 1878.

HOLMES (*TIMOTHY*), *M.D.*,

Surgeon to St. George's Hospital, London.

SURGERY, ITS PRINCIPLES AND PRACTICE.

In one handsome octavo volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; leather, $7; half Russia, $7 50. (*Just Issued.*)

This is a work which has been looked for on both sides of the Atlantic with much interest. Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and perhaps the most brilliant writer upon surgical subjects in England. It is a book for students—and an admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its proper limits has not impaired its force and distinctness.—*N. Y. Med. Record*, April 14, 1876.

It will be found a most excellent epitome of surgery by the general practitioner who has not the time to give attention to more minute and extended works and to the medical student. In fact, we know of no one we can more cordially recommend. The author has succeeded well in giving a plain and practical account of each surgical injury and disease, and of the treatment which is most commonly advisable. It will no doubt become a popular work in the profession, and especially as a text-book.—*Cincinnati Med. News*, April, 1876.

ASHTON ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS: with remarks on Habitual Constipation. Second American, from the fourth and enlarged London Edition. With illustrations. In one 8vo vol. of 287 pages, cloth, $3 25.

SARGENT ON BANDAGING AND OTHER OPERATIONS OF MINOR SURGERY. New edition, with an additional chapter on Military Surgery. One 12mo. vol. of 383 pages with 184 wood-cuts. Cloth, $1 75.

WELLS (*J. SOELBERG*),

Professor of Ophthalmology in King's College Hospital, &c.

A TREATISE ON DISEASES OF THE EYE. Third American,

from the Third London Edition. Thoroughly revised, with copious additions, by Chas. S. Bull, M D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with about 250 engravings on wood, and six colored plates Together with selections from the Test-types of Jaeger and Snellen In one large and very handsome octavo volume of 900 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6.50. (*Just Ready.*)

The long-continued illness of the author, with its fatal termination, has kept this work for some time out of print, and has deprived it of the advantage of the revision which he sought to give it during the last years of hi life. This edition has therefore been placed under the editorial supervision of Dr. Bull, who has labored earnestly to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision. To accomplish this, considerable additions have been required, and the work is now presented in the confidence that it will fully deserve a continuance of the very marked favor with which it has hitherto been greeted as a complete, but concise, exposition of the principles and facts of its important department of medical science.

The additions made in the previous American editions by Dr. Hays have been retained, including the very full series of illustrations and the test-types of Jaeger and Snellen.

This new edition of Dr. Wells's great work on the eye will be welcomed by the profession at large as well as by the oculist. It contains much new matter relating to treatment and pathology, and is brought thoroughly up with the present status of ophthalmology. Its chapter on refraction and accommodation—a subject much discussed of late years, and of great importance—is exceedingly complete.—*Louisville Med. News*, Nov. 13, 1880.

The merits of Wells's treatise on diseases of the eye have been so universally acknowledged and are so familiar to all who profess to have given any attention to ophthalmic surgery, that any discussion of them at this late day will be a work of supererogation. Very little that is practically useful in recent ophthalmic literature has escaped the editor, and the third American edition is well up to the times. As a text-book on ophthalmic surgery for the English-speaking practitioner, it is without a rival.—*Am. Journ. of Med. Sci.*, Jan. 1881.

The work has justly held a high place in English ophthalmic literature, and at the time of its first appearance was the best treatise of its kind in the language. In the second edition, the author showed industrious research in adding new material from every quarter, and his spirit was eminently candid. A work thus built up by honest effort should not be suffered to die, and we are pleased to receive this third edition from the hands of Dr. Bull. His labor has been arduous, as the very great number of additions bracketed with his initial testify. Under the editorship which the third edition has enjoyed, the work is sure to sustain its good reputation, and to maintain its usefulness.—*N. Y. Med. Journ.*, Jan. 1881.

There is really no work which approaches it in adaptation to the wants of the general practitioner, while the most advanced specialist cannot rise from a perusal of its ample pages without having added to his knowledge. The American editor, Dr. Bull, won his spurs in ophthalmology some time back. His additions to the work of the lamented Wells are many, judicious, and timely, and in just so much have added to its value.—*Am. Practitioner*, Jan. 1881.

NETTLESHIP (*EDWARD*), *F.R.C.S.*,

Ophthalmic Surg. and Lect. on Ophth. Surg. at St. Thomas' Hospital, London.

MANUAL OF OPHTHALMIC MEDICINE.

In one royal 12mo. volume of over 350 pages, with 89 illustrations. Cloth, $2. (*Just Ready.*)

The author is to be congratulated upon the very successful manner in which he has accomplished his task; he has succeeded in being concise without sacrificing clearness, and, including the whole ground covered by more voluminous text-books, has given an excellent *résumé* of all the practical information they contain. We do not hesitate to pronounce Mr Nettleship's book the best manual on ophthalmic surgery for the use of students and "busy practitioners" with which we are acquainted.—*Am. Jour. Med. Sciences*, April, 1880.

CARTER (*R. BRUDENELL*), *F.R.C.S.*,

Ophthalmic Surgeon to St. George's Hospital, etc.

A PRACTICAL TREATISE ON DISEASES OF THE EYE.

Edited, with test-types and Additions, by JOHN GREEN, M.D. (of St. Louis, Mo.). In one handsome octavo volume of about 500 pages, and 124 illustrations. Cloth, $3 75. (*Just Issued.*)

It is with great pleasure that we can endorse the work as a most valuable contribution to practical ophthalmology. Mr. Carter never deviates from the end he has in view, and presents the subject in a clear and concise manner, easy of comprehension, and hence the more valuable. We would especially commend, however, as worthy of high praise, the manner in which the therapeutics of disease of the eye is elaborated, for here the author is particularly clear and practical, where other writers are unfortunately too often deficient. The final chapter is devoted to a discussion of the uses and selection of spectacles, and is admirably compact, plain, and useful, especially the paragraphs on the treatment of presbyopia and myopia. In conclusion, our thanks are due the author for many useful hints in the great subject of ophthalmic surgery and therapeutics, a field where of late years we glean but a few grains of sound wheat from a mass of chaff.—*New York Medical Record*, Oct. 23, 1875.

BROWNE (*EDGAR A.*),

Surgeon to the Liverpool Eye and Ear Infirmary, and to the Dispensary for Skin Diseases.

HOW TO USE THE OPHTHALMOSCOPE.

Being Elementary Instructions in Ophthalmoscopy, arranged for the Use of Students. With thirty-five illustrations. In one small volume royal 12mo. of 120 pages: cloth, $1. (*Now Ready.*)

LAURENCE'S HANDY-BOOK OF OPHTHALMIC SURGERY, for the use of Practitioners. Second edition, revised and enlarged With numerous illustrations. In one very handsome octavo volume, cloth, $2 75.

LAWSON'S INJURIES TO THE EYE, ORBIT, AND EYELIDS: their Immediate and Remote Effects. With about one hundred illustrations. In one very handsome octavo volume, cloth, $3 50.

BURNETT (CHARLES H.), M.A., M.D.,

Aural Surg. to the Presb. Hosp., Surgeon-in-charge of the Infir. for Dis. of the Ear, Phila.

THE EAR, ITS ANATOMY, PHYSIOLOGY, AND DISEASES.

A Practical Treatise for the Use of Medical Students and Practitioners. In one handsome octavo volume of 615 pages, with eighty-seven illustrations: cloth, $4 50; leather, $5 50; half Russia, $6 00. (*Now Ready.*)

Foremost among the numerous recent contributions to aural literature will be ranked this work of Dr. Burnett. It is impossible to do justice to this volume of over 600 pages in a necessarily brief notice. It must suffice to add that the book is profusely and accurately illustrated, the references are conscientiously acknowledged, while the result has been to produce a treatise which will henceforth rank with the classic writings of Wilde and Von Troltsch.—*The Lond. Practitioner*, May, 1879.

On account of the great advances which have been made of late years in otology, and of the increased interest manifested in it, the medical profession will welcome this new work, which presents clearly and concisely its present aspect, whilst clearly indicating the direction in which further researches can be most profitably carried on. Dr. Burnett from his own matured experience, and availing himself of the observations and discoveries of others, has produced a work which, as a text-book, stands *facile princeps* in our language. We had marked several passages as well worthy of quotation and the attention of the general practitioner, but their number and the space at our command forbid. Perhaps it is better, as the book ought to be in the hands of every medical student, and its study will well repay the busy practitioner in the pleasure he will derive from the agreeable style in which many otherwise dry and mostly unknown subjects are treated. To the specialist the work is of the highest value, and his sense of gratitude to Dr. Burnett will, we hope, be proportionate to the amount of benefit he can obtain from the careful study of the book, and a constant reference to its trustworthy pages.—*Edinburgh Med. Jour.*, Aug. 1878.

TAYLOR (ALFRED S.), M.D.,

Lecturer on Med. Jurisp. and Chemistry in Guy's Hospital.

A MANUAL OF MEDICAL JURISPRUDENCE.

Eighth American edition. Thoroughly revised and rewritten. Edited by JOHN J. REESE, M.D., Prof. of Med. Jurisp. and Toxicology in the Univ. of Penn. In one large octavo volume of 933 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready*)

The American editions of this standard manual have for a long time laid claim to the attention of the profession in this country; and that the profession has recognized this claim with favor is proven by the call for frequent new editions of the work. This one, the eighth, comes before us as embodying the latest thoughts and emendations of Dr. Taylor, upon the subject to which he devoted his life, with an assiduity and success which made him *facile princeps* among English writers on medical jurisprudence. Both the author and the book have made a mark too deep to be affected by criticism, whether it be censure or praise. In this case, however, we should only have to seek for laudatory terms.—*Am. Journ. of Med. Sci.*, Jan. 1881.

It is not very often that a medical book reaches its tenth edition, or that the last earthly labor is performed by the author in retouching the work that first came from his hand thirty-five years before. All this, however, has happened in the case of Dr. Taylor and his classical treatise. The pen dropped from the grasp only when the shadows of old age were rapidly deepening into the darkness of death. Under the circumstances, all the journalist has to do is to announce, not criticize the completed task. The value of the gem is too well known to require more than the telling that the master-hand has rebrightened its facets and polished its angles before leaving it as his legacy to his brethren in the profession.—*Phila Med. Times*, Dec. 4, 1880.

It will suffice to remark that this new edition shows the signs of judicious revision. A great number of illustrative medico-legal cases which have occurred since the last edition was published are cited in their proper connection, and add much to the interest and value of the work; they comprise the bulk of the additions to the text. As an indication of the freshness of the work, we notice numerous references to medico-legal experience that has transpired during the year just ended; among these is a comment by the American editor upon that midsummer madness, the Tanner fasting exploit of last August. In these features and in others there is ample evidence that this admirable book will maintain its high place as a standard authority concerning the matters of which it treats.—*Boston Med. and Surg. Journal*, Jan. 13, 1881.

BY THE SAME AUTHOR.

THE PRINCIPLES AND PRACTICE OF MEDICAL JURISPRUDENCE.

Second Edition, Revised, with numerous Illustrations. In two large octavo volumes, cloth, $10 00; leather, $12 00

This great work is now recognised in England as the fullest and most authoritative treatise on every department of its important subject. In laying it, in its improved form, before the American profession, the publishers trust that it will assume the same position in this country.

BY THE SAME AUTHOR.

POISONS IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE.

Third American, from the Third and Revised English Edition. In one large octavo volume of 850 pages; cloth, $5 50; leather, $6 50. (*Just Issued.*)

The present is based upon the two previous editions; "but the complete revision rendered necessary by time has converted it into a new work." This statement from the preface contains all that it is desired to know in reference to the new edition. The works of this author are already in the library of every physician who is liable to be called upon for medico-legal testimony (and what one is not?), so that all that is required to be known about the present book is that the author has kept it abreast with the times. What makes it now, as always, especially valuable to the practitioner is its conciseness and practical character, only those poisonous substances being described which give rise to legal investigations.—*The Clinic*, Nov. 6, 1875.

Dr. Taylor has brought to bear on the compilation of this volume, stores of learning, experience, and practical acquaintance with his subject, probably far beyond what any other living authority on toxicology could have amassed or utilized. He has fully sustained his reputation by the consummate skill and legal acumen he has displayed in the arrangement of the subject-matter, and the result is a work on Poisons which will be indispensable to every student or practitioner in law and medicine.—*The Dublin Journ. of Med Sc.*, Oct. 1875.

ROBERTS (WILLIAM), M.D.,
Lecturer on Medicine in the Manchester School of Medicine, &c.

A PRACTICAL TREATISE ON URINARY AND RENAL DISEASES, including Urinary Deposits. Illustrated by numerous cases and engravings. Third American, from the Third Revised and Enlarged London Edition. In one large and handsome octavo volume of over 600 pages. Cloth, $4. (*Just Ready.*)

THOMPSON (SIR HENRY),
Surgeon and Professor of Clinical Surgery to University College Hospital.

LECTURES ON DISEASES OF THE URINARY ORGANS. With illustrations on wood. Second American from the Third English Edition. In one neat octavo volume. Cloth, $2 25. (*Just Issued.*)

BY THE SAME AUTHOR.

ON THE PATHOLOGY AND TREATMENT OF STRICTURE OF THE URETHRA AND URINARY FISTULÆ. With plates and wood-cuts. From the third and revised English edition. In one very handsome octavo volume, cloth, $3 50. (*Lately Published.*)

TUKE (DANIEL HACK), M.D.,
Joint author of The Manual of Psychological Medicine, &c.

ILLUSTRATIONS OF THE INFLUENCE OF THE MIND UPON THE BODY IN HEALTH AND DISEASE. Designed to illustrate the Action of the Imagination. In one handsome octavo volume of 416 pages, cloth, $3 25. (*Lately Issued.*)

BLANDFORD (G. FIELDING), M.D., F.R.C.P.,
Lecturer on Psychological Medicine at the School of St. George's Hospital, &c.

INSANITY AND ITS TREATMENT: Lectures on the Treatment, Medical and Legal, of Insane Patients. With a Summary of the Laws in force in the United States on the Confinement of the Insane. By ISAAC RAY, M. D. In one very handsome octavo volume of 471 pages; cloth, $3 25.

It satisfies a want which must have been sorely felt by the busy general practitioners of this country. It takes the form of a manual of clinical description of the various forms of insanity, with a description of the mode of examining persons suspected of insanity. We call particular attention to this feature of the book, as giving it a unique value to the general practitioner. If we pass from theoretical considerations to descriptions of the varieties of insanity as actually seen in practice and the appropriate treatment for them, we find in Dr. Blandford's work a considerable advance over previous writings on the subject. His pictures of the various forms of mental disease are so clear and good that no reader can fail to be struck with their superiority to those given in ordinary manuals in the English language or (so far as our own reading extends) in any other.—*London Practitioner*, Feb. 1871.

LEA (HENRY C.).

SUPERSTITION AND FORCE: ESSAYS ON THE WAGER OF LAW, THE WAGER OF BATTLE, THE ORDEAL, AND TORTURE. Third Revised and Enlarged Edition. In one handsome royal 12mo. volume of 552 pages. Cloth, $2 50. (*Just Ready.*)

This valuable work is in reality a history of civilization as interpreted by the progress of jurisprudence. . . . In "Superstition and Force" we have a philosophic survey of the long period intervening between primitive barbarity and civilized enlightenment. There is not a chapter in the work that should not be most carefully studied, and however well versed the reader may be in the science of jurisprudence, he will find much in Mr. Lea's volume of which he was previously ignorant. The book is a valuable addition to the literature of social science.—*Westminster Review*, Jan. 1880.

The appearance of a new edition of Mr. Henry C. Lea's "Superstition and Force" is a sign that our highest scholarship is not without honor in its native country. Mr. Lea has met every fresh demand for his work with a careful revision of it, and the present edition is not only fuller and, if possible, more accurate than either of the preceding, but, from the thorough elaboration, is more like a harmonious concert and less like a batch of studies.—*The Nation*, Aug. 1, 1878.

Many will be tempted to say that this, like the "Decline and Fall," is one of the uncriticizable books. Its facts are innumerable, its deductions simple and inevitable, and its *chevaux-de-frise* of references bristling and dense enough to make the keenest, stoutest, and best equipped assailant think twice before advancing. Nor is there anything controversial in it to provoke assault. The author is no polemic. Though he obviously feels and thinks strongly, he succeeds in attaining impartiality. Whether looked on as a picture or a mirror, a work such as this has a lasting value.—*Lippincott's Magazine*, Oct. 1878.

BY THE SAME AUTHOR.

STUDIES IN CHURCH HISTORY. THE RISE OF THE TEMPORAL POWER—BENEFIT OF CLERGY—EXCOMMUNICATION. In one large royal 12mo. volume of 516 pp.; cloth, $2 75. (*Lately Published.*)

The story was never told more calmly or with greater learning or wiser thought. We doubt, indeed, if any other study of this field can be compared with this for clearness, accuracy, and power.—*Chicago Examiner*, Dec. 1870.

Mr. Lea's latest work, "Studies in Church History," fully sustains the promise of the first. It deals with three subjects—the Temporal Power, Benefit of Clergy, and Excommunication, the record of which has a peculiar importance for the English student, and is a chapter on Ancient Law likely to be regarded as final. We can hardly pass from our mention of such works as these—with which that on "Sacerdotal Celibacy" should be included—without noting the literary phenomenon that the head of one of the first American houses is also the writer of some of its most original books.—*London Athenæum*, Jan. 7, 1871.

NEW MEDICAL WORKS—Just Ready.

FLINT'S PRACTICE—New Edition.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; Designed for the Use of Students and Practitioners of Medicine. By AUSTIN FLINT, M.D., Professor of the Principles and Practice of Medicine in Bellevue Med. College, N. Y. Fifth edition, thoroughly revised and much improved. In one large and closely printed octavo volume of 1153 pages. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7.

Practically, this edition is a new work; for so many additions and changes have been made that one well acquainted with previous editions would hardly recognize this as an old friend. The size of the volume is somewhat increased. An entire new section and several new chapters have been added. It is universally conceded that no text-book upon this subject was ever published in this country that can at all compare with it. It has long been at the very head of American text-book literature, and there can be no doubt but that it will be many years before it yields the place to others.—*Nashville Journ. of Med. and Surg*, Feb. 1881.

On the whole, the work now seems to us distinctly the best of its kind written by an American, and at least equalling anything in the language.—*Philadelphia Med. Times*, Jan. 27, 1881.

It is an able—a grand presentation of a grand subject, abreast with the last step of its forward movement, reflecting the highest honor on the man that produced it and the country that produced the man.—*So. Practitioner*, Feb. 1881.

THOMAS ON WOMEN—New and Revised Edition.

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN. By T. GAILLARD THOMAS, M.D., Prof. of Obstetrics, etc., in the College of Physicians and Surgeons, New York. Fifth edition, thoroughly revised and rewritten. In one large and handsome octavo volume of 806 pages, with 266 illustrations. Cloth, $5; leather, $6; half Russia, $6 50.

Prof. Thomas's work has acquired a degree of popularity and received marks of professional favor second to no work on gynæcology that has been issued from the press. It is the student's book, *par excellence*, and is recognized as such the world over. The clear and charming style of the author, his positive way of stating his opinions, and the lucidity of his differential diagnosis, make this work a favorite with every one who reads one chapter.—*St. Louis Clinical Record*, Jan. 1881.

An examination of the work will satisfy that it is one of great merit. It is not a mere compilation from other works, but it is the fruit of the ripe thought, sound judgment, and critical observations of a learned, scientific man. It is a treasury of knowledge of the department of medicine to which it is devoted. In its present revised state it certainly holds a foremost position as a gynæcological work, and will continue to be regarded as a standard authority.—*Cincinnati Med. News*, Dec. 1880.

BRYANT'S SURGERY—New Edition.

THE PRACTICE OF SURGERY. By THOMAS BRYANT, F.R.C.S., Surgeon to Guy's Hospital, London. Third American, from the Second and revised English edition. Thoroughly revised and much improved, by JOHN B. ROBERTS, M.D. In one large and very handsome imperial octavo volume of over 1050 pages, with 767 illustrations. Cloth, $6 50; leather, $7 50; very handsome half Russia, raised bands, $8.

Without freighting his book with multiplied details and wearying descriptions of allied methods of procedure, he is ample enough for reference on all the departments of surgery, not omitting such strict specialties as dental, ophthalmic, military, orthopædic and gynæcological surgery. Some of these chapters are written by specialists in these respective branches, and all are amply sufficient for any one not himself aiming at special practice. The labors of the American editor deserve unqualified praise. His additions to the author's text are numerous, judicious, and germane. They add very distinctly to the value of the original treatise, and give a more equitable illustration of the part taken by American surgeons than the author was able to do, owing to his less familiarity with our current literature.—*Phila. Med. and Surg. Reporter*, Feb. 12, '81.

The third edition has been carefully revised, and many additions, besides numerous new illustrations, added, so that the work represents, in a concise and practical form, our present knowledge in this important branch of medical science. Dr. Roberts, the American editor, has introduced many valuable additions, relating especially to the opinions of American surgeons.—*Buff. Med. and Surg. Journ.*, Feb. 1881.

The especial attractions of the work are not only its highly practical character, but also the conciseness with which its contents are arranged. Every subject in surgery is treated of in an exhaustive manner, and yet so thoroughly has the author succeeded in condensing the matter that the publishers have been able to present the work in one volume. The arrangement is perfect, the illustrations are numerous, and in every instance well executed.—*Nashville Journal of Medicine and Surgery*, Feb. 1881.

TAYLOR'S MEDICAL JURISPRUDENCE—New Edition.

A MANUAL OF MEDICAL JURISPRUDENCE. By ALFRED S. TAYLOR, M.D., late Lecturer on Medical Jurisprudence and Chemistry in Guy's Hospital, London. Eighth American edition. Edited by JOHN J. REESE, M.D., Professor of Medical Jurisprudence and Toxicology in the Univ. of Penna. In one large and very handsome 8vo. vol. of 933 pages, with illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50.

The best manual of the subjects embraced to be found in the market. Taylor's Manual should be found in every medical library. It is short, clear and definite in its phraseology—qualities which give it precedence over every book of the kind we have examined.—*St. Louis Clin. Record*, Jan 1881.

No work in any language, in the same department of medicine, is of higher authority, if as high. With both medical and legal gentlemen its statements are decisive. The work is fully up to the present state of knowledge, and will, for a long time to come, be regarded as the standard work of medical jurisprudence.—*Cincinnati Med. News*, Jan. 1881.

A more complete work, a higher authority on all the subjects embraced within its scope, has not yet fallen from the press.—*American Practitioner*, Feb. 1881.

The American editions of this standard manual have for a long time laid claim to the attention of the profession in this country; and that the profession has recognized this claim with favor is proven by the call for frequent new editions of the work. This one, the eighth, comes before us as embodying the latest thoughts and emendations of Dr. Taylor, upon the subject to which he devoted his life, with an assiduity and success which made him *facile princeps* among English writers on medical jurisprudence. Both the author and the book have made a mark too deep to be affected by criticism, whether it be censure or praise. In this case, however, we should only have to seek for laudatory terms.—*Am. Journ. of Med. Sciences*, Jan. 1881.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing its sixty-first year, the publishers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "THE MEDICAL NEWS AND ABSTRACT," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of FIVE DOLLARS *per annum*.

The "NEWS AND ABSTRACT" consists of sixty-four pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, contributed by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "MONTHLY ABSTRACT," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "NEWS AND ABSTRACT" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum),	Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance,	Five Dollars.

The MEDICAL NEWS AND ABSTRACT, invariably in advance, Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

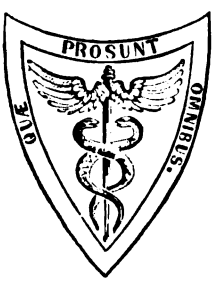
MEDICAL NEWS

AND

ABSTRACT.

EDITED BY

I. MINIS HAYS, A.M., M.D.



PHILADELPHIA:
HENRY C. LEA'S SON & CO.
1881.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.
Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

Entered according to the Act of Congress, in the year 1881, by HENRY C. LEA'S SON & Co., in the Office of the Librarian of Congress. All rights reserved.

SOLD ONLY BY SUBSCRIPTION.

REYNOLDS'S SYSTEM OF MEDICINE—Revised Edition—Complete in 3 Vols.

A SYSTEM OF MEDICINE.

EDITED BY J. RUSSELL REYNOLDS, M.D.,

Prof. of the Principles and Practice of Medicine in University College, London.

WITH NOTES AND ADDITIONS

BY HENRY HARTSHORNE, M.D.,

Late Professor of Hygiene in the University of Pennsylvania.

In three large and handsome royal octavo volumes, containing 3052 closely printed double column pages, with 317 illustrations. (Now Ready.)

PRICES.

	Cloth.	Sheep.	Half Russia.
Per volume	$5 00	$6.00	$6.50
Per set	15.00	18.00	19.50

Reynolds's System, as a work of reference in medicine, is unexcelled and unequalled, and should be in the library of every physician. Dr. Hartshorne, the American editor, has contributed articles on cholera morbus, cholera infantum, trichina spiralis, bronchocele, pernicious anæmia, and spermatorrhœa, besides making such additions to many other articles as the progress of medical science since the volumes first appeared, required. The task he undertook has been well performed, and the thanks of all American physicians are due to the American editor for affording them the opportunity of obtaining at a reasonable price such a magnificent cyclopædia of the practice of medicine, embodying as it does the views of the most learned members of the medical profession of Great Britain. We earnestly advise all our readers to buy the volumes and *read them.*—*Canadian Journ. of Med. Sci.*, Oct. 1880

It gives us pleasure to recommend most cordially this System of Medicine, not merely to the student but also to the busy practitioner of medicine.—*Amer. Journ. of Med. Sciences*, Aug. 1880.

As a work of reference, Reynolds's System of Medicine is the most thorough and complete in the English language. Each subject has assigned it a distinct author, whose special merits are fully and clearly put before the reader. We know of no work whose value so appeals to the wants of the profession and so important to the practitioner.—*Southern Medical Record*, Nov. 20, 1880.

Regarding the work as a whole, we give it our earnest commendation. It places within the reach of the average physician a series of monographs, written by some of the most eminent men of the age, upon an extremely wide range of subjects. It is the latest and best cyclopædic work on practical medicine written in our language.—*St. Louis Clinical Record*, Aug. 1880.

Valuable as the work was when issued in England, the labors of Dr. Hartshorne have added very greatly to its worth, and it can now but be regarded as the best encyclopædia of medicine extant.—*American Practitioner*, Aug. 1880.

In style, economy of space clearness and brevity; in comprehensiveness, excellence of description, and practical utility, it is admirable.—*Chicago Med. Rev.*, July 20, 1880.

STILLÉ & MAISCH'S DISPENSATORY—Now Ready.

THE NATIONAL DISPENSATORY;

Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, Including those Recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex.

BY ALFRED STILLÉ, M.D., LL.D.,

Prof. of Theory and Practice of Med. and of Clinical Med. in the Univ. of Pennsylvania,

AND

JOHN M. MAISCH, Ph.D.,

Prof. of Mat. Med. and Bot. in Phil. College of Pharm., Secretary to the Am. Pharm. Association.

Second Edition, thoroughly Revised, with numerous Additions.

In one very handsome octavo volume of sixteen hundred and ninety-two pages, with two hundred and thirty-nine illustrations; extra cloth, $5 75; leather, raised bands, $7 50; very handsome half Russia, raised bands and open back, $8 25.

The authors may be congratulated on the execution of a very valuable work, rich in information, and almost encyclopædic in character. This volume must be considered of great value as a work of reference, and one which fully sustains the high reputation of its distinguished authors.—*Dub. Journ. of Med. Sci.*, April, 1880.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since its publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Journ. of Pharmacy*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on the subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only *national*, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Med. Journ.*, Nov. 1879.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practising physician can afford to be without the National Dispensatory.—*Canada Med. and Surg. Journ.*, Feb. 1880.

CLINICS.

Clinical Lectures.

ON FRACTURE OF THE PATELLA. RELATIVE VALUE OF BONY AND FIBROUS UNION IN TRANSVERSE FRACTURES.

A CLINICAL LECTURE DELIVERED AT BELLEVUE HOSPITAL, DEC. 1880.

BY FRANK H. HAMILTON, M.D.,
SURGEON TO BELLEVUE HOSPITAL, NEW YORK, ETC.

GENTLEMEN: Last year I presented to the medical gentlemen and students assembled here fourteen cases of fracture of the patella, which had united by fibrous tissue. Some of these were quite old cases, and some quite recent cases; some with a short fibrous union, and in some the bond of union was quite long; but the patients were all able to walk very well, and in some the flexion and extension, and all the functions of the limbs were completely restored. At the same time I presented an analysis of 127 cases, 64 of which had been more or less under my personal observation and care. In the analysis of these cases it was found that in a large majority the union was known to be fibrous, indeed, that not in more than five or six cases was there a suspicion that bony union had taken place, and in not one was its existence proven. Subsequently these 127 cases were published in detail, with the results of the analysis, embodying certain other conclusions and inferences; and my remarks to-day are intended chiefly to supplement the observations then made, but especially in reference to the relative value of a fibrous and bony union.

First, I will repeat what was said by me on the occasion alluded to, namely, that the evidence presented by the study of cases which had come under my observation was well-nigh conclusive that a fibrous union is as useful as a bony union, and probably less liable to a renewed separation. The same was substantially shown by the cases brought before the gentlemen for their inspection. I shall pursue this subject to-day more in a theoretical point of view than by an actual study of cases.

Suppose it were possible to make a transverse fracture of this bone to unite by bone—remember that nearly all of these fractures are transverse—*with the fragments in actual contact.* What evidence has been presented, and what reason can be assigned why it should be any stronger than if the

union were fibrous? The ligamentum patellæ, although much more slender than the patella in its transverse and antero-posterior diameters, does not break once where the patella breaks ten times; yet it is subject to the same strains as the patella. In the last (6th) edition of my work on "Fractures and Dislocations," I have recorded a case seen by me in which the patella having been broken the second time by muscular action, the separation took place, not through the newly-formed fibrous ligament, but through another portion of the bone itself, proving conclusively that the new ligament, of half an inch in length, at the end of five or six months, was better able to resist the cross strain and muscular action than the original bone.

In the preceding remarks, gentlemen, I have supposed the fragments to have united by bone, while they were in actual or nearly actual contact, although no evidence has yet been presented to me that this has ever happened in the case of a transverse fracture. I see no reason, however, why it might not occasionally happen when the fragments have been broken, but not actually separated from each other through their entire thickness; nor, indeed, that it might not happen whenever the fragments having been completely separated are again, and at an early day, brought into contact, and maintained in absolute contact for a sufficient length of time. I am not disputing the possibility of close bony union, under certain possible conditions. I am only comparing the value of that close bony union with an equally close fibrous union, and the conclusion is that the fibrous union is likely to be the strongest, and, therefore, the best. A fibrous ligament here, as everywhere else in the body, is stronger than a bone of equal size, and will especially resist more successfully a cross strain.

Let us now make another supposition, namely, that the fragments have united by bone, *but with a separation of half an inch or of an inch.* Here is a specimen of that kind of union. The fragments after a transverse fracture have united by a slender bridge of bone of about one inch in length. The argument will be the same whether its length is more, or somewhat less. It is a bridge of solid bone, but of less than half the thickness of the original bone. The bridge is defective in the centre, presenting here a pretty large oval space, which was closed in before it was cleaned by a fibrous tissue. A glance will convince you that this bridge of bone could not have resisted any considerable cross strain, and that any effort to bend the knee to a right angle must almost inevitably have snapped it like a pipe stem. The bone was sent to me, and its history has not yet been obtained, but the presumption seems to be inevitable that it was taken from an anchylosed limb. In my attempt to clean it, I broke, as you will see, one side of the bridge, and it is certain that no portion of it could have withstood a bending of ten degrees, while the quadriceps retained its normal power of contraction. It requires very little mechanical or physiological learning to understand that a fibrous band of the same dimensions would have been much stronger, and, therefore, more useful than this.

If the bond of union is to be bone, then, we argue the union must be accomplished with the fragments in absolute, or nearly absolute contact; and I have no satisfactory proof that this has ever been done, nor does it seem to me that it is possible that it ever will be done, except in those rare cases in which the fracture has occurred without complete separation of the fragments; as, for example, where the anterior margins of the line of fracture are separated, and the posterior remain in contact, so that the

joint is not actually opened. This is a possibility, as this experiment upon the cadaver will illustrate. With a broad chisel and hammer, my assistant has cut or broken the patella transversely, but the thin cartilage covering its posterior surface has not been torn, and the joint is not exposed. So that while in front the fragments can be separated one-quarter of an inch, they remain in contact posteriorly. If this were the condition of the fragments from the beginning a bony union would be very possible, or quite probable. If they are separated an inch or even one-quarter of an inch completely, posteriorly as well as anteriorly, the union of bone would be accomplished under great difficulties, and probably not until after the lapse of several months, during which the joint must be kept in a state of complete immobility. It is my opinion that in all of the cases in which an examination of the specimens after death has shown that the fragments have united by bone with a separation of half an inch or more between the fragments—and the specimens of this kind of union known to exist are very few—the knees of the patients from whom they were taken, were anchylosed. Certainly it could not have been formed when the knee was in motion, and probably in all these cases there has been first a ligamentous bond, which has been gradually changed into bone.

Notice what difficulties exist in the way of union by bone. The fragments are not usually in absolute contact immediately after the accident, and experience has shown that they can seldom be brought and *maintained* in absolute contact subsequently. There is no bone in the body which under such circumstances is ever expected to unite by bone. If it does it is a rare and exceptional event, and does not occur until after many months or years of confinement of the limb. Why should it happen with the patella and not with other bones? There is no reason why it should; but there are several reasons why it should not, which do not apply in the cases of most other bones. The disadvantages under which it labours in this regard are peculiar, and nearly or quite equal to those which exist in the case of an intracapsular fracture of the neck of the femur. The synovial fluid is greatly increased in quantity, and pressing forwards occupies the space between the broken surfaces, and by distending the capsule actually increases the separation. There is very little soft tissue either in front of or behind the patella. Posteriorly the thin plate of cartilage is torn entirely across, except in those rare instances which I have supposed possible, but the existence of which has not been actually proven, where the fragments may be supposed to have separated in front, but not posteriorly. You must not forget that this fracture is almost invariably caused by great muscular action, and if under this immense strain the bone has given way, the thin and delicate cartilaginous plate posteriorly would offer only a feeble resistance to the action of the muscles and the separation would be completed. In this fracture made upon the cadaver with a chisel the synovial membrane was not torn and the joint was not opened, but the circumstances are different from those in which a fracture usually occurs in life; in this fracture produced by a chisel there was no muscular action, and the fracture could be limited to any point. You see then how difficult, if not impossible, it is to supply the bony material. There is absolutely nothing left behind the line of fracture from which repair of any kind can proceed.

In front again the periosteum is torn entirely asunder, and so also are the few scattering fibres of the tendon of the quadriceps. Even the posterior wall of the bursa patellæ is probably torn in most cases, and

nothing is left in front of the line of fracture but a thin tegumentary layer, the posterior surface of which, corresponding to the fracture is, in case the bursa has been torn, a synovial surface, which I need not tell you is unfitted for the process of repair. In the case of ordinary fracture of the long bones there is always an abundance of soft tissue to aid in the repair, and there is also in almost every case a considerable portion of periosteum which is untorn, and which bridges over a part of the chasm and contributes very largely to the future callus; the fragments are also in most cases in actual contact; and yet even under these most favourable circumstances bony union sometimes fails.

If the fragments are not therefore in actual contact there is usually, I will repeat, no source of supply for reparative material but this thin tegumentary layer in front and the lacerated fibres of the tendon of the quadriceps on the inner and outer margins of the patella, of which two, it is probable that the latter furnishes the chief supply. An examination of the lesions in the aponeurosis, which hug closely the lateral margins of the fragments, would lead us to conclude that this must be the chief source of the supply; and the fact that the new fibrous bond is usually more abundant or stronger on the margin of the fracture sustains this opinion.

In order that you may comprehend the difficulties fully in this case, where the fragments are not in actual contact, I must again call your attention to the fact that the synovia, always increased in quantity, presses up between the fragments, bathing the broken surfaces, and washing away the reparative material almost as fast as it is deposited. You will see that nothing but absolute and firm contact, such as will prevent the admission of the synovia between the fragments, can encourage a hope that the repair will be effected by material supplied by the broken surfaces themselves.

Let us not lose sight of the statement made in the opening of this lecture—namely, that a fibrous union is probably as useful as any bony union which can be obtained. No one has ever claimed that it is not easy to get a strong fibrous union where the original separation is not very unusual; and my purpose is to congratulate you on this fact, inasmuch as it is so difficult, and in most cases impossible, to maintain absolute contact and thus secure bony union.

Now we will consider some of the extreme, or, as they think, more certain expedients to which some surgeons resort to obtain a close bony union. Regarding a bony union as essential to the most perfect success or as required in order that the limb may hereafter be the most useful—an opinion which I do not entertain—they have sought to insure immediate bony union by the use of mechanical appliances which operate directly upon the fragments, and not indirectly through the integuments; with steel points or wire they propose to place the fragments completely under their command. Of which measures I affirm my belief that they have not in general, if ever, accomplished their purpose; that they are more or less dangerous to the limbs and lives of the patients, and that inasmuch as the other methods which insure a fibrous union, which will be as useful as a bony union, in all recent cases, are perfectly safe, surgeons cannot be well justified in adopting either one of them.

Let us first consider what is known as "Malgaigne's method," or the method of holding the fragments by metallic hooks. The instrument which I show you is the instrument invented and used by Malgaigne. His experience with these hooks, as related in his "Treatise on Fractures,"

is contained in four cases. (Although Druitt says, I do not know on what authority, that he had in 1858 treated eleven cases by this method satisfactorily.)

In two of these cases the hooks loosened and slipped, tearing the flesh and had to be removed after a short time. In one case, that of a boy eleven years old, the patella was *thought* to be united by bone; in one the union was thought to be partly bony and partly ligamentous; in one the character of the union is not mentioned, and in the fourth case, in which the hooks were not employed until after three months, the fragments were at first supposed to be united by bone, but it was soon found that no union at all had taken place. No evidence is presented that either of these patients had any more useful limbs than is usually obtained by other modes of treatment. Nor is there any substantial evidence that any of these had united by bone; no more indeed than is often presented after other methods of treatment, but in which the lapse of time or the autopsy has almost constantly proven that it was not united by bone.

I will now read to you what Malgaigne himself says of the value of bony union.

"On the whole, ossific union, taking place in the majority of cases with some separation of the fragments, the bone remains elongated and deformed; and I am not sure that this deformity does not interfere as much with the functions of the knee as union by fibrous tissue would. Boyer relates a case of this kind; the patella was elongated by about six lines; the patient was obliged to use a cane for a year, and thirteen years afterwards the flexion of his knee was still limited. I have myself published a case of bony consolidation obtained by M. Blandin; the increase in length of the patella was estimated during life at eight lines; at the end of the fourth month the leg could hardly be flexed five or six degrees. I sought in vain to find this man subsequently."

In both of these cases the bony union resulted in all but complete anchylosis. Certainly these examples do not argue much for bony union as compared with fibrous union.

Here is another paragraph which I will read you from Malgaigne; speaking still of bony union, he says "I have sometimes seen it myself, but what is very essential, never in simple transverse fractures. There was always at least one small splinter broken off from one of the fragments."

Speaking of the difficulty of adjusting and maintaining the hooks in position a long time, he says he has not been able to remedy it, and he alludes with his usual frankness to the cases of M. Roberts who failed completely with his (Malgaigne's) hooks to approximate the fragments; and finally he refers to one of his own cases in which, for some reason not stated, he removed the hooks and substituted pressure, "but the little wounds became inflamed, and erysipelas ensued."

Hear what Volkmann has recently said on this subject: "That Malgaigne's hooks, have caused ulceration of the joints and death of the patient in a number of cases, is only too true; I myself know of two which occurred in the practice of friends, and which were never published, and another sad experience met with in my own clinic a number of years since, of which I shall speak directly." Gross says they are apt to cause an erysipelatous inflammation. Erichsen speaks of their causing pain and irritation. Bryant says they are objectionable for the same reason. I have myself heard of a case in one of our city hospitals in which serious results followed the use of these hooks.

Agnew, in his excellent "Treatise on Surgery," has spoken very em-

phatically in regard to Malgaigne's hooks. I quote from the first volume, p. 980, of his recent publication.

"Once I have seen death follow the use of this infernal machine from an erysipelatous inflammation extending into the joint and giving rise to abscesses both within and without the articulation. No advantage whatever results from the close contact of the fragments accomplished by the instrument; it is rather a disadvantage, as the tendency to refracture is increased by the very closeness of the tension, the intermediate bond not being as strong as the ordinary fibrous tissue which fills the gap when the pieces of the bone are a short distance apart. Three times I have seen the union broken a few weeks after the patients treated by this method had been discharged from the hospital."

The only decided advocate of Malgaigne's hooks known to me in this country is Dr. R. J. Levis, of Philadelphia, who has modified the hooks, substituting two points for the four in the original instrument. The principle remains the same. In the *Medical and Surgical Reporter* for 1878, he has reported four cases, one of which was treated by Malgaigne's hooks, and the result was a separation of the fragments to the extent of half an inch. It is not stated that it united by bone, but he calls the result "good." The other three cases were treated by his own modified hooks. In one there is said to be "some separation"; one was refractured soon after he left the hospital, and in the third an abscess resulted which he thinks might have been due to the original injury. In one of the four cases the union is said to be ligamentous and in none is it declared to be bony.

Perhaps Dr. Levis has published other cases, but I cannot see in these four any thing to remove the prejudice which most surgeons, in common with myself, entertain towards this instrument. It is not sufficient for any surgeon to say that he has adopted this method in four cases without any disastrous results; nor indeed that he has had no mishaps in 20 or 25 cases. Other surgeons have met with them much oftener than this, and a method which exposes to suppuration of the joint, and death as a consequence solely of the apparatus employed, cannot be commended even if these results do not happen oftener than once in fifty cases; and especially when there is no satisfactory evidence that the average results are any better than by other and perfectly safe methods.

There are many other methods which have from time to time been suggested and practised, for the purpose of effecting a bony union of the fragments; a result which, you will remember, I have in the opening of my remarks to-day declared to be undesirable, and therefore certainly not to be sought for at the risk of life. Most of the plans I shall now refer to are in a greater or less degree attended with this risk.

Severinus, an Italian, proposed to make an incision into the joint, exposing the fragments, and then to freshen the broken surfaces and bring them together. This was nearly 300 years ago, when surgeons did not pretend to have any specific for preventing inflammation after wounds of large joints, such as Mr. Lister thinks we possess to-day. It certainly was a very bold or rather I would say a very foolish and reckless suggestion, and it is gratifying to know that he never practised it himself. It has, however, been actually done lately by Van der Meulin, Cameron, and Rose, with antiseptic precautions.

Dieffenbach is said to have cut the rectus femoris and ligamentum patellæ, the operation resulting in some improvement; but so good a surgeon and anatomist as he, ought to have known that the cutting of the

rectus femoris alone would not affect materially, if at all, the upper fragment. It would be necessary to cut the whole of the quadriceps; and to cut the ligamentum patellæ would be to substitute an ununited ligament for an ununited patella. The joint would in all probability be entered and the most disastrous consequences might ensue. Malgaigne doubts the faithfulness of the report of this case, and I doubt it also. Gould has more recently cut the quadriceps alone; at least we are told so, but I do not know the result.

Surgeons have occasionally, in the case of old, ununited fractures, introduced a tenotome subcutaneously and roughened the broken surfaces. This I have seen two or three times myself, but there has been no result whatever, so far as the union was concerned; nor is it probable, considering the peculiar conditions under which the fracture exists, that any benefit can be obtained from this expedient.

MM. Ollier and Goujon have recently injected fresh marrow cells between the fragments, and Dr. Wyeth, of this city, has repeated the experiment in old, ununited fractures; but neither of these gentlemen have obtained any results; nor do I very well see how they can reasonably expect any result, since the osteogenic materials must be placed, not actually between the fragments, for that would be in the joint itself, but only in the very thin tegumentary covering over the point of fracture.

Prof. Kocher, of Berne, Schede, and Volkmann, have recently advocated and practised opening the joint, with antiseptic precautions, for the purpose of letting out the blood, and for the purpose of securing bony union; but Kocher thinks this cannot be accomplished satisfactorily when the blood has become coagulated. He advises, therefore, that it be done immediately, or as soon as the fracture comes under the surgeon's observation.

The objections to this method are, first, that it is dangerous despite antiseptic precautions; second, that blood in any considerable quantity is seldom effused into the joint; third, that we can never be sure of being able to remove any but a small portion of the blood; fourth, that even if successful, we have in only a slight degree removed the obstacles in the way of bony union; and finally, that bony union is not desirable. As to the danger of suppuration from the presence of blood in the joint, I have not in a very large experience seen such a result from such a cause. Yet I can conceive of a case in which the extravasation may be so great as to render the evacuation of the blood advisable to prevent suppuration. But such cases must be exceedingly rare, and considering all the objections which exist, you will probably do better if you never adopt the suggestions of these gentlemen. There is more danger in this indiscriminate opening of joints than in omitting to open the few cases in which it might possibly prove serviceable.

I think it was Schede who first proposed and practised, for the purpose of effecting bony union, introducing a large needle, armed with a silver wire, through the joint; introducing it below the lower fragment, and bringing it out above the upper, and then drawing the fragments together. The operation being done antiseptically. He says he has done it three times and obtained bony union—a statement, the correctness of which Kocher ventures to doubt.

Kocher has modified this operation by first making incisions through the skin, above and below the fragments, and then introducing the needle and silver wire. He says he has done this twice, but he confesses that he

did not prevent separation of the fragments, and he does not pretend that the union was bony.

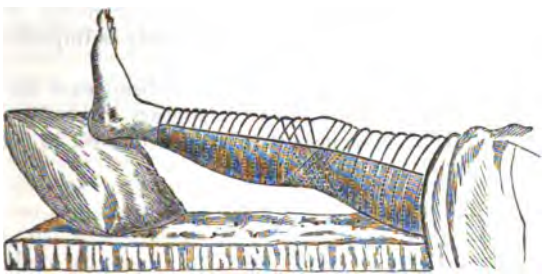
Volkmann, as I have already told you, confesses to having had a sad experience with Malgaigne's hooks, still however seeking for some mode of obtaining bony union he has employed what he calls the "tendon suture." A common ligature was passed through the tendon of the quadriceps and of the patella, and by these means he tied the fragments together. In one case he thinks he had bony union, in one a "satisfactory result," in one it was "all that could be desired," and in one the patient died! Although in this case the ligature was in place only one quarter of an hour, but the ligature had, as the autopsy showed, penetrated the joint.

Such are some of the expedients for the purpose of procuring bony union to which surgeons have from time to time, and especially of late, resorted. I confess, gentlemen, it does not increase my respect for the judgment of surgeons who adopt any or most of these methods. Their performance does not exhibit simply a rudeness of conception as to what it is desirable to accomplish, but some of them an absolute lack of appreciation of danger in surgical operations. They seem to me to be the devices of mechanics and not of surgeons.

Dr. Hamilton's Method of Treatment.—In nearly all cases the adjusting retentive apparatus may be applied at once. If exceptions occur it will be in those cases in which the patella has suffered from a direct and severe injury, and the swelling and tenderness are unusual. The single inclined plane recommended by me in the earlier editions of my work on "Fractures and Dislocations" I now very seldom use. It is in all respects sound in principle, but it is unnecessarily cumbrous for ordinary cases. A light splint and a cotton roller are the only essential parts of a proper apparatus.

Here is a patient to whom this dressing has been applied. The best materials for a splint now known to me, in the case of a fracture of the patella, is gum shellac cloth, made of about six thicknesses of cotton cloth saturated with gum shellac. It is made by the hatters, and can always be obtained from the instrument makers in this city at a moderate cost. The same material can be used for splints in the case of most long bones. It is not patented. The splint must be long enough to extend from above the middle of the thigh to near the ankle, and wide enough to envelop half the circumference of the limb. This being moulded to the back of the limb, must be covered by a complete sack of cotton or woollen cloth, after which it is to be laid against the back of the limb; and first a roller is applied just below the knee by several circular turns, including both splint and leg; second, the roller is carried obliquely above the patella, and then around the limb and splint in a circular manner. In short, by oblique and circular turns the fragments are to be gradually drawn together—the integument being meanwhile, as far as possible, kept from doubling itself between the fragments—and the oblique turns gradually approaching each other in front of the patella until the whole is covered in. Third, a separate roller is applied to the lower part of the limb and splint, and a third to the upper part. Fourth, all the turns of the rollers are carefully stitched to each margin of the cover of the splint. Fifth, the limb is laid in bed with the foot resting upon a pillow so as to raise the foot about six inches. If you deem it necessary, the foot may be secured in this position by some permanent apparatus, or by being placed in a swing; only that the importance of keeping the foot permanently elevated during the first two or three weeks must be recognized.

The limb must be examined daily, and as soon as the bandages about the knee have slackened from the subsidence of the swelling or from any other cause, with a large needle and strong linen thread, they must be tightened by overstitching; and especially must the oblique turns which pass above and below the fragments be thus tightened. This may have to be repeated every day for several days, but it will seldom be found necessary to remove and reapply the bandages within the first two or three weeks. At the close of the second or third week the dressings should be removed and the limb examined, when it will generally be found that the upper fragment is nearly or quite immovable, unless considerable force is applied; it is therefore no longer liable to be drawn up by the ordinary action of the rectus or quadriceps, and we can give to the joint a little motion without in any degree increasing the separation of the fragments; but to avoid all danger we may press down the upper fragment while we move the joint gently.



The same dressings are then to be reapplied and with the same care. From this time forward there can be no objection to the patient's being about on crutches, since the anchylosed or semi-anchylosed condition of the upper fragment will prevent its being influenced by the ordinary action of the rectus; but regularly at night, or at least every second day, the splint should be removed and slight passive motion employed.

Ordinarily we may discharge the patient at the end of six or eight weeks from our immediate care, but with instructions to continue to wear the splint or some equally firm substitute eight weeks longer. It may be removed, however, whenever he is in bed. The necessity of wearing the splints so long is found in the great frequency of refractures during the first month or two after the dismissal of the patient; that is to say, after the splint has been removed, and within four months from the date of the receipt of the injury. Laced or elastic knee-caps do not give the required support; they give way under any considerable strain upon the joint, as experience has shown in several instances. And the same accident would be just as liable to occur if the fragments had united by bone, or even more so. Remember that we cannot apply the same rules here that we do in fractures of long bones. When these latter bones have united, and the limbs are put into use, the point of fracture is not subjected to the enormous cross-strain to which united fractures of the patella are subjected —I speak particularly of fractures of the shafts of long bones—and we can generally permit these patients to go about safely without splints at the end of eight weeks. It is very different, as you must see, with the patella.

Please, gentlemen, remember all the details of the treatment which I have recommended to you. They all contribute to the best results, and

no one of these details can be safely omitted. If you wish to avail yourselves of the results of my experience, you must follow minutely my directions. Do not use compresses, or adhesive strips, or elastic bands, or metallic, or other hard adjusters, or plaster-of-Paris, or any other form of immovable dressings. Do not let the patient get up on crutches in less than two or three weeks. I have good reasons for advising you thus, some of which I have given, and others of which I have not time now to give. Avoid every method, whether new or old, which endangers in any degree the limb or the life of the patient, since there is before you a simple and perfectly safe method, which assures to your patients as good and probably better results than the dangerous methods.

There is one thing more which I had almost forgotten to say: when, at the end of four or five months from the time of the original injury, the splint is wholly laid aside, do not apply a knee-cap or any bandage to the limb, but let the patient use the muscles of his leg freely, so that they can recover their normal strength and size. It is surprising how much the ability of flexing the limb and to sustain the body is improved under free and unrestrained use of the muscles.

The anchylosis of the upper fragment soon disappears under use; and the anchylosis of the knee-joint itself disappears gradually, in the same manner. Under no circumstances is it proper to seek to overcome it by force.

ABSTRACT OF A CLINICAL LECTURE ON THE TREATMENT OF SOME FORMS OF EPILEPSY.

Delivered at the Hospital for Epilepsy and Paralysis.

By J. S. RAMSKILL, M.D. Lond.,
Junior Physician to the Hospital, Consulting Physician to the London Hospital.

Gentlemen: The boy I show you (L——) says he is eight years of age, and that he has been ill eight months. He looks his age, and is fairly intellectual. He had been at school for five years before the accession of the fits. The shape of his head is good, and there is no particular vaulting of the roof of the mouth. I always examine the mouth both with a view of ascertaining the height of the roof and the state of the teeth, both as regards caries and overcrowding. About the age of puberty the latter condition is not a very rare cause of epilepsy. And it is always well to exclude every source of irritation arising from that most reflex nerve of the body, the trigeminus.

We have no neurotic family history, and no account of any previous illness to note. Examination of the heart and lungs reveals nothing, neither does the ophthalmoscope. The abdomen seems full, some gurgling sounds are heard on palpation, and it is more doughy than natural; but on account of a certain amount of superficial fat, the state of the colon and viscera can hardly be made out. Now, about a month before the commencement of the fits, the boy complained of a bad cramp in the left wrist and upper half of the hand. In remained only a few seconds, but recurred at different intervals: sometimes twice or three times a day, and next day only once. About the end of a month he was knocked down by a blow on the left side of the head. He did not lose consciousness, nor was he sick, neither had he subsequent headache.

Next morning he had a fit, and several during the next fourteen days; then he was free for a month. They then returned, but only by night; but during the following month they came both by night and day. We learn from the parents that the character of the fits is as follows: He first has the cramp in the left hand and wrist, screams, and also, sometimes, bites his tongue; is universally convulsed, but most so on the left side. The fits last only a few seconds. He occasionally has one in the day, but usually eight or ten every night. It is observed that if he falls asleep during the day he has a fit. There are no sequelæ of note to the attacks.

Such is the aspect of the patient and the history of the case. The first point to decide is this: Is the patient epileptic? and, if so, is the disease idiopathic and primary, or is it secondary or sympathetic? It would be waste of time to argue the first question. The case is clearly epileptic; but it is quite a question as to whether it be idiopathic or not. Modern science would at once say it is centric, and the particular part of the brain most involved was the right ascending frontal convolution, an explosion from which spreads upwards, downwards, and backwards, involving an area which might be mapped out by the presence of convulsion or spasm in the muscles engaged. The aura does not consist of an irritation going to the brain, although a ligature above its seat may stop the fit. You all know aura may exist with some coarse centric disease, and a ligature may still stop the accession of the fits. This, I say, is the received opinion; but I am not sure of its universal truth, especially with regard to unfelt aura, which we must suppose to exist. An unfelt aura seems a contradiction in terms; but it is not so, for, as far as I can make out, in the case of a patient who one day has a fit with an aura, and next day another of exactly the same extent and character without any, there must have been a similar, or the same, cause in both.

I think, perhaps, the explanation lies here, that the spread of the discharge was too quick, that the patient had not time to perceive the aura before the attack became general, or before consciousness was lost. But we find on examination the boy has often the aura without a fit. Then I look on his aura as a fit—a minor and localized one. A greater question to my mind is this, Are not most epilepsies eccentric rather than idiopathic and centric at first? Does the existence of an aura really settle everything? Neither physiology nor pathology helps us, but I think practice can. If you prevent both aura and fit, by slight treatment, which cannot reasonably be presumed to have any influence on the cerebro-spinal centres, it is a fair supposition that the cause is not centric, but originates within the sphere of action of your treatment. But I do agree to this opinion, that eccentric soon passes into centric idiopathic epilepsy, or perhaps, that you may, after one has generated the other, have both forms of disease in the same subject. Be this so or not I am inclined, and I dare say you are, to say with the celebrated Trousseau, "Good heavens, gentlemen, a little less science—a little more art." The question then is what line of treatment shall we pursue. This is the programme we adopted.

(*a*) To see if we could find any source of irritation in the abdomen, "for of all the regions of the body there are none which reflect more strongly on the brain than the intestines and visceral organs."

(*b*) To give what remedies we know are able to allay the reflex excitability and force of the cerebro-spinal centres.

With the first object in view, vermifuge aperients, santonine and castor-oil, is the usual combination for children, to be given sufficiently long to make sure of the result.

In our case the result was *nil*. Had a worm been expelled the fits might have vanished; but this is not the rule, unless your treatment has commenced very early

in the case after the first attacks. The lumbricus may be dislodged, but the central excito-motor region has taken on morbid action, and the epilepsy remains. Still, in these cases, I always think there is most hope, and most room for treatment; for if the irritation of a lumbricus could by a certain route in the nervous system produce a morbid result on the centre, some remedy acting through the same route may lessen, deaden, and finally stop that morbid process in the same centre.

Let us continue our examination of the abdomen. I want to know the condition of the colon. We have found the abdomen full—that is, tumid, bigger than it should be, but, without chloroform, we cannot make out anything beyond gurgling.

By the light, then, of experience we make the assertion, that there is probable defect of the colon, as to secretion, spasm, contraction, and alternate dilatation of its calibre. In a post-mortem of an epileptic by Vanderkolk he says: "We found in the abdominal cavity the colon and sigmoid flexure very much dilated and lengthened, the latter ascending to the transverse colon. Above and beneath the sigmoid flexure were many constrictions, which higher up alternated with dilatations; the cæcum, too, was very dilated." This is a severe case; but one cannot help observing in the records of post-mortems the frequent occurrence of a strictured and dilated colon.

What cases of mental depression, of melancholia, have we not all seen associated with loaded, and probably sacculated, colon! In one series we seem to get an irritant; in the other an inhibitory action on the nerve centres. I recollect an old practitioner saying (before the advent of bromide) that a daily morning dose of beaume de vie was of more service in epilepsy than all the medicines in the Pharmacopœia.

To recur to our patient, we kept him in the hospital ten days without treatment, beyond the prelude of aperients, to see his exact condition as to the kind, number, and duration of the fits.

On Oct. 13th he had 5 fits; 14th, 7 fits; 15th, 15 fits; 16th, 13 fits, and one in the afternoon, when he had fallen asleep; 17th, 9 fits; 18th, 6 fits; 19th, 7 fits; 20th, 15 fits; 21st, 9 fits; 22d, 15 fits. The fits turned out as described. On Oct. 23d we ordered thirteen grains of bromide of potassium, three grains of iodide of potassium, and eight grains of carbonate of ammonia, three times daily, with this result: Oct. 24th, 9 fits; 25th, 7 fits; 26th, 11 fits; 27th, 9 fits; 28th, 13 fits; 29th, 9 fits; 30th, 9 fits; 31st, 10 fits. The same rate continued until Nov. 4th, when we added more ammonia in the shape of ammoniated spirit. The rate began to diminish, as for the consecutive days we got 7, 6, 6, 7, 2, 8, 6, 5, 6, 5—plus one in the day—then 5, 6, 9, 5, and about the same rate until Nov. 27th. On that day a mixture of equal parts of chloral, camphor, and vaseline was ordered, a portion equal to a small teaspoonful was to be rubbed into the scalp every night. The mixture of bromide, iodide, and ammonia, to be continued, and a pill containing equal parts of aloes, valerianate of zinc, and extract of conium, given every night.

The result of this treatment was, that we had no recurrence of fits of any kind for more than five weeks. Then we had one fit each night for three nights, and I confess that I was glad to see them return. Vanderkolk quotes some cases showing the danger to life which may arise from the prolonged freedom from fits. And, as a general rule, it may be said that in chronic epilepsy the longer you manage by treatment to prolong the interval between the attacks the more severe the following fit will be. Death occurs from asphyxia or from congestion of lungs and coma. It is astonishing that apoplexy is not frequent, but to me it is simply unknown as a result of the most violent and prolonged attacks.

I have had experience only of three fatal results; all occurred after a so-called cure had been made; all in the night, and the patients were found dead in the morning. What I wish you to remember is that after a prolonged interval of freedom you must apply some counter-irritant, such as a seton, issue, or leeches, to prevent or to break a too violent explosion.

To return to our case, To what is the improvement due? What is the rationale of the action of the means employed? Perhaps we should do best to see these points illustrated in another case.—*Lancet*, Feb. 26, 1881.

Hospital Notes.

Bellevue Hospital, New York.

(Service of Dr. Austin Flint, Sr.)

Acute Articular Rheumatism. Treatment with Salicin and Alkalies.

(Specially reported for the Medical News and Abstract.)

Robert C., æt. 26, Irish, porter; admitted Feb. 22, 1881. The patient confesses to the occasional excessive use of alcoholics. He has been employed in the kitchen of a hotel, where he was subjected to frequent alternations of heat and cold. On Feb. 18, he was attacked with acute pain in his left ankle, accompanied by heat, redness, and considerable swelling. The right ankle was next attacked and both knees, both shoulders and the fingers of both hands were subsequently, successively, involved in the inflammatory process. On his admission, Feb. 22d, all the above-named joints presented the signs of acute inflammation. A soft, blowing systolic cardiac murmur was heard at the apex, and was not transmitted to the left. There was no cardiac enlargement. Temperature 103°, pulse 98, respiration 28. Inasmuch as the blowing endocardial murmur was regarded as the evidence of endocardial inflammation it was decided to employ salicin rather than salicylate of soda. Two-hourly doses of salicin, grs. xx. with acetate of potassium, grs. xxx. were prescribed. No other remedies were administered. At the beginning of the treatment the urine was acid and high coloured, with a specific gravity of 1032. It contained no albumen and no sugar.

Feb. 23d. Pain in the joints has been considerably relieved. The urine still remains acid. Temperature, A. M., 103°; P. M., 102¼°.

24th. The pains, redness, and swelling of the joints have markedly diminished. The urine is alkaline. Temperature, A. M., 102°; P. M., 102°.

25th. The joint symptoms have almost disappeared. The urine is alkaline. The cardiac murmur still persists. No pleuritic or pericardial complications have appeared.

March 1st. The acute inflammatory symptoms have disappeared. The temperature has remained at about 100° since the last note. The alkali is now discontinued, but the salicin is still administered, as before, and has occasioned no gastric disturbance.

3d. All febrile symptoms have ceased. Temperature 98½°. Only slight stiffness of the limbs remains. The cardiac murmur is indistinctly audible.

Hystero-Epilepsy; Phases like those described by Charcot; Obstructive Dysmenorrhœa; Treatment by Dilatation of the Cervix Uteri.

A fairly intelligent Roman Catholic aged twenty-one was admitted into Dr. Sansom's ward in the London Hospital, on Aug. 20th, 1880. She lived from the age of thirteen to seventeen in Canada. Her mother's father died of consumption, but there was no neurotic family history. As a child she had good

health, but whilst in Canada, and even after, she had suffered much from headaches, and from frequent attacks of vomiting. She first menstruated at the age of eleven; had always been very irregular; her menses were scanty, lasting never more than three days, and always accompanied by severe pain, both constant and paroxysmal, referred vaguely to the back and to the front of the abdomen, and coming on at the commencement of the flow, and lasting till it ceased.

She was first taken with fits in April, 1880, in which she lay for about five minutes in a rigid condition, and with her eyes shut. She at the same time had great impairment of memory. These fits came on about once a day on an average till the middle of July, when they became much more frequent, and of a more violent character.

She had five fits on the first day of admission, lasting from a quarter of an hour to an hour, and several similar fits on many days following. A fit could at any time be excited by pressure on the ovaries, and during its manifestation pressure on the ovaries would either arrest it or alter its character. Pressure on other parts of the body did not produce a fit. They were most frequent about the time of a menstrual period, and she also seemed to be more liable to them after being visited by the priest. Between the fits she seemed cheerful and intelligent, but suffered a good deal at times from headache, which, she said, felt as "though nails were being hammered into her head."

The fit consisted of a series of stages: 1. They began by her head being thrown up, and inclined slightly to the right, while her eyes were turned up and to the right, and her mouth widely open. Her limbs were placed in a position approaching that of crucifixion, her legs extended and lying together, while her arms were held out straight nearly at right angles to the trunk, her fingers being over-extended, bent back towards the dorsum of the hand. 2. After lying quite still in this position for a short time she began to make lateral and to-and-fro movements with the tongue, and to froth at the mouth (she never bit her tongue). Her head began to move slightly from side to side, then more violently, till at last her whole body was implicated in a violent side-to-side movement. 3. These movements were soon exchanged for violent and extreme extension and flexion of the trunk; at one moment she bent forwards so that her head almost touched her feet; the next, threw her head violently back on to the bed. 4. She then again assumed the crucifixion position, and on some occasions arched her back in a rigid opisthotonos. 5. Finally, she drew several long breaths, her limbs relaxed, and she turned on to her left side, placed her hand over her heart, and began to cry; she then sat up, smiled, and said she felt tired and weak. During the fit the corneæ were insensitive, and pricking her with a pin caused her no pain in any part of the body.

Treatment was directed to the relief of the dysmenorrhœa, which Dr. Herman considered to be due to a narrow cervix. On Sept. 27th bougies Nos. 4 and 5 were passed; their passage excited a fit. On Oct. 5th bougies Nos. 6, 7, and 8 were passed; a fit again occurred. On Oct. 18th bougies Nos. 8, 9, and 10 were passed; a fit occurred afterwards. She at the same time took one grain of valerianate of zinc three times a day. Her fits soon began to diminish in frequency, till by the middle of October she did not have more than two a week. Her menstruation also became easier, and the pain was much lessened. Pressure on the ovaries produced much less effect. She menstruated on Nov. 30th and Dec. 1st without pain for the first time in her life. She had no fits after that, and when she left the hospital on Dec. 7th she had not had a fit for more than a month.—*Lancet*, March 5, 1881.

MONTHLY ABSTRACT.

Anatomy and Physiology.

The Vessels of the Retina.

Professor His, in the third part of his *Archiv* for 1880, gives an interesting description of his observations upon the distribution of the vessels in the retina of man and some animals. He makes this communication *à propos* of a paper by Dr. Hesse, who has demonstrated the existence in the retina of the rat of an internal arterial and an external venous layer of capillaries. Professor His depicts the arteria centralis in man as running in the nervous fibrous layer, and giving off from either side lateral capillary branches, which he names the arteriæ afferentes. These leave the main trunk almost at right angles. After a short course they divide and subdivide dichotomously, and form a tolerably distinct network of arterial capillaries, the individual vessels passing in and out through the spaces of the inner granular layer, where they form the deeper-lying or more external venous plexus. These, again, transmit the blood they contain into the venæ efferentes. The arteria centralis retinæ possesses a muscular tunic whilst it is still imbedded in the optic nerve; but this coat becomes thinner as the artery approximates the lamina cribrosa, and loses itself after the artery has traversed that lamina. In the retina itself the arterial branches are surrounded by a tunica adventitia, which gradually becomes thinner. There are no horizontally running capillaries in the molecular layer. All the vessels here have a radiating direction. Another point which he believes he has made out, though he is not quite certain, is that the portion of the optic nerve which is situated distally to the lamina cribrosa is provided with a very close network of large capillaries.—*Lancet*, Feb. 26, 1881.

The Atrophic Lines on the Abdomen in Pregnancy.

The appearance of silvery, riband-like streaks on the abdomen, the result of atrophy of the skin, as a result of stretching of the integument, after pregnancy, or distension of the abdomen otherwise brought about, is not merely familiar to medical men, but to patients; and the minute anatomy and conditions of origin of this change have been pretty well worked out, thanks chiefly to the labours of Credé, Schultze, and Hecker. Drs. Krause and Felsenreich have investigated them from a new point of view, viz., as an index of the tension of different parts of the abdominal wall, and a measure of the degree to which they regain their former state when that tension is removed. The best anatomical researches into this form of atrophy of skin which had been made previously are those of Küstner. He has shown that the change is often not merely in the epidermis, but that there is a solution of continuity in the deeper layers of the skin also. At the lines of atrophy, the cells of the horny layer of the epidermis are arranged more in rows which are regularly transverse to the course of the atrophic striæ than in the healthy integument; and the minute depressions and elevations of the natural skin are here smoothed out. Länger has also investigated the subject, and has shown that the bundles of fibrous tissue, which in the reticular layer of the normal corium cross one another so as to make the interspaces between them rhombic in shape, run transversely and nearly parallel to one another, across

these atrophied parts. The papillæ also are here set in transverse rows; but if the band be a broad one—that is, if the stretching have been considerable—they may be so distant from one another as to make it difficult to perceive what is their arrangement. The bloodvessels also run transversely, instead of forming the usual network.

This was the state of the subject when Krause and Felsenreich applied themselves to its further investigation from the point of view we have indicated. They took as the field of their researches women pregnant for the first time, because in them the changes due to stretching of the skin would of course be seen at their maximum. Their method was this. They used a wooden stamp to imprint upon the abdomen a circular mark about an inch in diameter. The marks were made with aniline blue, which, after a trial of many other pigments, they found to be that which would best and longest resist friction and moisture. Being made with a stamp, the marks were of course all exact in shape and equal in size. A circle was marked, having the umbilicus as its centre; and from this as a starting-point rows of circles were imprinted, running up to the ensiform cartilage down to the symphysis pubis, transversely from side to side across the abdomen, and obliquely on each side to the right and left anterior superior iliac spine. These marks were made before labour; and on the ninth and tenth day after delivery (this day being taken because it was the last of the patients' stay in hospital) they were again examined. The diminution in size of these circles showed, of course, the amount of contraction of the skin at each place, and the alteration in their shape the direction in which contraction had occurred. The first thing found was that the post-partum contraction was not regular; the vertical row of circles, instead of being, as when made, a perfectly straight line, now was undulating and zigzag. The amount of shortening of the line connecting the umbilicus with the symphysis pubis was from half an inch to two inches; of that joining the navel to the ensiform cartilage did not amount to more than half an inch. The lines going from the umbilicus to the iliac spines were at most only shortened an inch, and there was often more than half an inch of difference between the two sides, even when before labour their length had been identical. The diminution in the circumference of the belly at the umbilicus varied from about five to seven inches. By comparison of the circles forming the lines mentioned it was found that along each line the amount of post-partum contraction of the skin increased as the umbilicus was approached. It was greater along the lines radiating from the umbilicus than in the direction perpendicular to them. An exception to this, however, has to be made in reference to the linea alba, in which the contraction was less in the vertical than in the transverse direction. A comparison of the circles showed that, although the contraction of the linea alba above the umbilicus was less than that below, yet that in other parts of the abdominal wall there was more contraction above than below the navel—a fact which the authors suppose due to the great stretching of the parts below the umbilicus having deprived them of their elasticity. It results from these observations, that above the umbilicus the contraction of the abdominal walls after delivery is greater in a direction transverse to the linea alba than parallel with it, the direction of maximum retraction being a line running downwards and towards the linea alba. At the level of the navel the contraction takes place towards that point; and below this line the direction of its maximum is indicated by a line running upwards and towards the linea alba. The reason why the contraction is less in the direction of the linea alba than transverse to it is a simple one. It is this: that such contraction is effected by the fibrous bundles coming to cross one another at more acute angles. In the linea alba the fibrous bundles are already nearly parallel, and therefore there is little room for this change to take place. According to Länger,

the fibrous bundles of the skin of the abdomen form rhomboidal meshes, the long diameter of which is parallel with the ribs. It will be seen that the statement of Länger explains the changes observed by Krause and Felsenreich.

Immediately around the navel contraction takes place equally on all sides and towards that point. The course of the atrophic lines is this. Near the linea alba they run parallel to it. Close round the umbilicus (over the area in which contraction takes place uniformly towards it) they form a confused network around that point, striæ crossing one another in all directions and at all angles. Further outwards they run concentrically around the navel. Comparing the course of the striæ with the lines described as those of maximum retraction, it will be seen at once that the former are at right angles to the latter. The atrophic striæ therefore indicate the directions in which, during pregnancy, the greatest tension has been put upon the abdominal walls.

So far as the particular facts themselves go, which Krause and Felsenreich have thus ascertained, they are not of much practical moment. The chief interest and importance is that which they suggest, viz., the relation between the lines of greatest tension, the direction of the atrophic striæ, and the texture of the tissues concerned. It remains to be seen, by equally careful examination of other parts, whether similar conditions in other parts of the body are the result of the same concurrence of causes.

The work of Drs. Krause and Felsenreich is an example of that patient labour bestowed upon apparent trifles, for which we so often have to thank our German brethren. Unimportant as they may seem to the self-styled "practical" man, investigations like these yet fill crevices in the edifice of scientific truth, and are of more value than nine-tenths of the literature which is concerned only with the production of so-called "cures."—*Med. Times and Gazette*, Jan. 29, 1881.

Materia Medica and Therapeutics.

The Antagonism of Atropia.

Dr. Roberts Bartholow, in his third Cartwright Lecture, summarizes the conclusions of his studies upon the antagonisms of atropia as follows:—

Antagonism of Atropia and Physostigma.—1. That physostigma or eserine, and atropia are antagonistic in their effects on the pupil. 2. That they act differently, but probably not antagonistically, on the heart, unless we accept the views of Köhler and Bezold and Bloebaum—the former maintaining that physostigma paralyzes the accelerator nerves of the heart, and the latter that atropia stimulates these nerves. 3. That they are opposed in their action on respiration, physostigma paralyzing, and atropia stimulating, the respiratory function. 4. That they are not opposed in their action on the cerebrum, atropia producing delirium, and physostigma having no effect on the cerebral functions, while both cause more or less carbonic-acid narcosis. 5. That they act differently and not in an opposed manner on the spinal cord and nerves, both producing paralysis, but atropia does, and physostigma does not, impair the irritability of motor nerves. As regards the sensory nerves, physostigma augments their irritability, while atropia seems rather to lessen it, if any effect is produced. 6. That they act oppositely on secretion, physostigma stimulating and atropia arresting the secretions in general.

It follows from these conclusions that the lethal effects of physostigma, due to paralysis of respiration, are overcome by atropia by sustaining the respiratory function. The Committee of the British Medical Association assert that "the

antagonism exists within very narrow limits," but this happens to be sufficient to avert death, when doses little more than lethal have been administered; still, the use of physostigma against the lethal effects of atropia is of doubtful propriety. The paralyzing effect of physostigma on respiration may, doubtless, be successfully overcome by the suitable application of atropia.

Belladonna and Pilocarpine.—Belladonna and pilocarpus are antagonistic in their action: 1. On the secretions, especially of sweat and saliva, pilocarpus promoting, and belladonna arresting, them. 2. On the heart and arterial system, pilocarpus slowing and enfeebling the heart and depressing the vascular tonus—belladonna stimulating the cardiac movements and raising the arterial tension. 3. On the eye, pilocarpus contracting the pupil, inducing spasm of accommodation, and approximating the nearest and most remote points of vision—belladonna dilating the pupil, paralyzing accommodation, and making the vision presbyopic.

On the brain there is no real antagonism. The excitement, the delirium with hallucinations and illusions, and the subsequent coma, caused by atropia, are not affected by any of the actions of pilocarpin. The soporose state brought on by the latter, as I have pointed out, is a secondary effect, the result of exhaustion and cerebral anæmia.—*New York Med. Journal*, Jan. 1881.

—

Physiological Action of the Active Principle of Piscidia Erythrina—Jamaica Dogwood.

Dr. Isaac Ott, describes (*Archives of Medicine*, Feb. 1881) some experiments which he has lately performed to ascertain the physiological action of the Jamaica dogwood—a drug which has recently been introduced as a narcotic.

His conclusions are—

1. That piscidia (the active principle) is a narcotic.
2. That it does not paralyze or excite the motor nerves.
3. That it does not act on the extremities of the sensory nerves, but their central connection—the sensory ganglia of the spinal cord.
4. That it produces convulsions, partly by stimulation of the spinal cord and partly by heightened excitability of the voluntary striated muscles.
5. That it reduces the frequency of the pulse by an action on the heart itself, probably on its muscular structure.
6. That the arterial tension temporarily rises by stimulation of the monarchical vaso-motor centre; that it soon falls, due to a partial paralysis of this centre and the heart itself.
7. That it at first contracts and then dilates the pupil.

—

On the Catgut Ligature.

Upon the occasion of his taking the Presidential chair at the Clinical Society at London, Mr. Lister delivered the following address on the catgut ligature, which is full of interest for every practical surgeon. He said:—

The catgut ligature has in some respects exceeded my original hopes. I feared that its advantages would be limited to wounds in which putrefaction was avoided, and that if septic suppuration took place in a wound in which it was employed for securing the vessels the ligature would sooner or later come away like little sloughs. Such, however, has not proved to be the case. Whatever be the progress of the wound, we never see anything of the catgut, so that even surgeons who have not adopted strict antiseptic treatment have been led to employ the new material in ordinary wounds. Under other circumstances, however, the catgut has often led to disappointment. We hear of cases in which Cæsarean section

has been performed, and all has gone on well until the knots of the catgut with which the uterine wound was secured have given way, and the patient's death has been the result. Again, in ligature of large arterial trunks in continuity several surgeons have met with bitter disappointment, the case ending in disaster from secondary hemorrhage or the treatment proving abortive through the channel of the vessel becoming opened up again at the site of the ligature. Hence many surgeons have been induced to return to silk, even though using strict antiseptic treatment, rendering the silk aseptic by steeping it in suitable lotion and cutting the ends short. This practice has, however, by no means proved uniformly successful. As an instance of unsatisfactory result, I may mention a case which was recorded by Mr. Clutton in the last volume of our *Transactions*. He tied the external iliac artery under strict antiseptic precautions, and the wound healed within a week; but, as I learned from a letter which he was good enough to send me at the time, six weeks after the operation a little blister formed and fluid began to escape, forming a small scab, and in three months the loop which had been placed around the artery came away. Such a result was not at all surprising to me, seeing that what induced me to try the animal ligature was the discovery of a small abscess about the remains of a partially absorbed silk thread which I had applied in the same manner as Mr. Clutton, and, as it so happened, to the same artery. It can hardly be doubted that suppuration proceeding from the immediate seat of the ligature must be a source of danger. As an illustration of the mischief which a ligature of ordinary material may do, I may mention a case of goitre in a young woman on which I operated on January 28 last year. It was of moderate dimensions, but the effect on the respiration was considerable, and I determined to operate by Dr. Patrick Heron Watson's plan of preliminary deligation of the thyroid vessels circumferentially to the tumour (if this is effectually done the operation is bloodless); so that, as the laryngoscope, applied by Dr. Felix Semon, who had recommended the case to my care, showed that the trachea was pressed backwards considerably by the growth, I adopted a measure which I believed would, in all cases of removal of the thyroid, prove advantageous—namely, I divided the tumour in the first instance in the middle line, so as, in the case of adhesions to the trachea, to be able to remove the two halves of the growth at leisure, to dissect it off from the trachea. But in order that the carbolic ligature may be secure it is essential that the material should be very strong, so that the tissues round about the tumour, including the vessels, may be securely tightened up. I possessed no catgut which I felt was strong enough to bear the full strength of my hands, and therefore I was compelled to use the hempen ligature, after of course carefully rendering it antiseptic by means of the carbolic lotion. Six of these hempen ligatures were used—three on each side. During the first eight days everything went on in a typical fashion according to the antiseptic method. There was a small serous effusion rapidly diminishing, and we looked to the wound being healed in a few days more; but on the ninth day there was seen to be a little something of a purulence mingled with the discharge; the pus became thicker—always in small quantity; a small quantity could be pressed out from each side. In a month one of the hempen ligatures made its escape. In six days more four other of the hempen ligatures came away altogether unaltered, as may be seen on the table, where I have exhibited the hempen ligatures which came away from this case. I submitted them to careful examination. They had a sour odour, and, applied to litmus paper, gave an acid reaction—that is to say, the natural alkaline reaction of the blood-serum had been changed to acidity by some peculiar species of fermentation, inasmuch as putrefaction would have, if possible, made the blood-serum still more alkaline. On examining them with the microscope, I found the interstices of the threads of the

hemp loaded with a little organism, to which I believe I happened to be the first to direct attention as to its mode of growth, and to which I gave the name of granuligera, occurring in groups of twos, threes, fours, and so forth, as distinguished from the chains in which ordinary bacteria occur, and of which one form at least has been since shown by Mr. Cheyne to occur very frequently in cases treated antiseptically without any interference with the antiseptic process. I found that the interstices of the threads of the hemp were leaded with these little micrococci. It so happens I have had an opportunity within the last few days of obtaining a sample of these micrococci, thanks to Mr. Cheyne's kindness. He brought this bottle of a pure and perfectly transparent infusion of meat to a case which I had operated on a fortnight before by excision of the ankle. The skin was unbroken; we were able therefrom to operate antiseptically. The case pursued a perfectly typical course. The wounds, which were left gaping at the time of the operation, were filled with blood-clot, which remained unaltered in appearance, though undoubtedly becoming organized by that time—more or less. A little piece of the blood-clot from one of these wounds was introduced with careful antiseptic precautions into the flask of clear fluid, and you will see it is now turbid. But though, under ordinary circumstances, these micrococci may be present—as Mr. Cheyne has abundantly shown, and as the case I have referred to illustrates—without causing any evil, yet there may be circumstances in which they may prove mischievous, and the case which I have been relating appears to have been one of these. The micrococci developing in the interstices of the hempen ligature produced an acid fermentation of the serum in its most aggravated form. The acid serum became a cause of irritation, and thus the ligatures which otherwise being unirritating would have been capsuled, and in due time absorbed, became causes of suppuration. One of the six ligatures still remained unaccounted for. In due time we sent the patient home with a small sinus remaining, a little pus always discharging from it; but it was not until the middle of September last that the last ligature came away altogether unaltered. Now, gentlemen, there is no doubt whatsoever that if I had had a ligature of catgut which I could have trusted for the operation, the catgut ligature would have been disposed of within two or three weeks. Here, then, we have an illustration of the great disadvantage which may arise, even under antiseptic treatment, from the use of the ordinary forms of ligature.

Animal ligatures of another kind have been provided by Mr. Barlow in order to remove these difficulties, namely, strips of the mingled yellow elastic and unstriped muscular tissues which constitute the arterial wall, obtained by spirally cutting the aorta of one of the larger animals. But though fully admitting the efficiency of these ligatures in his hands, I cannot but feel that it is unsatisfactory, if it can be avoided, to have a special material for this particular purpose, and it will be better, if possible, to have the catgut in a thoroughly reliable condition. Catgut, of which I have samples here, is to be had all over the world in abundance. It is beautifully strong and smooth; it is prepared of various sizes, admirably adapted for all the purposes of the surgeon, and is extremely cheap. Wholesale it is sold at 12s. per gross, that is to say, 1d. per hank. But, as it comes from the maker, it is entirely unfit for the purposes of the surgeon. However beautiful it is in the dry state, it becomes soft and pulpy soon after it has been placed in blood-serum. In one of these glasses is a piece of unprepared catgut which was placed in warm blood-serum this morning—the blood of a cow—and within half an hour it was in the condition in which it is at the present time—swollen, soft, and pulpy. A knot tied upon it would hold as little or scarcely better than a piece of intestine from which the catgut is derived in the dead-house—an utterly unsatisfactory material, soft and slippery, the knot not holding in the

least. It is essential, in order to fit catgut for the purposes of the surgeon, that it must be altered in its physical constitution, so as to be no longer liable to this softening effect by the serum of the blood. This is a remarkable circumstance, that the blood-serum softens catgut more than even water does. I confess I should have thought, *à priori*, that in the case of a colloidal substance like albumen, a solution of albumen would have been much less likely than water to permeate and soften an animal tissue like catgut; but it is otherwise, and therefore we cannot trust the trustworthiness of catgut by steeping it in warm water as I formerly used to do. In order to be sure that a given specimen of catgut will answer the purpose in so far as the knot is concerned, that it shall not slip, it is needful that we should steep the catgut in blood-serum, a somewhat troublesome process, as it involves sending to the slaughter-house for blood. The method which I published long ago answers the purpose very well for ligature of arteries in continuity, provided certain conditions in its preparation be complied with; such, at least, is my own experience. This indeed has not been very extensive, but it has been sufficient to deserve consideration. I have tied altogether nine considerable arteries in continuity with prepared catgut. Of these one was a case of ligature of the carotid in a young woman, aged twenty-two, with a pulsating tumour below the angle of the jaw, in the situation of the carotid aneurism, and with all the symptoms of that disease. The application of the ligature reduced to a certain degree the pulsation and the dimensions, but the further cure which we hoped for did not take place. She left the hospital with a pulsating tumour, and I heard only yesterday from the medical man under whose care she is in Scotland, that this tumour, for which I had tied the carotid artery in 1874 still exists as a pulsating tumour, if anything rather on the increase. But though, as regards the cure of the disease, the ligature was unsatisfactory, nothing could be more beautiful in its effect as respects the healing of the wound without suppuration.

A case of traumatic arterio-venous aneurism of the temporal artery may be mentioned in the category, partly because the greatly dilated condition which the naturally small artery had assumed brought it up towards the dimensions of a large trunk, and partly because the concurrent ligature of the largely dilated veins would, without antiseptic means, have been justly regarded as of considerable danger. The others were all cases of ligature of the femoral. Six were popliteal aneurisms, four of which presented nothing deserving of special remark. One was a diffuse aneurism, extending up to the junction of the lower and middle third of the thigh. One was an enormous diffuse aneurism reaching up nearly to Poupart's ligament. It was necessary for me to tie the femoral artery about the situation of the ordinary origin of the profunda, and even there my incision opened into the aneurismal clots. The last was a case of a large arterio-venous aneurism of the upper part of the femoral of idiopathic origin. This case was of such special interest that I hope on a future occasion to make it a subject of a paper before this Society. In all these cases except two the catgut ligature prepared by the old method was employed, and in all these nine cases the result was satisfactory, and recovery perfect, except as regards the poor young woman who has still the pulsating tumour. Why, it may naturally be asked, has my own experience been more satisfactory with the catgut ligature than that of many other surgeons? There are, I believe, two reasons for this. One is, that I have never ventured to tie an artery of considerable size in its continuity without having taking pains to ascertain that the catgut was of thoroughly reliable material; and the other reason is, that I have adopted strict antiseptic means of treatment not only during the earlier stages of the case, but to the last. So long as any sore exists unhealed, antiseptic treatment of the strictest kind ought, I believe, to be employed.

Even though the sore may seem to be superficial, there may still exist a sinus leading down to the site of the ligature, and if ordinary treatment as distinguished from antiseptic be employed down this sinus, the septic process may advance and invade the ligature, and lead at last to disaster from hemorrhage. I know that this has actually taken place.

But although the catgut prepared upon the old method answers very well if it be of proper quality, there is this great objection to it—that this method requires a long time in order to produce this quality. At least two months are needed to make the ligature at all trustworthy. It is better at the end of six months, and still better at the end of a year. I possess catgut prepared in this way twelve years old; I have brought here a sample of such catgut, which has been steeping in warm blood-serum since this morning, and it will be seen that it remains translucent, and is comparatively firm, instead of being opaque and soft like the unprepared catgut in the same serum.

Now, this length of time that the present method requires is a very serious objection. It makes the surgeon who has not prepared the catgut for himself, and kept it for a long time, at the mercy of the person who supplies it; and the person who supplies it, not being aware of the enormous importance of the time for which the catgut has been prepared, if he happens to have run out of that which has been long prepared, will sell what has been prepared for a short time, and is in consequence altogether unreliable. A case illustrating this point occurred last year in my practice at King's College Hospital. A patient was admitted who had met with a severe wound on the ulnar side of the forearm, the anterior aspect. The ulnar artery had been divided. This had been secured by my house-surgeon. He had also tied with catgut the corresponding ends of the various tendons that had been divided. But when I saw the patient the next day I found that he could not feel with his little finger and the adjacent side of the ring finger, and therefore it was evident that his ulnar nerve had been divided, and my house-surgeon had not thought of attending to the ulnar nerve. I therefore said, "We must open up the wound, search for the ends of the ulnar nerve, and tie them with catgut." I thereupon cut the stitches in the skin, and proceeded to explore the deeper parts of the wound, and I found that every one of the ligatures, which were numerous, by which my house-surgeon had tied the various ends of the tendons together, were lying absolutely loose; the knots had slipped within the twenty-four hours; and yet this catgut had been supplied by our ordinary instrument-maker as reliable catgut. He had supplied what had not been sufficiently long prepared. This, then, is a sufficiently serious objection to the present method of preparation; and one great object which I have had in view in a series of experiments on this subject, with a view of improving the preparation of the catgut ligature, has been to devise a means, if possible, of preparation within a short time. These experiments—it may seem almost ludicrous to say so—have occupied two years of my leisure time in the past, some time ago, and, after having been interrupted, have been continued in a merely desultory manner since; but at length I feel myself justified in bringing before you a new mode of preparation, by which the catgut can be prepared in a short time, and at the same time in a perfectly reliable condition.

But before I allude to these experiments, which I must endeavour to do in a short compass,—I should weary you if I were to bring a large proportion of my facts before you, though I may say, out of the hundreds of experiments I have performed on the subject, I have never performed one which has not added something to my knowledge on the subject,—before referring to these experiments, I wish to say a few words as to what catgut is. Catgut, as you are doubtless all aware, is prepared from the small intestine of the sheep. The small

intestine of the sheep is treated in what seems an exceedingly rude manner for so delicate a structure. It is scraped with some blunt instrument, such as the back of a knife, over a board, and by this means, as the people express it, the dirt is scraped out. That which these people call the dirt is the exquisite and complicated structure of the intestinal mucous membrane. The intestinal mucous membrane is scraped out by means of the back of the knife. But while the mucous membrane is scraped out from within, there is also scraped off from without, or from more external parts, the circular coat of the muscular fibres. The circular muscular fibres are disposed of, and the result comes to be that the intestine is converted into a comparatively slender material of two parts, the one consisting of the peritoneum and some longitudinal muscular fibres; when the mesentery is stripped off by the butcher, the peritoneal coat contracts into a narrow band, and this, with some longitudinal fibres, constitutes one of the two parts to which the intestine is reduced by this process of scraping. The other part is the essential part from which the catgut is prepared, and this is neither more nor less than the submucous cellular coat of the intestine. When I first visited a catgut manufactory I was astonished to find that after this scraping process the intestine could be blown up still as a continuous tube, as you will see here. This structure is a beautiful anatomical preparation, made, though in this rude fashion, by these preparers of the catgut. The submucous cellular tissue or submucous cellular coat of the intestine which is in the sheep has this extraordinary toughness, and is the material out of which catgut is prepared. For what the manufacturer terms the "ones"—the thicker form of ordinary catgut—all that is done is to twist the gut by means of a wheel, like a rope in a ropewalk, up to a considerable degree of tightness, and then allow it to dry. It is then exposed to the fumes of burning sulphur, and for some more special purposes it is somewhat bleached by the application of potash. But the essential thing is the twisting and drying. It can be prepared without the use of sulphur as well as without the use of potash. Some specimens which I have here are prepared by water only, without the use of any other ingredient. This exceedingly beautiful structure, as I think we must consider it, as fine as a horse-hair, is prepared without any ingredient whatever, nothing but an animal tissue twisted and dried. For the finer kinds the tube of the submucous coat is split up by means of razor-blades, more or less numerous according to the degree of splitting required, connected with a conical piece of wood which is pushed along the tube.

Such is the catgut. It is composed of the submucous cellular tissue. The first of the more recent experiments which I performed was one with a view of ascertaining, if possible, what part the water had in the material used for the preparation by our old method. If I steep unprepared catgut in a mixture of carbolic acid and oil, however long it be so steeped—it will be of course abundantly antiseptic—it is utterly unfit for the purpose of the surgeon, a knot upon it would still slip. But if, instead of using carbolic acid in the crystalline state, we use carbolic acid which has been liquefied by the addition of a little water, we get in course of time a properly prepared catgut. I wished to ascertain how much water was required. The carbolic acid would enable oil to dissolve a certain amount of water; would that amount of water be sufficient which carbolic acid enables oil to dissolve? Accordingly I prepared some jars, some containing the full amount of water we had used hitherto, some the smaller quantity, and some none at all. In due time I proceeded to examine the result by taking portions of gut and putting them into warm water and leaving them for a certain time in order to ascertain how the knots would hold. To my great surprise I found that which had been steeping in the carbolic acid and oil without any water was just as good as that which was in the carbolic acid and oil with the water. It was contrary to

distinct previous experience. Reflecting on the matter made me see that the only possible explanation could be that the catgut was, so to speak, prepared before I put it into the liquid. Now, it so happened that the catgut I had used was several years old: it turned out that the mere age of the catgut prepares it—that in proportion to its age it is rendered less liable to be softened by water or by blood-serum, and a knot tied upon it will hold better. And thus I had for the first time, I believe, scientific evidence of the truth of what is popularly spoken of as the "seasoning" of various articles made of animal products. I asked a person who sold violin-strings if there was any result from keeping the strings a long time. He said, "No," the only result he knew was that they would probably get rotten. But it so happened just about that time there came an old fiddler to amuse the patients at the Royal Infirmary of Edinburgh at Christmas-time. They happened to have wet weather, and he said that his fiddle would not work properly because the fiddle-strings were not properly seasoned. So that he was aware that fiddle-strings, which of course are catgut, are liable to seasoning, and require it. This is a very important fact—at least, it was extremely important to me, because it served to explain the success that I had had in my earlier experience with the catgut, before I knew at all the proper modes of preparing it. I look back almost with horror at some of my early procedures with catgut. I have operated, for example, on an irreducible ventral hernia, opened the sac, divided the adhesions, returned the protruding intestines, stitched up the mouth of the sac with the catgut, and then applied stitches at considerable intervals in the skin. All went perfectly well, but the mode of preparation that I then used, if I had worked with catgut recently made, must have ended in utter disaster; the knots must have slipped in a few hours, and the intestines must have been protruded through the wound. I need hardly say that this mode of preparation, interesting though it is, would not be satisfactory; it would only have, in a more aggravated form, the inconvenience of the extremely long period required which our old method has; and, besides that, it by no means provides all the conditions that are required for a perfectly satisfactory state of the catgut for surgical purposes. These conditions I may mention. In the first place, I have spoken of a short period of preparation. This is very desirable. Then it is essential that the catgut should have the proper strength, so as to bear any reasonable strain that the human hands can put upon it in the thicker forms, as when used, for instance, in such cases as the ligature of the thyroid vessels, in the removal of a thyroid tumour, or in ovariotomy. But it is not sufficient that it should be strong to start with—it is easy to get catgut strong in the dry state—it is necessary that it should be strong after steeping in blood-serum for a while. Suppose, for example, in the case of tumour of the thyroid I had passed the various ligatures. I passed in that case six, and in a former case, where the tumour was larger, I thought it prudent to pass as many as eight so as to subdivide the mass that had to be tied; but it is not convenient to tie each of these ligatures as soon as it is passed. The process of passing takes a considerable time, and it would be a very sad thing if the residence of the catgut among the tissues soaked with serum for a few minutes, or even a quarter of an hour, should render the catgut so soft that it should give way when we put the strain of the hands upon it. That, then, is another point that is essential if it is to be useful for the purpose for which it is devised. Then, again, it is necessary that a knot tied upon it should hold it with absolute security—not merely in the first instance, but after soaking for an unlimited time in blood-serum. It is further necessary that it should not be too rigid; that it should not be over-prepared, for, as we shall see immediately, it may be over-prepared, so that it may remain almost like a piece of wire among the tissues, in which case it may come away in consequence of the

irritation which it produces as a mechanical object, as a hard mechanical substance. It is necessary that it should be somewhat soft, so as to be mechanically unirritating; and yet while it must be soft it must not be too rapidly disposed of by absorption. If it is to do duty for the ligature of an artery in its continuity in the immediate vicinity of some large branch, it must remain for a considerable time of good firmness, unabsorbed, and when it is at length absorbed it is desirable that it should be absorbed in such a manner that while it is reduced in thickness it should still, as long as any of it remains, retain its firmness.

Now, these are a series of conditions which, I assure you, it is not easy to comply with. I have in various experiments complied with some of them easily enough, but failed in others. Sometimes I have complied with all but one, and failed in one. I have used various materials in experiments, as you will naturally suppose. One material that suggested itself was tannic acid, so as to convert the catgut into leather. I succeeded well enough in some respects with tannic acid in different ways modified, but in this respect I did not succeed. I have not obtained by means of tannic acid a kind of catgut that is not too speedily absorbed. I tried at last a piece of kid leather cut into a suitable shape, and I found that this, after being rendered antiseptic, and applied as a stitch, became too rapidly absorbed. Chromic acid was another substance which I very naturally used, knowing as I did how it was employed for hardening tissues. Chromic acid in itself does not work very well, but I found that the addition of some other substance to it aided its action very greatly. By the addition, for instance, of a little glycerine, thus producing a reducing action on the chromic acid, we get a different sort of material which acts much more energetically on the catgut. I was highly delighted with the results of the action of a mixture of chromic acid and glycerine. Just about this time it so happened that Mr. Alfred Pemberton, of Birmingham, applied to me for a piece of catgut for the purpose of ligaturing an external iliac artery in a remarkable case of three aneurisms in one limb—two in the femoral, and one in the popliteal. I thought I could not do better than send him my recently prepared chromic catgut. I did so. He wrote to me soon afterwards, saying that nothing could be more satisfactory than the result. He had operated antiseptically; the wound had united by first intention, and a month afterwards, so far as the case could go well, all had gone well. There was, indeed, gangrene of the lower part of the leg, which Mr. Pemberton predicted, in consequence of the existence of the obstructions of the ligatures of three aneurisms in the course of the arterial channel; but the case, by proper management, was doing well, and ultimately the patient recovered, though with an amputated limb. But four weeks later Mr. Pemberton wrote to me again, telling me that soon after his last report the patient had begun to show signs of suppuration about the seat of the wound. After awhile the abscess opened in the cicatrix, and the ligature which he had put on was discharged. It is now on one of the cards before you —an over-prepared ligature which had come away, rigid and wire-like, making its way out as a piece of glass might have done, by mechanical irritation. This opened my eyes for the first time to the possibility of having catgut ligatures over-prepared. It is by means of chromic acid, however, that I have arrived at the ultimate result which I have to bring before you. I may mention that the over-preparation by means of chromic acid is, I believe, to be found illustrated in a large German school at the present time. I have been told by an American physician who has lately been in London that at that school catgut ligatures invariably come away from all wounds. They count the ligatures as they put them on, and invariably see them all before the case is done with. The ligatures have been over-prepared.

Before speaking of the present method, I wish to say a few words with regard

to the old method. To what is it that it owes its virtue? Here we have some catgut which has been in our old preparing liquid, viz., one part of carbolic acid which has been liquefied by means of water, to five parts of olive oil. Here we have some catgut which has been the same length of time, since April last, in a solution of carbolic acid and water. Water will only take up one-twentieth part of its weight of carbolic acid, but the effect produced upon the catgut is very much greater. In the one case, as you can see, the catgut is almost black, a sort of purple black, while the other is completely pale, very little altered from its original colour. This circumstance shows two things. In the first place the effect of the watery solution of carbolic acid upon catgut explains the efficacy of the water in our old method. It is the watery solution of carbolic acid in the liquid of the old method that is the effective agent. But, while that is the case when this watery solution is mixed with oil, the fact that it is so mixed limits and checks its operation, whereas if we have it in the watery solution only, there seems to be no limit to the degree of continuous preparation of the gut, so that it becomes more and more dark in colour, and more and more difficult to absorb by the tissues. It is otherwise when the watery solution is blended with the oil. Though the process does go on for many months, there arrives a time when it comes to a standstill. You need not fear that the catgut prepared by the old plan is over-prepared at the end of two years. I have a specimen here which at the end of twelve years is as limp after steeping in blood-serum as it would have been at the end of a single year. Therefore we possess in the carbolic oil a means of checking any mode of preparation that we may adopt, keeping it from that time forward not materially further prepared; while at the same time this large proportion of carbolic acid to oil insures the catgut being perfectly aseptic.

The method which I have found, after various trials, to be that which may be recommended is the following: I take one part of chromic acid, 4000 parts of distilled water, and 200 parts of pure carbolic acid or absolute phenol. In other words, I use a one-to-twenty carbolic acid solution, only that the carbolic acid is dissolved not in water, but in an exceedingly dilute solution of chromic acid. This small quantity of chromic acid has a very great effect upon the gut. Into a solution of that composition I introduce catgut in weight about equal to the weight of the carbolic acid. If you have too large a proportion of catgut, it will not be sufficiently prepared; if you have too small a quantity it may run the risk of being over-prepared. This liquid seems really to answer the purpose, and to comply with all our conditions. At the end of forty-eight hours catgut steeped in such a solution is sufficiently prepared. It is then taken out of the solution and dried, and, after drying, placed in one-to-five carbolic oil; it is then fit for use. I have here a sample of the prepared catgut by the new method. Although it has been steeped in warm blood-serum since this morning at eleven o'clock, it is still firm and translucent, and a knot upon it holds with the most perfect security.

The strength of the catgut depends upon different circumstances. In the first place, sheep differ as to the strength of their intestines, and the catgut-maker, if he be a good one, will insist upon having sheep of the proper kind. In the next place, the intestine must not be allowed to putrefy—it must be taken fresh. For these things you must of course rely upon the maker of the catgut. In the next place, whatever method you adopt, the liquid will probably cause a certain amount of swelling of the catgut, and this will tend to produce a little uncoiling of the twisted gut. It is of very great importance that this should not occur, because, if you have uncoiling, you may have uncoiling of different degrees in different parts, and this may lead to weakness at some part which you cannot foresee, and the gut may give way when you subject it to a strain. The catgut, then, should be prepared on the stretch, both when it is put to soak and when it is put to dry.

I need not enter into the mode in which this can be done by the manufacturer. I may only say this, that the private surgeon who wishes to prepare it himself may do it in different ways. For instance, he may take two large test-tubes, one a little larger than the other, and he may wind the catgut on the smaller tube, fixing one end by sealing-wax, winding round, and then bringing it up again, and fixing the other end with sealing-wax at a higher level than the liquid will come to, putting sufficient liquid into the larger test-tube, and putting in the smaller test-tube with the catgut wound round it, with a little shot to keep it down in the liquid. After forty-eight hours he takes out the smaller test-tube, and leaves it till the catgut is completely dry. I merely mention this as an illustration, and also as furnishing a hint to some surgeons in private practice who may desire to prepare the catgut themselves. Or a couple of gallipots, one larger than the other, will do just as well.

So much for strength in the dry state. As to strength in the condition after steeping in blood-serum, I confess it is only this very day that I have obtained evidence that catgut prepared by this method is really all that we can desire in that respect. The catgut of the hank from which this specimen was taken in the dry state measured 2¾ hundredths of an inch in diameter, and broke at 13 lbs. A piece 2¾ hundredths in diameter broke at a strain of 13 lbs. 6 oz. I found by experiment that 10 lbs. is the utmost strain that my arms are able to put upon a cord. 13 lbs. 6 oz., then, is amply sufficient, while at the same time the catgut is not at all too large for going into the eye of an aneurism-needle. Having obtained, the other day, some fresh blood of a cow from the slaughter-house, I took some of the serum to-day, and put two pieces of this same hank of catgut, prepared after this new method, in the serum, and I put this in my warm box in a stoppered bottle. The temperature of the box was 98° Fahr. After more than half an hour I tested the breaking strain (I must not stop to explain how that is done), and I found that the breaking strain of the same catgut, which in the dry state has broken at 13 lbs. 6 oz., was 11 lbs. 4 oz.—that is, though suppled by the serum, it had only lost in strength 2 lbs. out of 13 lbs. I think that is really all that can be desired.

As to the behaviour of the catgut among the tissues, I wish to say a few words on this point before I conclude. It has been said of late by various persons that the catgut is dissolved by the serum. I must confess that this is entirely contrary to my own experience. I have already said that in order to test the quality of catgut you must have it steeped in blood-serum. I have tested catgut prepared in various ways in this manner. The serum has sometimes been putrid, sometimes it had no smell at all, and sometimes it had a little odour. This serum has been kept about the temperature of the body, but I have never seen the slightest indication of any chemical solution of the catgut. Then, again, as to the behaviour of the catgut in the body, suppose we use it as a stitch, if the catgut were disposed of as a matter of chemical solution we should expect that when it is employed as a stitch and a piece of our protective is put over it, which is always kept moist with serum perpetually oozing from the wound, the outer parts of the stitch, the parts outside the skin, as well as the parts among the tissues, would show signs of diminution. It is never so. The diminution is always absolutely limited to the parts within the tissues. Then it is still more striking, perhaps, as was suggested to me by Mr. Cheyne, to consider the case of the catgut drain. There its very function is to drain out the serum, and it is perpetually washed with it. You might suppose that the stitch would get a little dry. Here there can be no mistake; the serum from the wound is perpetually flowing; yet, as in the other case, we find the diminution of the catgut is absolutely limited to the part within the tissues. This seems to me sufficient evidence that it is not a ques-

tion of the mere chemical solution of the catgut, but a question of the disposal of the catgut in some way or other by the living textures. Then, again, if we examine catgut in the process of diminution we find that it may be effected in one of two ways. If the catgut has not been properly prepared, the substance of the catgut becomes converted in the course of a very few days into a soft, pulpaceous mass, which, when we examine it by a microscope, we see consists of remains of the old cellular tissue of the submucous coat, and the interstices among these fibres filled with cells of new formation. The catgut tissue is infiltrated with cells of new formation, and it is obvious it is this infiltration which is the cause of the softening. But, on the other hand, if we find that the catgut is properly prepared, instead of being infiltrated by the cells of new formation it is only superficially eroded. I have on one of these cards a pretty example of catgut that has been served in that way by the tissues. You will see that there remains a very slender residue of the catgut, all the rest having gone; but that slender residue has continued firm and translucent, still retaining its firmness, showing not even a superficial infiltration—in short, having exactly the characters that we desire for catgut required for the ligature of an artery in its continuity, that till the last, even though reduced in dimensions, it shall retain its firmness and its tenacity. We know that antiseptic treatment has shown that a piece of dead bone may be absorbed provided it be not putrid: the granulations that overlap it superficially may, so to speak, erode it. It is not necessary for us to consider how that may be done, but certainly in some way or other the granulations do what mere steeping in that serum, whether putrid or non-putrid, never would do. Never would the bone be dissolved by the serum. Just as a non-putrid sequestrum is served by the tissues, so is a well-prepared specimen of catgut; it is superficially eroded. I have here a stitch that I removed to-day from a wound made for stretching the anterior crural nerve, which was stretched, as well as the sciatic, in an aggravated case of sciatica; and you may see that as yet it shows no signs of erosion. We know by experience that if it were left three or four more days we should find it largely eroded, as these specimens show; but until nearly a fortnight has elapsed erosion does not begin. It proceeds gradually, and the thicker the catgut the slower does it proceed. We may fairly consider that a fortnight or three weeks is long enough for the persistence of a ligature upon an artery in its continuity.

I have brought with me the carotid artery of the calf in which I first established the fact of the substitution of new living tissue for the dead old tissue of the catgut. If any gentleman will examine the specimen he will see the ligatures of new formation incorporated with the external cellular coat of the artery. I am sorry that I am not able so to express myself in the English language as to make my meaning understood. I have been strangely misrepresented as having conveyed the idea that the catgut, when it becomes organized, comes to life again. Gentlemen, such an absurd notion certainly never entered into my head, any more than when I have spoken of the organization of a blood-clot, I have meant by that expression to convey the idea that the blood-clot becomes organized by its own inherent virtue. I found the term organization ready to my hand; it was no term of my own invention. It was used with reference to lymph. Now, pathologists, in speaking of lymph as becoming organized, did not, I suspect, mean by that expression to imply that it was the lymph substance that had the power of self-organization as distinguished from any influence that surrounding tissues might exert upon it. So, in the same way, when we speak of the vascularization of lymph, that was the term used when it was universally believed by pathologists that the bloodvessels were formed only by loops from pre-existing bloodvessels. Nowadays a different view may be taken, but the term "vascularization of lymph" was used without any idea that the lymph itself created

the bloodvessels. And so, when I spoke of the organization of the blood-clot or of catgut, I certainly never meant to convey the idea that either the one or the other did the work itself. With regard to the catgut, I think if gentlemen would refer to my original paper in the *Lancet* they would see that I stated very explicitly that new tissue forms at the expense of the old, that the old tissue is absorbed by the new, and that as the old is absorbed, new is put down in its place.—*Med. Times and Gaz.*, Feb. 5, 1881.

Medicine.

Diphtheritic Albuminuria.

The albuminuria which occurs so constantly in diphtheria was long believed to be a direct effect of the altered blood-state, without any renal lesion. Lancereaux and Brault, however, have described certain organic changes in the kidney. They found the epithelial cells swollen, badly defined, infiltrated with granules of protein, and the lumen of the tubules obliterated in many points by colloid or granular masses. These lesions are analogous to those described by M. Cornil in acute poisoning by cantharadin.

The nature and mode of production of this diphtheritic nephritis is the subject of a recent communication by M. E. GAUCHER to the Société de Biologie. It may be *à priori* expected that the lesion would be due to the same mechanism as that which produces the similar changes which have been found in some other infectious diseases. In the nephritis which sometimes occurs in typhoid fever, for instance, there is a similar granular infiltration of the epithelial cells and a similar obstruction of the lumen of the tubules by diffused material or globular masses. These alterations have lately been ascribed by Bouchard to the infiltration of the kidney by bacteria. In a case of malignant diphtheria in which the urine contained a considerable amount of albumen, M. Gaucher, adopting all precautions to prevent the access of external germs, was able to demonstrate without difficulty the presence of bacteria in both the blood and the kidneys. The urine was collected in a glass, washed with alcohol and heated, and, examined immediately, was found to contain a large quantity of spherical or punctiform mobile bacteria (monads or micrococci). There were no rods or chains. In the blood the same organisms were found, less numerous, but perfectly distinct. The patient died seven days after the onset of the disease. The kidneys, examined in the fresh state, were found crammed with bacteria similar to those which had been found in the urine and the blood during life. The epithelial cells of the urinary tubules were filled with highly refracting granules, strikingly similar to the micrococci found in the urine. In sections which had been hardened in osmic acid the same granules were found. From these facts Gaucher concludes that diphtheritic nephritis is of parasitic origin, and that the albuminuria is the result of the passage of the bacteria of the blood through the kidneys. The albuminuria is thus to be regarded as an effort at the elimination of the poison.—*Lancet*, March 5, 1881.

Syphilis and Tabes Dorsalis.

WESTPHAL (*Archiv f. Psych.* xi. p. 230) concludes that an etiological relation between syphilis and tabes is unsupported either by clinical or pathologico-anatomical facts. In 75 cases, whose histories were comparatively well ascertained, he found chancres in 14, chancres and secondary symptoms in 11. Nine-

teen out of 20 cases occurring in women had no history of chancre, and the twentieth case was a doubtful one. In one case only were secondary symptoms present whilst the patient was under observation. Of 16 cases that came to autopsy one only showed evidences of syphilis, and in another the appearances were doubtful. Further, Westphal has never seen a case of gray degeneration of the posterior columns cured by anti-syphilitic remedies. Remak (see *Centralblatt f. d. med. Wissensch.* 1880, No. 43) obtained a history of syphilis in 25 per cent. of his cases of tabes, nevertheless he does not admit a direct causal connection between the two. Bernhardt admits that syphilis may produce tabes, but it is not nearly so potent a cause as is often supposed.

Westphal reports a case in which, besides other lesions of a syphilitic nature, there was disease of the posterior columns in the upper cervical region. The medulla of the nerves had disappeared, but the axis-cylinders were intact, and in some places seemed larger than normal. The vessels were dilated and their walls thickened. There was no increase of connective tissue or proliferation of nuclei, no corpora amylacea, no cells with fatty granules. The changes were evidently due to a peculiar parenchymatous affection. A gumma was found in the posterior part of the corpus callosum. Westphal compares this case with one recorded by Schultze, in which there was a tumour of the anterior part of the corpus callosum and degeneration of Burdach's columns down to the lower dorsal region. In Burdach's columns the nerves had lost their axis-cylinders, but for the most part retained their medulla. The neuroglia was normal.—*Brain*, Jan. 1881.

On the Early Stage of Locomotor Ataxy.

An early recognition of ataxic tabes is of the highest importance, as it is only at the earliest stage of the disease that we can hope to do much good by our remedial measures. The ocular symptoms are frequently the earliest; and among them the author draws attention to a sudden and transitory paralysis of accommodation of one eye. This may be the only trouble present, but is often accompanied with mydriasis paralytica. These symptoms may precede the actual invasion of the disease by some years. Then dissociated paralyses of the third, of the fourth, and sixth nerves may intervene, as well as spinal myosis, which is characterized by absence of reaction to light, but not to the accommodative impulse. Or, again, mere sluggishness or absence of reaction to light may be present. Charcot has well described the progressive optic atrophy; the papilla presents the appearance of a flat depression according to MÜLLER, and the vessels gradually become smaller. The field of vision diminishes concentrically in the two eyes unequally, the region of dimness has the shape of sectors having (not the fovea, but) the papilla as centres; and this diminution is much more readily appreciated on indirect vision. Achromatopsia may occur, first to green, then to red. In disseminated sclerosis the sense of colour is preserved. The author recommends Doucet's perimeter as the most convenient to test these defects in practice.

The lancinating pains present various peculiarities which need not be dwelt upon here; the various other defects or alterations of sensibility are also well known. Berger has shown that there may be deficient algesia to powerful stimuli, whilst weaker ones are responded to. Retardation of transmission of sensations is not very common. The sense of pressure is often deficient at an early period.

The well-known "tendon reflex" may coexist with ataxia (in 2 cases among 82: Berger). Certain facts lead the author to suspect a period of heightened reflex preceding its abolition.

[I have now under observation a somewhat doubtful case, in which there are shooting-pains in the left leg with very diminished tendon reflex, and markedly increased reflex in the right. The right hand is the seat of progressive muscular atrophy.]

Erlenmeyer has prominently brought forward the early gastric symptoms of tabes; they either take the form of nervous dyspepsia or actual catarrh. These symptoms have the characteristic suddenness of many tabetic symptoms.

The genito-urinary organs present numerous forms of disturbance. We may note here urethral and rectal neuralgias, causing spasmodic contraction of the bladder, and tenesmus.

The well-known crises gastriques may constitute for a long time the chief feature of the disease, and may require care in their diagnosis from other stomach ailments. The pneumogastric may be affected differently, and give rise to tremendous fits of coughing. The "crises néphritiques" need only be mentioned here.

Arthropathies and osseous fragility may appear early. The pulse is usually frequent. The sweat, increased at first, becomes deficient later on, and is not readily induced by pilocarpine in the diseased regions. The ataxic symptoms are usually pathognomonic of the second period. The author has noticed two cases of early peroneal paralysis.

The treatment of tabes at this initial stage consists, first, in a strict hygienic mode of life; second, in the administration of ergot and nitrate of silver, a mild course of hydrotherapy (the water to range between 20°–25° centigrade) and electricity. The latter is to be applied centrally by means of large electrodes (2×6 inches), using a current strength of 8–11 milliwebers; and may be also usefully applied symptomatically for relieving the ocular troubles, the gastric pains, etc. Against the latter and the shooting-pains Chapman's bags may also be used with success.

The author next discusses the anti-syphilitic plan of treatment, and condemns it—first, because it is useless; second, because he does not consider the syphilitic nature of the disease as demonstrated. Several instructive cases bring Dr. Müller's valuable paper to a close.—*Brain*, Jan. 1881, from *Mittheilungen des Vereines der Aertzte in Steiermark*, 1879.

—

A Case of Chronic Vomiting in which no Food was taken, except Koumiss, for Sixteen Months.

At a late meeting of the Clinical Society of London (*Med. Times and Gazette*, Feb. 26, 1881), Dr. H. SUTHERLAND related this case. The patient, a girl, aged twenty-four on admission, had been for five years under his care at St. George's, Hanover-Square, Dispensary. One year and seven months ago the vomiting commenced, the attack coming on at first only once a fortnight, but lately it had occurred always once, and sometimes five or six times a day. As far as could be ascertained, there was no organic disease of the stomach, no tenderness on pressure, or cachexia, nor any other constitutional symptom. Every known remedy was tried to allay the vomiting—bismuth, opium, hydrocyanic acid, creasote, carbolic acid, hyposulphites, etc.—without any satisfactory result. All attempts to cure the case by dieting had failed, and the patient could keep nothing on the stomach as food except koumiss, which she had taken for sixteen months. She is, however, able to retain a quinine-and-orange mixture, and also sherry in small quantities, for brandy makes her sick immediately. The uterus was not displaced. The object in bringing the case before the Society

was to ask if members could suggest any remedies or mode of treatment in this distressing case.

Dr. JAGIELSKI had found that koumiss could often be retained and do good when nothing else would. The case just recorded was probably unique, inasmuch as koumiss was required for eighteen months, and that the patient had decidedly improved under its use. Often, koumiss could be borne when milk could not. This might be because the casein had been broken up by the carbonic acid in the process of production.

Dr. BROADBENT inquired whether the patient had been engaged in any kind of work or been entirely idle during the period referred to. The case was in all probability one of hysteria, as indicated by the nervous condition, the irregular menstruation, and the regular morning and evening vomiting. It belonged to the fasting-girl class.

Dr. B. O'CONNOR mentioned a case where he had used various forms of milk and Valentine's beef extract with success. He found that, in some cases, the upper portion of the milk after standing suited best.

Dr. WILBERFORCE SMITH said that in such cases the stomach could not digest nitrogenous substances, and that therefore he would recommend cream and fat boiled with water-biscuits as an alternative diet.

Dr. DOWSE asked how much koumiss was given in the twenty-four hours. The case was evidently a nervous one, and he would suggest that solid instead of liquid food be tried.

Dr. SUTHERLAND said the patient lived at home and did no work. The case was not, he thought, hysterical, but the patient was bad-tempered and inclined to suicide.

—

Post-mortem Emphysema from Gastric Ulcer.

Among the causes of subcutaneous emphysema ulcer of the stomach is one of the rarest. An instance has, however, lately been reported by POENSGEN in the *Deutsches Archiv für Klin. Med.* The patient was a man aged thirty-seven years, who had for three years presented the symptoms of gastric ulcer. He had been treated by washing out the stomach by a douche, and was relieved. A fresh attack of vomiting occurred, and he died suddenly on his way to the hospital. A short time after his death, the abdomen, chest, neck, head, face, arms, and the left leg were gradually invaded by enormous subcutaneous emphysema, which was also found after death in the connective tissue of the mediastinum and beneath the peritoneum. In the smaller curvature the wall of the stomach was perforated by an ulcer, and on the inner surface of the abdominal wall was another ulcer, which had apparently corresponded to the perforation in the stomach, and through it the gas from within that organ had seemingly escaped into the cellular tissue.—*Lancet*, Jan. 22, 1881.

—

Nature of the Green Vomit.

The chemical and microscopical nature of green vomit has been made the subject of recent investigations by Dr. F. BETZ (*Mémorabilien*, Oct. 6, 1880). It was supposed that the green vomit (*vomitus æruginosus*) was the result of a greenish discoloration of brown biliary pigment, caused by the acid action of the gastric juice. The supposition received corroboration from the bitter taste of the vomited matter, associated with its acid reaction. Dr. Betz concludes, however, that the green colour is not invariably due to the presence of bile. The colour often varies from a yellowish-green or grayish-green, to a grass-green or dark-green, in accordance with the greater or less amount of the green "substance"

and other admixtures. If green vomit be allowed to stand in a vessel, the greater part of the greenish substance will sink, whereas a small portion, containing slime and fatty matters, will float on top. Shaking with water shows that the green substance is heavier than water and insoluble in it, a proof that bile is not the cause of the colour. Agitation with chloroform or ether likewise demonstrates this, for neither fluid takes up the green substance. It may, however, be isolated by shaking with ether in a test-tube. This manipulation results in the appearance of three strata, an upper one consisting of ether, a middle one composed of the green substance, and a lower one containing the gastric mucus. Strong sulphuric acid produces a red colour, strong nitric acid leads to a yellowish discoloration of the green substance. Acetic acid develops and fixes the green colour very completely. Tincture of iodine produces a yellowish-brown, and not a blue tint. Alcohol dissolves the green substance. In some respects, it resembles the chlorophyll of plants. The alcohol dissolves it, and even retains the green colour when boiled. The green vomit may be kept for months and during the hot season, without spontaneous putrid fermentation taking place—a fact which militates against the possibility of its biliary or even animal nature. Dr. Betz also states that sometimes the green vomit has a neutral or alkaline reaction. Microscopical examination shows the green substance to consist of an amorphous, finely granular greenish mass. Discoid heaps, or rounded colonies, are commonly observed. But the green substance may also form a lining over epithelial cells, salivary corpuscles, etc. From these facts Dr. Betz infers the vegetable nature of this substance, and he adds that it is probably derived from punctiform algæ, which he calls *chlorococcus*. He denies any relation of this low fungus to other microphytes, such as the torula cerevisiæ, sarcina ventriculi, or oïdium. Finally, the author remarks that, apart from all other considerations, the frequent occurrence of copious green vomits would go to show that bile could not find its way into the stomach in such erroneous quantity. The bitter taste of the green vomit receives its explanation in part from the frequent admixture of some bile, but is also in part due to the presence of a bitter principle in the chlorococcus.—*London Med. Record*, Feb. 15, 1881.

—

Treatment of Infantile Diarrhœa by Charcoal in the Milk.

For children belonging to families in easy circumstances, M. J. GUÉRIN mixes a certain quantity of Belloc's powder of charcoal with each milk meal—half a teaspoonful only at each meal. For the children of the working classes, Belloc's powder, which is a little dear, is replaced by very finely powdered, farina-like, ground bakers' charcoal. This powder mixes readily with milk, and children drink the mixture as though the milk were pure. In a very short time, sometimes on the first day, the stools change in consistence and odour, and instead of being green, become blackish-yellow. At the same time that this addition is made, M. J. Guérin dilutes the milk with one-third or one-half of sweetened water, and the children take it without repugnance or vomiting. M. Guérin has frequently seen children, exhausted by seven or eight days' uncontrollable diarrhœa, regain in two or three days the expression of health.—*Lond. Med. Record*, Feb. 15, 1881, from *L' Union Méd.*

—

Causes of Contracted Kidney, and on the Diagnosis of Different Forms of Nephritis.

ZIEGLER (*Deut. Arch. für Klin. Med.*, Band xxv., sec. 586) says the chief factor in the causation of granular kidney is not the degeneration of the parenchyma, but the non-occurrence of its regeneration which can restore it to its

integrity. Simple fatty degeneration, which occurs in various diseases, in anæmia, and may be caused experimentally, has not succeeded in affording any explanation of granular atrophy. He starts with the investigation of senile atrophy of the kidney, in which, obviously in consequence of generally diminished nutrition, there occur enfeeblement of the circulation, wasting of the glomeruli, first at the periphery, then disappearance of the tubules connected with them, and finally more or less extensive small-celled infiltration. The arterio-sclerotic form of granular atrophy stands next to this. Here, the most important changes are wasting of the glomeruli, collapse and atrophy of the tubules, and finally, hyperplasia of connective tissue. Fatty degeneration occurs secondarily, but the cells become smaller, like those of the looped tubes; most contain cylinders. The vessels are widened, and this seems to be the cause of the increase of urine. The embolic form is similar to the latter. By obstruction to the greater circulation, and increase of the heart's action, the same changes take place in the kidney, which apparently originate in wasting of the glomeruli, perhaps in consequence of exudation into the capsules. Great interference with the nutrition of the kidney of different sorts may lead to extensive degeneration of the parenchyma; but regeneration takes place if the glomeruli have not been involved, or if the destruction be not too great or continued. When the latter occurs, atrophy results; as occasionally happens, for instance, in acute jaundice. It may also follow parenchymatous degeneration, as seen in the small patches of atrophy on the surface of the large white kidney; but generally atrophy occurs only rarely. The glandular degeneration, in all those forms which he groups together as interstitial indurative nephritis, is of secondary importance. The atrophy of the tubules is the result of their abolished function, of the destruction of the glomeruli, which latter depends upon fibrous hyperplasia of the capsules, or on a concomitant disease of the arterial system. Besides the form of atrophy from compression, he gives three groups of atrophy of the kidney. The first, of which the type is the arterio-sclerotic form, is dependent on simple interference with the circulation, and must be distinguished from the inflammatory forms. In the second, he classes all the degenerative processes which are followed by destruction of the epithelium (embolism, temporary ligature, chemical irritants), excluding regeneration. In the third group (interstitial nephritis), there is a combination of epithelial degeneration with other processes—cellular infiltration, proliferation of the epithelium of the capsules and glomeruli, wasting of the vascular tufts. Both the latter groups—which differ only quantitatively, not qualitatively, as in both there are epithelial degeneration and hyperplasia of connective tissue—are, nevertheless, to be kept distinct, as there is no "identical pathological principle," as Weigert thinks.—*London Med. Record*, Feb. 15, 1881.

—

Post-scarlatinal Nephritis.

The greater part of the contribution of Dr. HAJEK (*Archiv für Kinder*, vol. 1. pl. 10) agrees with the majority of articles to be found in German periodicals, in consisting almost entirely of an enumeration of the names of every one who has had anything to say on the subject in question, coupled with a partial criticism of their views, and concluding by leaving the question still in doubt, or only augmented by some trifling additional information. As articles of reference to what has been said, such papers are invaluable. Whether all that has been said is worth being referred to, is perhaps doubtful. With the uncertainty that exists as to the cause of the complex symptoms included under uræmia, this title is rather to be regarded as provisional; and the further question of the exact connection of nephritis with the acute exanthemata, especially scarlet fever, is still

uncertain. Uræmia is a constant accompaniment of diffuse inflammation of the kidneys; and researches on uræmic eclampsia have disclosed affections of the brain and cord, such as œdema, and even hemorrhage into the meninges and nerve-substance, which, according to Traube, by producing a capillary anæmia leads to convulsion, a theory at variance with what is usually held. Frerichs attributes the symptoms of so called uræmia to carbonate of ammonia, derived from urinary salts, whilst Voit regards the retention of all or some of the products of decomposition within the body as the cause, and compares the result to the extinguishing of a fire by accumulation of ashes. Caffer (1878), by injections of carbonate of ammonia into the blood, found that the corpuscles by the retention of this salt are materially changed in their structure and power of absorption of oxygen, and their number considerably diminished. Jaksch and Treitz suggest the decomposition of materials in the intestine as a supplementary source of ammonia. Mantegazza has seen muscular convulsions from injection of urinary matter as well as from the immersion of portions of muscle in urinary sediment. Perles and others speak of the quantity of kreatin and kreatinin in the blood in Bright's disease. In short, the connection between retention of urine in nephritis, and the appearances of uræmia or ammonæmia is yet so imperfectly defined, that Thomas, in Gabault's *Handbook of Children's Diseases*, says that uræmia arises upon some disturbance of the urinary secretion, and is probably occasioned by it. To the question, what is the pathological connection between nephritis and scarlet fever? the answer is, the long-continued, more or less complete, suppression of the perspiration. The constant results of complete or partial covering of the skin with oil, varnish, etc., are albuminuria, and diminished quantity of urine, fall of temperature, dyspnœa, convulsions, coma, and death. Corresponding *post mortem* to these symptoms are diffuse nephritis, pneumonia, myocarditis, and hepatitis. Some observers consider that death is due to increased radiation of heat from the distended superficial capillaries; others attribute it to uræmia, and the crystals of triple phosphates which are found in the bodies of animals so treated are products of urinary decomposition. Lang clearly explains the uræmia as being caused by disease of the looped renal tubules; since excretion of water by the skin is stopped, and the lungs cannot compensate, the tubules are blocked up, and retention of urine brings about the uræmia. Lassar supposes that the sudden determination to the internal organs of blood very much cooled at the surface of the lung, is itself a cause of inflammation. An identical train of symptoms follows extension of superficial scalds. The identity in symptoms and *post mortem* appearances between primary or scarlatinal nephritis, and those brought about by artificial suppression of cutaneous secretion, however produced, justifies the conclusion that in scarlet fever the same causes, viz., the suppression of perspiration, induces the same effects, viz., nephritis and uræmia. Barthez and Rilliet put forward the idea, in which they were supported by Baginsky, that the albuminuria depended upon the non-conversion into epithelium, for which it was destined, of certain albuminous matter in the blood, which was, therefore, excreted by the urine. Bohn opposed this view, and showed how the function of the skin is impeded by the œdema of the cutis, and the dead and stiffened epidermis. From this point of view the scarlatinal nephritis would seem not to be a local expression of the primary disease, and still less due to taking cold (that scape-goat of etiology, as Bartels says) during the desquamation stage, but to be a direct consequence of the fever from the conditions of the skin.—*London Med. Record*, Feb. 15, 1881.

Surgery.

Lister's Antiseptic Treatment in Surgical Wounds.

Bokckel (*Gaz. Méd. de Strasbourg*, Dec. 1, 1880) gives a table of statistics of major amputations performed by himself, some with and some without antiseptic precautions. Fifteen amputations of the thigh were performed antiseptically with four deaths, and seven were treated otherwise with three deaths; eighteen amputations of the leg were treated antiseptically without a death, and nineteen treated in other ways with four deaths. In going into the causes of death, the author concludes that in neither case can the deaths be attributed to the method of dressing employed. Nevertheless, he thinks that the advantage is decidedly with the cases treated antiseptically, on account of the rapid healing, the absence of fever and of suppuration, and the rarity of the dressings in these cases. He mentions the occurrence of aseptic fever in a few cases, and, with Edelberg, he attributes this to absorption of blood from the wound.—*Lond. Med. Record*, Feb. 15, 1881.

Statistics of Congenital Colour-blindness in Denmark.

Dr. O. E. de Fontenay has explained (*Nordiskt Medicinskt Arkiv*, vol. xii., 1880) the progress which has been made in Denmark as to the relations existing between daltonism and the practical pursuits of life. The authorities have carefully examined all the persons engaged on the railroads in order to ascertain the proportion of daltonians (the colour-blind), and all candidates for employment on the lines are hereafter to prove that they are endowed with an adequate sense of the perception of colour. These requirements, however, have not yet been sanctioned by law in reference to the sailors of the navy or the merchant service, except so far that candidates of the school of naval officers are subjected to an examination such as that just referred to.

The author adopts the classification of cases proposed by Holmgren, namely, into (1) total blindness as to colours, and (2) partial blindness, subdivided into complete blindness to red, green, or violet, and incomplete blindness as to those colours. He gives a complete list of the results of his researches, founded on 217 cases, giving information as to the ages and social position of the persons affected, the colour of their eyes, and the degree and kind of daltonism in each In 9659 cases examined at all ages (beginning at eight), of all classes, and in the whole of Denmark, 217 were daltonians. As to social position, 1001 persons belonging to the superior classes presented 31 with defective vision, or about 3½ per cent., while 3491 of the lower classes (workmen, small artisan, peasants, etc.) gave 134 daltonians, or rather less than 4 per cent. From some of Dr. de Fontenay's researches it would appear that females are less subject to daltonism than males, for out of 176 cases of daltonism only 11 were females, and of 632 females of the upper classes not one was daltonian, and 16 daltonian females were all of the lower classes. Out of 2714 children from eight to sixteen years of age, there were 41 daltonians, of whom 36 were males and 5 were females. Of 215 cases of daltonism, 56 were cases of red-blindness, 24 of green-blindness, and 135 were incomplete cases; whence it follows that in Denmark red-blindness is more than twice as common as that of green. In all the 217 cases of daltonism the author found that the two eyes were equally affected; but as to the relation between the colour of the eyes and the frequency of daltonism, the statistics showed that there was no special relation between the colour of the eyes and the affection in question.

As to the hereditary character of daltonism no very satisfactory or conclusive

results have been obtained. In 34 cases where the family history was carefully examined, heredity was denied in 27. In two of the cases there was a daltonian father, and in both the daltonism of the father was of the same degree and kind as that of the offspring. One of the cases had normal parents, but a paternal uncle, two brothers, and his own son were daltonians. Other similar anomalies were observed, and one case offered four daltonian members in the family, namely, an uncle and a maternal cousin, the mother's grandfather, and a brother.

In another paper on the same subject, by Dr. E. J. Mellberg, the author states that he has examined, by the method devised by Holmgren with coloured wools, 227 pupils of the Helsingfors Lyceum, and discovered among them 10 cases of daltonism, of which 4 were cases of red-blindness, 1 of green-blindness, 2 of violet-blindness, and 3 of incomplete daltonism.—*Med. Times and Gazette*, March 5, 1881.

Bacteria in the Choroid.

The *Centralblatt für prakt. Augenheilk.* for October last contains a paper by the DUKE CHARLES of Bavaria on the discovery of bacteria in the choroid coat of two eyeballs. The eyeballs, which showed neither naked eye nor microscopical evidence of disease, were preserved in Müller's fluid. On examination the vessels of both the coarser and the finer vascular network of the choroid were found closely packed with bacteria. They were especially abundant in the larger capillaries just before their ultimate divisions and in the finest capillaries themselves, and least numerous in the small arteries and veins. There was no sign of decomposition of the eyes, nor were any organisms found in the Müller's fluid, in which they had been immersed, while other globes contained in the same vessel did not present any similar appearances. These, together with the fact that the bacteria were only in small numbers in the veins and closely packed in the capillaries, negative the supposition that they had originated *post-mortem*. The bacteria were cylindrical rodlets about half the length of the nucleus of a leucocyte, with a clearly defined outline, homogeneous, glistening, and structureless contents. Besides these, some bacilli from five to twenty times their length and some of the small rods undergoing division were found. They mostly resembled the forms of organisms seen in septic diseases and in decomposition, and they differed from the bacilli of splenic fever by their greater thickness and the slight rounding of their ends.—*Lancet*, Jan. 29, 1881.

—

Treatment of Cancer of the Tongue.

In the December number of the *Bull. et Mém. de la Soc. de Chir.*, is a report of a communication by M. VERNEUIL on the inutility and danger of any save operative treatment of epithelioma of the tongue. This disease, it is pointed out, has never been cured either by internal treatment or by topical applications. M. Verneuil states that he seldom meets with a case of lingual cancer which has not previously been treated by iodide of potassium. Such treatment, it is argued, cannot be justified. It is a gross error to think that iodide of potassium has any efficacy in instances of true neoplasm, for, as is well known, this agent effects no amelioration in cancers of the lip, cervix uteri, and other organs. The diagnosis of epithelioma of the tongue, in the majority of cases, should not be difficult; and, through the recent teaching of M. Fournier, this affection may be readily distinguished from tertiary glossitis. There are, it is true, hybrid cases in which the cancer occurs in a subject of old syphilis, and in which the objective characters of the epithelioma are modified by the constitutional affection. This condition does not indicate any alteration of treatment, for the hybrid affection in its

course, termination, and prognosis, resembles pure epithelioma, and should be dealt with in a like manner. M. Verneuil asserts that medicinal treatment of cancer of the tongue is not only fruitless, but also hurtful. Surgical removal of the disease is postponed, and so much precious time is lost. Iodide of potassium often excites troublesome and obstinate glossitis, and mercury stimulates the growth both of the primary epithelioma, and of any affected cervical glands. Chlorate of potash is as useless in cases of cancer of the tongue, as it would be if given for the relief of cancer of the cervix uteri. Epithelioma of the tongue, M. Verneuil holds, if taken in time, may be cured by operation. Mention is made of four cases of complete cure. In three of these cases the growth was small and superficial; in the fourth case a relapsing growth, together with a degenerated gland, was removed. When more than a third of the tongue has become involved, when the floor of the mouth is also affected, and when the disease has been progressing for longer than a year, the case is deplorably grave, and cannot then be treated by operation with any chance of success. Removal of lingual cancer, it is asserted, is not a serious operation when it can be performed by the mouth, and when the disease is recent and not extensive. Of two hundred such operations performed under these conditions by M. Verneuil, one only was fatal; and, in this instance, the death was due to pneumonia, and not directly to surgical action. Operation at an early stage of the disease is strongly recommended; and it is stated that between the early and favourable stage, and the advanced and hopeless stage, there is a long interval, at any period of which the surgeon may operate without risk, and with some prospect of permanent success.—*London Med. Record*, Feb. 15, 1881.

—

Extirpation of the Pylorus.

Prof. BILLROTH makes the following contribution to the *Wiener Medicinische Wochenschrift* (Feb. 5):—

"We to-day register a triumph which surgical art has recently been enabled to celebrate. The important question which has so long engaged the attention of surgeons—whether the carcinoma which so frequently attacks the stomach, and for which all internal remedies are useless, may not be made amenable to operative surgery—would seem to be at once decided affirmatively. On January 29, Prof. Billroth performed a partial excision of the stomach on account of advanced carcinoma of the pylorus, which up to the present time has been attended with success. Already, seventy years ago, Karl Merrem had shown in a dissertation, by experiments upon dogs, that the pylorus might be excised, and recommended the procedure in incurable cancer. The conviction, however, that the vital processes in man and animals were the same, was as yet too little assured, and operative procedures too little advanced, for the operation to be ventured on. It is only during the last ten years that essential progress has been made in this province of surgery; and Billroth and his pupils have done much in that time to prepare the way for the operation. After Billroth had shown, in 1871, that portions of the œsophagus may be cut out in dogs, Czerny first performed this operation in man. Then followed Gussenbauer's and Winniwarter's excision of portions of the intestinal canal and stomach in dogs, and Martini and Gussenbauer's successful excision of a sigmoid flexure that had undergone cancerous degeneration. Gastrorraphy, successfully performed by Billroth in 1877, was another step in advance, and led him to make the remark that from this operation to the excision of a cancerous portion of the stomach required but one bold step. The first, however, who performed excision (in 1829) for cancerous pylorus in man was the Parisian surgeon Péan, so well known for his numerous laparotomies,

but the patient died on the fourth day; and no suitable case came under Billroth's notice until the present one.

"The woman upon whom the operation was performed on January 29 was forty-three years of age, and previously in good health, having borne eight children. In October, 1880, she suffered from vomiting, and soon presented all the symptoms of carcinoma of the stomach and stenosis of the pylorus. During the six weeks prior to the operation the constant vomiting and the small amount of nourishment taken led to excessive pallor, emaciation, small and frequent pulse, and exhaustion; so that the patient, feeling her end approaching, consented to the operation proposed by Billroth. The preparation for the operation, which was performed in a temperature of 24° R. (86° Fahr.) under chloroform, consisted only in washing out the stomach with the ordinary tube. An incision about eight centimetres in length was performed over the tumour, which was readily movable under the thinned integuments. The tumour proved to be a nodulated carcinoma of the pylorus, which was in part infiltrated, and occupied more than the lower third of the stomach. The parts were carefully separated from the omentum and transverse colon, and, the vessels being tied before their division, very little blood was lost. The tumour having been completely brought on to the integuments of the abdomen, an incision was made through the stomach one centimetre beyond the infiltrated part—first only backwards, and then through the duodenum. An oblique incision through the stomach was next directed from above and inwards to below and outwards, always at a distance of one centimetre from the infiltrated parts. After uniting the oblique incision only sufficiently to allow of its being adjusted to the duodenum, the tumour was completely separated from the duodenum, one centimetre distant from the infiltration, by means of an incision parallel to that made in the stomach. The duodenum was adapted to the aperture left in the stomach, about fifty sutures of carbolized silk in all having been employed during the operation. After cleansing with a 2 per cent. carbolic acid solution, and the application of a guard-ligature, the parts were replaced in the cavity of the abdomen. The operation, including a tedious chloroformisation, occupied one hour and a half. The excised portion consisted of fourteen centimetres of the greater curvature of the stomach, and a quill could only be passed with difficulty through the pylorus. The form of the stomach was not essentially changed by the operation, the organ only being rendered smaller. After the operation there was neither vomiting nor pain. . . . From a communication of Prof. Billroth on February 13, it appears that the patient had continued to improve, so that the recovery then seemed assured. The result is indeed favourable beyond all expectation, and already suffices to show that such an operation is practicable, so that persons may now be successfully treated for a disease hitherto reputed incurable; and even when a relapse takes place, they will at least have received temporary alleviation."—*Med. Times and Gazette*, March 5, 1881.

—

Excision of the Initial Syphilitic Sclerosis, and on the Treatment of Syphilis.

In the *Weiner Med. Presse*, Nos. 27, 28, 29, 1880, Professor Zeissl opposes the view that the initial sclerosis is only a local symptom whence the general infection takes place; he believes the initial lesion to be the first expression of the general infection of the patient's system. The author also relates five cases of excision of indurated sores, in all of which general syphilis followed, notwithstanding the removal of the initial lesion. In the treatment of syphilis the author speaks favourably of Zittmann's decoction, but states that he has not found benefit from pilocarpine.—*Lond. Med. Record*, Feb. 15, 1881.

Suprapubic Operation of Lithotomy.

Dr. PETERSEN (*Archiv für Klin. Chir.*, Band xxv. s. 752) considers that the dangers of the high operation for stone, which consists in injury of the peritoneum and infiltration of urine, may be prevented by modern methods of operation. He has found, by observation on eleven bodies, that when Braune's method is followed by the gradual distension of the rectum, the full bladder is dragged further forward and upright, and the peritoneum thus rises considerably with its anterior fold, much more so than when this is not the case. Petersen, therefore, has recently always operated in such a manner that he not only fills the bladder to the utmost, but the rectum also, by the introduction of a rectal tube, and the gradual injection of water of the same heat as the body, so as to dilate it. In his last two operations, Petersen did not even see the peritoneum; while, in his earlier operations, he was obliged to push it upward. He considers that the danger of infiltration of urine may be overcome by careful suture of the bladder with fine catgut, under complete antiseptic precautions. The special indications for the high operation he sets out as follows: (1) The presence of a large hard stone; (2) encapsuled stone; (3) stone in diverticula, behind the prostate gland; (4) enlargement of the prostate gland; (5) hæmorrhoids; (6) fat subjects; (7) tumours of the bladder; (8) impermeable stricture (with the assistance of posterior catheterization).—*London Med. Record*, Feb. 15, 1881.

—

Simultaneous Ligation of Carotid and Subclavian for Aneurism of the Arch of the Aorta.

A case of successful ligature of the right subclavian and right common carotid arteries simultaneously, for aneurism of the arch of the aorta, under the care of Dr. J. MANSERGH PALMER, surgeon to the Armagh County Infirmary, deserves record. The patient, a woman aged fifty, was admitted to the hospital on Feb. 10th, 1880, having noticed a slight swelling close to the right sterno-clavicular articulation during the previous November. On the night of the 12th Dr. Palmer found her suffering from great difficulty of breathing, stridulous respiration, lividity of face and neck, coldness of extremities, and other symptoms which rendered an immediate operation absolutely necessary. She was removed to the operating room, the right common carotid artery was tied, and as the tumour did not appear to decrease and pulsation continued, the subclavian was also ligatured. On the 29th the carotid ligature came away, and on March 2d the subclavian. On April 27th she left the hospital, both wounds being quite healed. Early in June she caught cold and was readmitted to the Infirmary, but refused to take any medicine. On June 14th hemorrhage took place from the old cicatrix in the neck over the carotid vessel, being complicated with hæmoptysis, which also occurred on the following day, and on the 10th there was profuse hæmoptysis and death supervened 125 days after the operation. A post-mortem examination showed that the aneurism involved not only the arteria innominata, but also the arch of the aorta, while at the posterior and left side of the arteria innominata was an opening communicating with the left vena innominata, which latter communicated with the trachea at one point and at another opened into the right lung.—*Lancet*, March 5, 1881.

—

Three Cases of Knee-joint Abscess in Children.

Mr. EDMUND OWEN, Senior Assistant-Surgeon to St. Mary's Hospital, at a late meeting of the Medical Society of London (*Lancet*, Feb. 12, 1881), exhibited three patients who happened to have been lately under treatment

together, and are, indeed, the only instances in which he has recently had occasion to open the knee-joint for suppurative arthritis. Short as the series is, these cases offer, he thinks, "an interesting subject for discussion and criticism; and especially so as you have just had the opportunity of examining the present condition of the joint in each instance. The eldest child only was treated by me as an in-patient; the others were brought as out-patients to the Children's Hospital.

"Briefly, the line of treatment has consisted in free incisions into the joint and subsequent free drainage; in absolute and prolonged rest of the limb with compression of the articulation; in constitutional and dietetic support, and (need I say it?) in local cleanliness. But having remarked that I have employed cleanliness in the treatment of these diseased and opened joints, the conclusion that I adopted the high ritual of spray and the vestments of gauze would be both hasty and inconsequent. I wish it, however, to be thoroughly understood that I did my best to keep the articulations clean, both on the exterior and in the interior. I would like it to be understood also that by no means do I bear the spray and gauze ill-will; I even look upon them as a kind of safety-lamp which may well be carried by those who work in an atmosphere of surgical fire-damp, as well as by those who, trespassing in the seductive regions of speculative surgery, may on occasion require evidence of their having started on their excursion without neglect of approved precaution. To the great champion of cleanliness in our art I personally owe a boundless debt of gratitude, but to certain of his enthusiastic disciples who, to speak within bounds, seem to consider those who do not adopt their creed as wilfully obstinate or morally oblique, I will delicately put this question: Could any other method of treatment have obtained better results than those which we have now before us?

"Our medical journals are continually called upon to publish reports of cases, trifling and serious, which have recovered after 'antiseptic treatment,' that this short series out of the groove cannot now but be of interest. Possibly even they may help to show that *post* and *propter*, when employed in connection with a certain surgical practice, need not be confused even when half-obscured in a cloud of carbolized vapour.

"The first case is that of a girl of about four years of age. A little more than two years ago she was brought into the out-patient room in Great Ormond Street in a most pitiable condition. The left knee was red and enlarged from a collection of fluid in the interior. So painful had the joint been that appetite and sleep had left her. Moreover, she had had several attacks of convulsions—the rigors of childhood. Ten months previously, the mother said, the child had fallen off her chair, and directly afterwards the knee had begun to swell; but though the swelling had steadily increased, the child had been able to limp about until three weeks ago. The whole limb was red and swollen. She was at once put to bed, and the Registrar (Dr. Abercrombie) going round next morning noted that the leg and thigh were the seat of erysipelas, and that there were several blebs on the leg. The glands in the groin were enlarged and tender. Though there was a small sinus leading towards, or into the joint, from the inner side, from which a thin fluid was oozing, the patella was floated from off the femoral condyles. The temperature was just under 101° Fahr. On the third day after her admission—that was when I next saw her—chloroform was administered, and a free incision was made on each side of the knee, much thin pus escaping. The finger passed into the interior of the joint detected much thickened and pulpy synovial membrane, but no diseased bone. The joint having been thoroughly washed out with a weak solution of chloride of zinc, a drainage-tube was passed through it, and the limb was put up again on a slightly bent tin splint.

Nevertheless, the erysipelas continued to advance, and blebs now had made their appearance on the thigh, and the temperature went up two or three degrees. The child was taking quinine, iron, and wine; in less than a week the temperature began to track the chart along the normal line. For convenience in the washings, which were daily performed by the house-surgeon, Mr. Kempe, the back splint was changed for extension by the stirrup, weight, and pulley. A month after her admission the joint was strapped, the drainage-tube still lying in the outer wound; and at the end of another like period she was taken home in excellent condition, the wound, though steadily closing, still weeping a little. But at home she did not prosper, and in three weeks she was again in hospital for ten days. Since that time she has steadily improved, the limb being fixed upon a back tin splint. It is no exaggeration to say that in function and movement the damaged knee is now as good as the other. The child runs about on it all the week, and kneels upon it on Sundays. It is absolutely free of pain.

"The second case is that of a little boy. The mother says that the disease was started by a fall out of bed upon the knees, after which the right joint began to swell. At the beginning of last year he was sent to me by Dr. Goullet, of St. John's Wood, for an attack of subacute synovitis. The child was then under a year and a half old. We fixed the limb on a tin splint, and Dr. Goullet looked after the child until April, when, in spite of the treatment adopted, the inflammation had run on to suppuration. In this case only one incision was made into the joint, and that on the inner side. The solution used for washing was weak tincture of iodine. Three days after that operation it was noted that the child had lost its thirst, and that its nights were quiet. Previously it had been in the habit of starting in its sleep and awaking with a scream. Seven months later it was remarked at the side of the prescription-paper, under the date of Nov. 17: 'Has been wearing the splint up to to-day. The wound has healed, but there is a good deal of eczema around its site. There is good flexion and power of movement in the joint, but there is still some fulness about the ligament of the patella from the old thickening of the synovial membrane. The health is excellent.' There is no tenderness at the knee, which can be bent, without disturbing the child, to less than a right angle. Though the skin over the old wound is not sound-looking it is serviceable enough, and the child cruises about the room without inconvenience.

"The last case is that of a baby of four months, who was brought as an outpatient from Hendon at the end of last June. Against his name in the case-book I then wrote: 'Subacute synovitis of the left knee-joint,' and fixed the limb on a bent splint with strapping and soft bandage. But by the tenth day it was evident that a purulent collection occupied the synovial pouch. Excessive pain in the part had driven away sleep, and the child had attacks of convulsions. The knee was red, hot, swollen, and very tender. By means of incisions, and injections of weak tincture of iodine and water, much thin sero-purulent fluid and flakes of thick and curded pus were washed out of the joint, and the limb was then packed round with vaseline lint and tenax, and fixed to a splint. Gradually the splint was straightened, and by the middle of September drainage was discontinued, and the wounds healed up. The child never had a bad symptom. In October last there was free movement in the joint, and the infant was flourishing; and, as you have seen to-night, the child allows full examination of the capabilities of the joint to be made. He even flexes it of his own accord; and, his mother says, tries to walk on it.

"I am well aware that there is nothing of an extraordinary nature in these reports and cases, unless it be the simplicity of the treatment adopted. A treatment somewhat similar to that described by Mr. Sampson Gamgee (*On the*

Treatment of Wounds, p. 101), with this exception—improvement, I will call it—that the pus is straightway washed out of the joint, instead of being allowed to ooze out. So the joint gets a well-considered and fair start towards the goal of recovery.

"In conclusion, I will venture to express the opinion that the chief requisites for obtaining such happy results in the treatment of acute joint-abscess in childhood are the early employment of clean and free drainage and the prolonged continuance of absolute rest. And these are conditions which are fortunately very generally obtainable."

A Case of Gangrene of the Arm from a Poisoned Wound—Amputation at the Shoulder, and Recovery.

Mr. HEATH reported this case at a recent meeting of the Clinical Society of London (*Med. Times and Gazette*, Feb. 26, 1881).

The patient was a nurse, aged thirty-four, who, in laying out the body of a lady who had died of puerperal septicæmia, pricked her thumb with a pin. Notes of the puerperal case were given by the physician who had attended her, and it appeared that she was a primipara in good health, and was the first patient attended by the accoucheur after his holiday, and that strict antiseptic precautions were employed. On the fourth day a rigor occurred, and the temperature was 105°, pulse 120. Subsequently the temperature went up to 107°, but was reduced to 102° by an ice-cap and water-bed. On the seventh day, however, the left pleura filled, and the patient sank. A nurse in attendance pricked her finger on the day of the rigor, and had a sharp attack of lymphangitis, with recovery. The second nurse carried out the attendance till the patient's death. This nurse applied nitrate of silver to the puncture on the evening of the day she received it, and the next day the hand was swollen and painful. She had no further advice until the fourth day, when she was admitted to University College Hospital with the whole arm swollen and tense. Free incisions were made, but the next day the hand and forearm had gangrened. At first, the gangrene seemed limited to the forearm, and the swelling of the upper arm decreased for a few hours, but a relapse taking place, Mr. Heath amputated at the shoulder-joint. The patient made a rapid recovery, and was discharged in a month. Mr. Heath remarked upon the virulence of the puerperal poison, and protested against the common practice of applying nitrate of silver to punctures received at post-mortems. He believed that the application of belladonna was most useful in cases of local inflammation, coupled with free incisions when necessary.

Mr. HARRISON CRIPPS gave the history of the case referred to by Mr. Heath as occurring in St. Bartholomew's Hospital. The patient was under the care of Mr. Holden, and was both healthy and temperate. He had pricked his finger very slightly; next day it began to swell, and when seen the arm was black as far as the wrist, the forearm was red. Free incisions were made in the hand, but only a little clotted blood and serous fluid came away. The swelling and redness rapidly extended upwards. It was consequently determined to amputate through the shoulder-joint, but some diseased tissue had to be cut through. Next day the temperature had fallen and the pain gone. Six days afterwards there was a severe rigor, and the neck swelled. This was punctured, but nothing came away; his face subsequently became gangrenous, and the man died. In Mr. Heath's case recovery was no doubt due to early operation. It would be important to know when and where to operate in such case.

Mr. LISTER thought the cases only tended to confirm the old rule to operate at once in a case of spreading gangrene. In these cases there was probably an

organism at work, as in the case of the *Bacillus anthracis*. But in some the blood was specially affected, or, as in Mr. Heath's case, the tissues.

Mr. HEATH said, in reply, that the rule was not only to operate early in these cases, but also to operate high up.

—

The Treatment of Malignant Pustules.

M. VERNEUIL, in an important communication to the Académie de Médecine on this subject, reminded his hearers that the malignant pustule consists of three zones or regions: first, the slough or gangrenous zone with its characteristic vesicles; secondly, an indurated zone presenting on its surface other vesicles; and, lastly, the zone of œdema. Until recently surgeons have concentrated their attention on the central or gangrenous zone, have applied almost no treatment to the indurated zone, and always none to the zone of œdema beyond poulticing and leeching. According to M. Verneuil it is important to apply to each zone special and energetic treatment. These are—first, to destroy or excise the gangrenous part; secondly, to incise and cauterize deeply the zone of induration; thirdly, to disinfect, by antiseptic hypodermic injection, the zone of œdema; lastly, to employ general antiseptic treatment, such as the internal administration of iodine or some other efficient internal antiseptic. The experiments of Davaine have shown that iodine, even in small doses, has an efficient neutralizing action on the virus of anthrax, and it is possible, according to M. Verneuil, to introduce into the circulation a sufficient quantity of iodine to produce this effect. The hypodermic injections into the œdematous zone should also consist of iodine, ten drops of a one-half per cent. solution. The first case thus treated was one of malignant pustule on the arm, in which the actual cautery had failed, and amputation was contemplated; the treatment was perfectly successful. In another case the pustule was situated on the eyelid, inoculation having been effected by inadvertently scratching a pimple there. The eyelid was much swollen, and presented the characteristic vesicles and bullæ, and there was considerable œdema of the whole of that half of the head. The temperature was 103°; the patient was delirious, sleepy, and vomited continually. The pustule was destroyed by means of the thermo-cautery. In the zone of induration a series of punctiform cauterizations were made with the same instrument, to a depth of one-third of an inch, and then the solution of iodine was injected in the œdematous part at intervals of five centimetres. The temperature rapidly fell. The delirium, somnolence, and vomiting ceased as if by magic, and on the third day the patient was out of danger. In the discussion which followed M. Léon Labbé agreed with M. Verneuil as to the necessity of cauterization in the zone of induration, and employed it even in the œdematous region. He was inclined to attribute more importance to this measure, employed in an energetic and even, as it might seem, barbarous degree, than to the injections of iodine. M. Gosselin urged the importance, before applying the treatment to every pustule which had a malignant aspect, of ascertaining if it were really anthrax, by microscopical examination of the serum in the vesicles and of the blood. M. Verneuil, speaking from the standpoint of practical surgery, maintained that better indications could be drawn from the clinical aspect of the affection than from the presence or absence of bacteria. He had seen cases in which bacteria were found in the vesicles and in the blood, although the symptoms were benign, and others in which, in spite of the absence of bacteria, the augmenting gravity of the affection necessitated the use of the most energetic remedies.—*Lancet*, Feb. 19, 1881.

Midwifery and Gynæcology.

The Distance between the Fontanelles as an Index of the Size of the Fœtal Head.

Dr. J. MANDELSTAM has published in the *Archiv für Gynäkologie* the results of an investigation into the relation which the distance between the anterior and posterior fontanelles bears to the other dimensions of the fœtal head. This measurement—viz., the distance between the fontanelles—is one which may be estimated before the head has entered the pelvis; and if its relation to the degree of ossification and the size of the head be constant, it is obvious that it may be made to give us information of great value in deciding as to the best course to follow in the management of a particular labour. Fehling has shown that there is a relation between the size of the anterior fontanelle and the horizontal circumference of the head; but this knowledge is of little use in practice because the over-lapping of the bones during labour alters the size of the fontanelle. It has also been shown that there is a relation between the distance from the anterior to the posterior fontanelle and the length of the child; but the latter is not a very important factor in the mechanism of labour. Dr. Mandelstam has therefore set himself to ascertain whether the distance between the fontanelles bears the same constant relation to those diameters of the fœtal head upon which the ease or difficulty of delivery chiefly depends. As yet he has only commenced the subject. He very properly approached the problem in its simplest form. He measured children's heads three or four days after birth, when the overlapping of the bones and swelling of the soft parts had had time to disappear. He has examined ninety-eight heads, and the results lead him to the following conclusions: That there is a direct proportion between the development of the child and the size of its head, on the one hand, and the distance between the anterior and posterior fontanelles, on the other; if the distance between the fontanelles be great, a large head and a well-developed child may be expected. Should a larger number of observations confirm this statement, we shall have, in the distance between the fontanelles, a datum from which to judge of the amount of mechanical hindrance to delivery which the child will offer; and in the present uncertainty of all other criteria, this is not to be underrated. How far it is possible, at the bedside, to properly measure this distance, Dr. Mandelstam at present refrains from stating; but he believes that a practised accoucheur can in many cases, even when the head is high up, feel the sagittal suture in its whole extent, and therefore form a tolerably accurate judgment upon its length. We feel sure that all who are interested in obstetrics as a science will agree with Dr. Mandelstam as to the uncertainty attending the judgment we are at present able to form, in the early stages of labour, as to the size and compressibility of the head; and we hope that he will continue his researches, and give us definite criteria by which to go.—*Med. Times and Gazette*, Feb. 19, 1881.

Pregnancy and the Acute Infectious Diseases.

A recent clinical lecture of Dr. RUNGE has been devoted to a recapitulation of what is known as to the mutual relations of pregnancy and the acute infectious diseases. It may not be without interest and instruction to our readers if we glean from Dr. Runge's lecture its most important points.

The frequency of abortion, or premature labour, in the acute infectious diseases varies according to the disease (the prognosis for the child being worst in smallpox and in cholera), the character of the epidemic, and (especially in typhoid fever) the treatment. The process of abortion is much the same as

when it takes place from other causes, except that in some diseases, notably typhus and smallpox, there is apt to be unusual hemorrhage. In the later stages of pregnancy, premature delivery is generally without complications.

In considering the causes of fœtal death in these cases it must in the first place be asserted that none of these diseases have any special lethal effect upon the fœtus. The death of the infant is due to the concurrence of a number of unfavourable conditions, some of which we know, others we do not know. First, the effect of temperature. In all conditions attended with fever the fœtus runs a risk which is proportional to the height and duration of the pyrexia; and where these are extreme, it dies from what may with accuracy be called "heat-stroke." As the mother's temperature rises, the beats of the fœtal heart increase in frequency, and the child's movements become more active. A maternal temperature of 42° or 42.5° C. (about 108° Fahr.) appears to be absolutely fatal to the child. Risk begins at 40° C. (104° Fahr.). Dr. Runge has confirmed these clinical observations by experiments upon animals.

Next, the effect of asphyxia. It has been clinically ascertained that in diseases interfering with the respiration or circulation the fœtus often dies, and its death is preceded by retardation of the heart's action and discharge of meconium —signs which indicate death from asphyxia. Dr. Runge has performed some experiments on animals which afford exact demonstration of the fact that fœtal asphyxia is thus caused. He opened the abdomen of a pregnant rabbit, and took out one or more embryos, inclosed in their membranes and with their placentæ, and put them in a solution of chloride of sodium. Then, having closed the uterus and abdomen, he killed the animal by suffocation. He found that the embryos which had been taken from the mother and put in the chloride of sodium solution, lived; while those still in connection with the mother while she was being suffocated, died. The inference he draws is, of course, that those taken out of the mother and put in the saline fluid were simply deprived of oxygen, and recovered when oxygen was given them; while those retained in connection with the mother were not only deprived of oxygen, but were poisoned with carbonic acid. It has been found clinically that great anæmia leads to fœtal death. This is due to deficiency in the supply of oxygen.

The third condition which helps to bring about fœtal death is the direct transmission of infectious matter from the mother to the child. This is not so satisfactorily proved as could be wished. All the experimental investigations that have been made tend to show that no molecular contagion can pass the walls of the placental villi. In relapsing fever, for instance, the spirillum is never found in the fœtal blood, and mothers suffering from this disease often bear healthy children. On the other hand, patients with variola have borne children suffering from the same disease. It has also been asserted that when women advanced in pregnancy have been successfully vaccinated, the fœtus has proved insusceptible to the vaccine virus. This, however, needs further confirmation. Mothers suffering from ague have sometimes borne children with large spleens. With these exceptions, there is no evidence of the transference of any acute infectious disease from mother to child. Even in these such communication is rare.

As to the fourth mode in which these diseases affect utero-gestation—viz., by causing changes in the placenta—little is known. Changes in the endometrium occur in cholera and in typhus, and it is to be presumed that were a patient pregnant such changes would affect the placenta.

The conditions which lead to the premature expulsion of living children in these diseases seem to be the same in kind as those which in some cases lead to fœtal death. It has been found, by experiment, that deprivation of oxygen, or cutting off the blood-supply, leads to uterine contraction; and that prolonged

pyrexia also increases the irritability of the uterus. The reason why in some cases the fœtus dies, but in others is expelled prematurely, though living, appears to be, that where the injurious conditions mentioned rapidly reach a great height, the fœtus is killed; but where their onset is slow, the infant is expelled before the state of things has become such as is incompatible with its vitality.

Hemorrhage into the decidua or placenta will occur to most as a probable cause of abortion in such diseases as are associated with a tendency to hemorrhage. But there is this difficulty about admitting it to be such: that we cannot yet separate the cases in which hemorrhage is a cause from those in which it is a consequence of abortion. Hemorrhagic inflammation of the endometrium, leading to destruction of that tissue, has been found by Slavjansky after death from cholera.

Dr. Runge concludes his lecture with a plea in favour of the experimental method of studying physiology and pathology, and laments that the majority of those engaged in the study of obstetrics and gynæcology busy themselves more with operative technicalities than with the microscope, with chemical analysis, or with the vivisector's knife. It is to be regretted that sentimental legislation obliges English workers in this and other fields to depend upon other countries for the invaluable information which is only to be obtained from experiments on living animals, and of which the experiments of Dr. Runge that we have just quoted are a sample. Dr. Runge's work cannot fail to be fruitful in practical results. He indicates some; but as they are only suggestions we refrain from quoting them.—*Med. Times and Gazette*, Feb. 26, 1881.

Spinal Paralysis in New-born Children.

LITZMANN has contributed to the *Archiv für Gynäkologie* a valuable paper on the above obscure subject. Attention was first drawn to the occurrence of deformities due to spastic rigidity of more or less extensive groups of muscles, and probably caused by lesions of the central nervous system during delivery, by Dr. W. J. Little. His cases, however, were mostly those of children from one to ten years of age, and therefore it was impossible for him to make any precise statement as to the cause or nature of the initial lesion. Since then little has been done at the subject. Litzmann records a case of his own, in which a full-term child presented by the feet in a slightly contracted pelvis. Some traction on the foot was needed to effect delivery. When this traction was begun, the reflex movements of the leg were active; but while it was being pulled upon, a slight cracking sound was twice heard, and the reflex irritability of the foot ceased. The child was born living; but both lower extremities were found to be paralyzed. On the tenth day movements of the toes were perceived. About two months after delivery, reflex irritability and sensation began to decidedly, though slightly, return; but talipes varus, which was present slightly after delivery, became more marked. No treatment was carried out (owing to the objections of the parents) till the child was eight months old. Nevertheless, movement and sensation gradually returned. At this age treatment by faradization was begun, and regularly carried out; but although the child continued to improve, yet the amelioration was not so rapid as to indicate a marked effect from the treatment. Dr. Litzmann believes that in this case the symptoms were due to a lesion of the lumbar enlargement of the cord produced during delivery. He refers to cases published by Seligmüller, Hennig, and Mauthner, which resembled his own in that there was paralysis following birth, and the children recovered. He also quotes others in which an autopsy was made. Parrot has published a case in which the spinal cord was found ruptured without discover-

able injury of the spine. Gueniot and Ahlfeld record cases in which the spine was fractured. Ruge, out of 64 cases of delivery by the feet, found fracture of the spine in 8, mostly in the dorsal or cervical regions. Litzmann believes that in his own case the lesion was probably hemorrhage into the vertebral canal, due to disturbance of the circulation from pressure on the cord. He states that out of 161 autopsies on newly born children made in his clinique, the vertebral canal was opened 81 times, and in 33 of these hemorrhage into the canal was found, in 19 cases the extravasations being of considerable amount. In 23 the blood was wholly external to the dura mater, in 4 also in the arachnoid sac, and in 1 also in the sub-arachnoid space; it was 4 times only in the arachnoid cavity, and once only in the sub-arachnoid space; in none was there any injury to the canal itself. In the cases in which the blood was found in the arachnoid and sub-arachnoid cavities, there was also intra-cranial hemorrhage: 23 of these children were full term, 10 premature; 13 were born dead, and 20 (15 at term, 5 premature) were born alive—all of them head-presentations; 5 of these died within twenty-four hours (4 of them being premature), 12 between the second and tenth day, and the others at the fifteenth, sixteenth, and twenty-eighth day respectively. Extravasations in the substance of the cord were never found. Billard, however, has described changes (softening and disorganization) of parts of the brain and spinal cord in newly born children who were paralyzed.—*Med. Times and Gazette*, Feb. 26, 1881.

—

Vaginitis Exfoliativa and Dysmenorrhœa Membranacea.

Vaginitis exfoliativa, or exfoliation of the epithelial lining of the vagina, is not an affection frequently observed; yet several cases of it have been recorded, and in some of these it was associated with membranous dysmenorrhœa. In a paper in the current number of the *Archiv. für Gynakologie*, Dr. COHNSTEIN describes an interesting case of this disease which was associated with severe dysmenorrhœa, but apparently not of the membranous kind. The chief interest of the paper, however, lies not in this case, but in the part of it devoted to membranous dysmenorrhœa, and more especially in the attempt therein made to explain the etiology of this form of menstrual disorder. Like most disorders of which we possess little real knowledge, membranous dysmenorrhœa has been the occasion of much theorizing, rather more theorizing than observing—some of it baseless and purely fanciful, and some of it with a show of reason. The attempt made in the paper referred to is quite refreshing in these days, when attention is concentrated upon local changes and mechanism, for it looks for the cause of the disease, not in the uterus or ovaries themselves, but in the general conditions of the system. Indeed, the author maintains that membranous dysmenorrhœa is not the result of local changes but of general disease. In support of this view he brings forward, in the first place, reasons for not regarding membranous dysmenorrhœa as a local affection. They are: 1. In by far the greatest number of cases of metritis, chronic catarrh of the uterus, tumours, etc., there is no expulsion of membranes. 2. Women who present no discoverable change in the sexual organs suffer from membranous dysmenorrhœa. 3. Of sixty-two cases collected, the author finds general disorders three times more frequent than local disease. 4. Cases are known in which a decidua menstrualis has been extruded without suffering. Such cases indicate that a general cause brings about the condition, and dysmenorrhœa is often only incidental. 5. Local treatment of membranous dysmenorrhœa is usually not followed by any good result; sometimes it produces more evil than good. Having given the above reasons for regarding dysmenorrhœa membranacea as not the result of local change, the author proceeds to give his

reasons for believing in a causal connection between hysteria and the disorder, and they are the following: 1. The frequent coincidence of a slight degree of hysteria with nervous dysmenorrhœa. 2. Dysmenorrhœa membranacea is not rarely associated with hereditary troubles. 3. In the course of hysteria the most various anomalies of secretion and excretion occur. 4. The occasional complete disappearance of the membrane, and its return after longer or shorter intervals; such irregularity cannot be due to a disorder of the genital organs. 5. The vaginismus and the suffering lasting through or only coming on during the intermenstrual interval, without apparent disease of the sexual organs. 6. In sixty-two cases collected by the author, in twenty the expulsion of membranes was said to be due to a local cause, while in forty-two it was ascribed to general disorders—as hysteria, anæmia, chlorosis, chronic dysentery, etc. Heartily sympathizing as we do with the author in his attempt to elucidate the etiology of membranous dysmenorrhœa by having recourse to a wider base than the sexual organs, yet we cannot help feeling that with two exceptions the two sets of reasons given—those against regarding the disease as of local, as well as those for regarding it as of general origin—have no bearing upon the question. They prove nothing. The two exceptions are:—1. Women who present no discernible change in the sexual organs suffer from membranous dysmenorrhœa. Had we been able to state that women who present no change suffer, the author's first position would be proved, but it is well known that our means of investigation can discover only very coarse changes, while many even of these elude our search. 2. Were it true that two-thirds of the cases are due to general conditions, the author's second position would be a just inference—that is, that membranous dysmenorrhœa is due to general conditions. But, as a matter of fact, the general conditions presented by two-thirds of the cases were not those now described as the causes of the affection. In some of them, it is true, they may have been so described, but by no means in all. So long as our knowledge of the physiology of the female sexual organs remains in a state of uncertainty and doubt, we cannot expect that the pathology of the same structure will be better understood. The investigation both of the physiology and pathology of these organs is surrounded with peculiar difficulties, and this may be excuse enough for some theorizing upon them; but we feel sure that we cannot arrive at a correct pathology until we arrive at a correct physiology, and any theory of the pathology or etiology of the uterus and ovaries which does not start from physiology will prove true, if at all, by accident only. Here we think Dr. Cohnstein has erred, and consequently missed his mark. We think with him that dysmenorrhœa membranacea has in many instances at bottom a general condition for a cause, though we do not believe it to be hysteria; that condition produces dysmenorrhœa by organic changes in the uterus resulting from it, though these changes may elude our means of research.—*Lancet*, Feb. 12, 1881.

—

Chronic Complete Inversion of the Uterus.

Dr. ROGERS, at a recent meeting of the Obstetrical Society of London (*Lancet*, Feb. 5, 1881), related a case of Chronic Complete Inversion of the Uterus, successfully treated by sustained elastic pressure. S. B——, aged twenty-nine, had a child two years ago. Delivery was followed by great flooding, and menorrhagia has continued more or less ever since. On admission a tumour was felt in the vagina, as large as a turkey's egg; a ring encircled its neck, but the sound could not be passed more than a line or two above this. On April 28, Dr. Aveling's double-curved repositor was applied, and adjusted by Dr. Aveling. After twenty-four hours the strings were tightened, the patient being very comfortable. About sixteen hours later she felt great relief; something had given way, and the strings

had become loose. On examination the repositor was found within the uterus hig up, and was removed without difficulty. The uterus was completely restored.

Dr. AVELING stated that, since he invented his repositor last year, five case had been successfully treated by it.

Medical Jurisprudence and Toxicology.

Diagnosis of Blood Stains by the Micrometric Method.

In a lengthy letter to *Gaillard's Medical Journal* (Jan. 1881), Dr. J. G RICHARDSON presents the following summary of the final results of his studi upon the measurement of red blood corpuscles and its bearing upon the diagnos of blood stains.

1st. That in unaltered blood stains as ordinarily produced by the sprinkling drops of blood upon clothing, leather, wood, metal, etc., we can by tinting wit aniline or iodine distinguish human blood corpuscles from those of the ox, pi horse, sheep and goat, wherever the question is narrowed down by the circum stances of the case to these limits.

2d. By the method I have devised we can measure the size of the corpusc and apply the two corroborative tests of tincture of guaiacum with ozonize ether and of spectrum analysis to a single particle of blood-clot weighing le than one fifteen-thousandth part of a grain, a quantity barely visible to t naked eye.

3d. Hence, when an ignorant criminal attempts to explain suspicious blo spots upon his clothing, weapons, etc., by attributing them to the ox, pig, shee or goat, or to any of the birds used for food, we can, under favourable circu stances, *absolutely disprove* his false statement and materially aid the cause justice by breaking down his lying defence, even if twenty years have elapsed.

4th. But if the accused person ascribes the tell-tale blood to a dog, an elepha a capybara, or any other animal in Dr. Woodward's list, it is useless to attem to dispute his story, on microscopical evidence as to the size of the blood co puscles.

5th. In cases of innocent persons wrongfully accused of murder, and rea stained with the blood of an ox, pig, or sheep, testimony of experts found upon measurement of the corpuscles would be valuable, but less conclusiv because under certain circumstances human blood corpuscles may *shrink* to t size of those of the ox, whilst under no known conditions do ox or pig corpusc *expand* to the magnitude of those in human blood.

6th. In order to do away with ingenious objections of lawyers that the mu dered person may have been affected with some disease which altered the size his blood disks, or that the articles of clothing, etc., upon which the stains we deposited had produced chemically or otherwise some similar change in the magnitudes, it is very important to obtain promptly, stains from the fresh blo of the victim made in the presence of witnesses upon portions of the prisone clothing or weapons analogous to those upon which suspicious red spots are fou when he is arrested. When this cannot be done spots of the murdered perso blood sprinkled on white paper, and fragments of his lungs and kidneys shou be carefully preserved, the former by rapid drying and the latter by preserv tion in diluted alcohol. These little precautions, which may in any instance pro to be of infinite importance, should be earnestly impressed upon coroners, distri attorneys, and policemen throughout the civilized world.

MEDICAL NEWS.

The Dangers of Diseased Meats.

At the present time popular attention is so generally aroused to the possiblity of infection from unsound meat, by the promulgation of a French edict against the importation from America of trichinous pork, and the rumored embargo upon our meat in England on account of an imaginary epidemic of "hog cholera," in the Western States, that the moment seems an opportune one for discussing what may prove a far more serious danger to ourselves from diseased animals used as food, viz., the transmission of consumption by the flesh and milk of cattle affected with tuberculosis.

Since it is estimated by competent authorities that only about one-fourth of the cases of phthisis in the human race can be traced to hereditary influence, it has long been supposed by medical philosophers that there must be some unknown predisposing cause to the formation of tubercle, which, acting in concert with the great exciting cause in our climate of atmospheric vicissitude, determines the advent of consumption in many of the instances which go to make up the remaining three-fourths of the mortality from this fatal disease.

The experiments of Villemin and Burdon Sanderson in 1865, seemed to show that (contrary to the previously received opinion) tubercle was easily inoculated, especially upon rabbits and guinea-pigs, but they were, as is well known, corrected by further observations which demonstrated the curious fact that the production of a suppurating wound by the introduction of an inert substance, such as a fragment of paper or India-rubber, beneath the skin of one of these animals, was often followed by general tuberculosis. Some more recent investigations of Prof. Chauveau, of the Lyons Veterinary School, are so devised as to eliminate this disturbing element of a surgical operation, and appear to indicate that tubercle can be readily conveyed by the ingestion of tubercular animal tissues. Chauveau purchased upon one occasion four healthy calves, made them each swallow about an ounce of tubercular matter from an old cow's lung, and repeated the dose to three of them at short intervals. Within a month these three presented a miserable aspect as compared with the fourth, which had escaped infection, and when killed, they showed on post-mortem examination a condition of general tuberculosis, the local lesions of the intestines and mesenteric glands, constituting *tabes mesenterica*, being particularly well marked. The lungs were studded with

caseous nodules and the bronchial glands were involved, but the spleen and kidneys were not affected.

Prof. Orth, of Göttingen, so well known by his excellent work on Pathological Anatomy, has very lately published his opinion deduced from his own experiments, which corroborate those of Chauveau and others, that the transmissibility of tuberculosis from one creature to another in this way is now *proved* to occur, and that it is highly probable human beings have often been thus infected from the brute creation. In Prof. Orth's investigations, out of fifteen animals which were fed with tuberculous material from a diseased cow, nine were infected and four died. Autopsies of the diseased beasts revealed a general tuberculosis of nearly all the organs.

Nor is this dangerous infective property confined to the meat of diseased animals, for Prof. Bollinger, who is associated with Prof. von Pettenkofer in the celebrated Hygienic Laboratory of the University of Munich, asserts that the milk of such creatures has a pre-eminently contagious influence, and reproduces tubercular disease in others to which it is administered. According to his experiments even boiling the milk does not destroy its injurious properties in this respect.

With such a probability as these various investigations establish, that consumption, the most dreaded malady of northern latitudes, and the disease which leads the mortality lists of most large cities, is often propagated by the ingestion of meat and milk from tuberculous animals, it is surely time that energetic efforts should be made by our legislators for the prevention of traffic in food which is so dangerously diseased. Dr. Noah Cressy, V. S., of Hartford, Connecticut, several years since called attention to this important subject, and in a recent paper in the State Board of Health Report ably urges that steps should at once be taken to stamp out the affection from among our cattle, with the reasonable hope that by breeding only from stocks of acknowledged purity, combined with proper sanitary care of the animals (especially the utter abandonment of stall and swill feeding), we might afterwards be able to preserve our herds free from taint of this disease. Of course only the most earnest and persistent trial of this plan could be successful, and in many cases it would probably be advisable to completely destroy the stables which had become infected by sheltering animals suffering from the malady. A necessity for this extreme precaution is indicated by the results of observations made by Dr. Grad, of Alsace, who on visiting a farmer in his neighbourhood was informed that annually for five years one of his cows had died of consumption in a certain stall. In order to test the question of local infection, Dr. Grad, with the consent of the owner, selected a vigorous three-year-old heifer of perfectly healthy pedigree, and placed her in the supposed fatal stall. For a time the animal continued well, but after calving, a slight cough set in and this gradually increased, emaciation took place, until

when inspected a year later the creature was a mere shadow of her former self, and presented all the symptoms of advanced tuberculosis. In this case it is naturally to be inferred that the malady was transmitted by the ingestion of tuberculous matter, which had been coughed up on the stall by animals which had previously occupied it. Nevertheless, it is highly probable that, in some instances at least, the infection is conveyed to a healthy creature from a sick one, especially in the latter stages of the complaint, by inhalation of the breath charged with tuberculous matter. Dr. Tappeiner's experiments, which are very instructive upon this important point, are as follows. He caused eleven puppies to inhale fine particles of tuberculous matter distributed through the air of the room in which they were confined, by the aid of a steam atomizer. Within forty days, when the animals were killed, ten of them showed well-marked miliary tubercle in both lungs, and, although such a series of experiments is alone by no means conclusive, its results are so corroborated by occasional events in the experience of most physicians of large practice in pulmonary diseases, that no system of prophylaxis against phthisis can at present afford to ignore their teachings.

—

Indiana State Board of Health.—A bill has passed the Indiana Legislature authorizing the Governor to appoint a State Board of Health.

—

Treatment of Extra-uterine Pregnancy.—At the meeting of the Medical Society of the County of New York held Feb. 28, 1881, Dr. WILLIAM T. LUSK read a paper upon this subject in which he advocated the use of the faradic current, according to the method proposed by Dr. Allen, of Philadelphia, for the destruction of the fœtus, which he prefers to leave for absorption, unless its presence excite too grave local and general symptoms, when laparotomy, conducted antiseptically, should be resorted to.

—

Index Catalogue of the Library of the Surgeon General's Office.—The final action of Congress, looking to the continued publication of this work, has resulted in the appropriation of $10,000 for the publishing of vol. ii., which will, it is estimated, about cover the cost of type-setting and stereotyping; for its issue we will have to possess our souls with patience until another appropriation can be had. In the mean time, much can be effected if the members of the profession will exercise their personal influence upon members of Congress in favour of liberal appropriations for the publication of this important work.

—

International Sanitary Conference.—The diplomatic sanitarians adjourned March 2d *sine die*. What they did is yet to be made public by the State Department; it is said that they did some good work, and held a number of dignified and protracted meetings. It will be interesting to see the result. If sanitation gets so mixed in an American Congress, what will it be in a Congress of diplomats? Diplomacy is not always healthy, and sanitary measures certainly must at times violate diplomacy to be effective.

—

National Board of Health.—Congress, after considerable discussion, during the last days of its session, appropriated $50,000 for the use of the National

Board of Health, but with the proviso that no other moneys heretofore appropriated and remaining unexpended should be made use of by the Board.

—

The Bad Odours of New York.—The committee of the N. Y. State Board of Health on effluvia and nuisances, has recently held meetings to inquire into the causes of the pestilential odours emanating from Hunter's Pt., Brooklyn.

At a meeting held Feb. 26, several bitter complaints were read from residents of Murray Hill and the adjoining fashionable quarters of New York. Dr. Chandler, President of the N. Y. Health Board, attributed the odours to the oil refineries, varnish, fertilizers, chemical, and ink factories, and to the sugar refineries. He believed such changes in the mode of manufacture could be introduced as would prevent the development of the bad odours.

At a subsequent meeting, held March 5, letters were read from a number of prominent physicians of the east side of the city complaining of the Hunter's Point nuisances. Residents of Brooklyn also testified to the offensive character of the odours. Dr. J. H. Raymond, Sanitary Superintendent of the Brooklyn Board of Health, said the Board would be glad to have the State Committee investigate nuisances, but that the Board would be capable as it was thoroughly desirous of effecting the necessary changes, if the laws defining its powers could be enforced.

—

Prosecution of Unregistered Practitioners in New York.—The New York County Medical Society has authorized its Censors to employ counsel for the purpose of prosecuting irregular and unregistered practitioners.

Medical Society of the State of New York.—The seventy-fifth annual meeting of this society was held at Albany, February 1, 2, and 3, Dr. William H. Bailey, President, in the chair. A large number of excellent papers were read.

The following resolutions were adopted.

"*Resolved*, that the Medical Society of the State of New York advises the various county medical societies that form its constituency, to endeavour to secure the coöperation of the other incorporated county and district medical societies, throughout the State, in the enforcement of the 'Act to regulate the licensing of physicians and surgeons,' passed May 29, 1880.

"*Resolved*, that, in the opinion of this Society, it is desirable for the legislature to thoroughly amend and revise the laws of this State in regard to the office and duties of coroners, and that the Society would recommend, for their consideration, the recent statute act adopted by the State of Massachusetts.

"*Resolved*, that a special committee of five be appointed, by the President, to be designated a 'Committee on the Code of Ethics,' whose duty it shall be to consider the question of desirable changes in the code, and who shall present to the Society, at the annual meeting in 1882, such suggestions on this subject as they may decide upon."

The President appointed, as this special committee, Drs. Wm. C. Wey, of Elmira, C. R. Agnew, of New York, S. O. Vanderpoel, of Albany, Wm. S. Ely, of Rochester, and H. G. Piffard, of New York. A resolution offered by direction of the New York County Medical Society, to the effect that the State Society investigate the propriety of making a change in the law preventing the disclosure in court of any information obtained by physicians in their professional character from their patients, was referred to the Committee on Legislation with instructions to report in 1882.

The following officers were elected for the ensuing year: President, Abram Jacobi, M.D., of New York; Vice President, Dr. William Goran, of Stony Point; Secretary, Dr. Wm. Manlius Smith, of Manlius. Drs. T. F. Cock, of New York, and Jos. C. Hutchison, of Brooklyn, were appointed delegates to the International Medical Congress to be held in London, in August. The society adjourned to meet at Albany on the first Tuesday in February, 1882.

—

Primary Cancer of the Pancreas.—Dr. KENNIG reports, in the *Petersburg Med Woch.* (February 5), a minute history of the case of this rare affection occurring in a woman aged fifty-three.

—

Gastric Remittent Fever.—In confirmation of the views respecting this disease advanced by Dr. F. Peyre Porcher in the January number of the *American Journal of the Medical Sciences*, we publish the following from Dr. D. I. CAM, of Asheville, N. C.:—

"The disease is essentially '*gastric.*' The bowels, if at all, are only slightly involved. It is an *irritation*, *not* an inflammation. This is the true pathological state. My study of this disease, which has been deep and extensive, does not lead me to agreement with the view expressed, or at least suggested, by Dr. Charles West, that it is the child's typhoid fever. There is one sign of the disease which I consider as nearly *pathognomonic*, so nearly invariable is it. This is the child lying with the eyes obstinately closed, only opening them when aroused by being shaken or loudly spoken to.

"As regards the treatment, I yet pursue substantially the course which you mention; but I now use bismuth and oxalate of cerium every three or four hours, considering these as among the best means we have of allaying gastro-intestinal irritation; and I use injections of warm water and assafœtida p. r. n. to move the bowels—not insisting upon *purgation* as an important part of the treatment. The mortality must be infinitesimally small. If I have ever lost a case, I cannot remember it.

"The disease is as common *here* as it is on the seaboard or elsewhere."

—

University of Pennsylvania. Installation of the Provost.—On the 22d of February, at the Academy of Music, in the presence of a large and imposing assemblage Dr. William Pepper was duly installed, by the Governor of Pennsyl-

vania, as Provost of the University. In his installation address Dr. Pepper considered the past progress and plans for the future of the University. In the evening a reception was given to the Provost by the Penn Club.

—

Vienna Medical Faculty.—Professor Czerny has been elected to fill the chair left vacant by Prof. Dumreicher, and Prof. Kaposi to succeed Prof. Hebra.

—

College of Physicians and Surgeons, Baltimore.—The faculty of this institution have decided to lengthen their curriculum to six months, and to obtain the doctorate a student must have read medicine under a preceptor for one year and have attended two six months' courses.

—

Value of the Dentaphone.—Mr. EDMUND TRIBEL, Superintendent of the Royal Asylum for the Deaf and Dumb in Berlin, has made a series of extensive and critical experiments with the dentaphone as an aid to hearing, with entirely negative results. He states (*Archives of Otology*, Dec. 1880) that where deaf-mutes are concerned, the dentaphone, in its present condition at least, cannot be put to any practical use, not even as a means of advancing articulation, and he believes that the instrument cannot give any noteworthy assistance to any one whose hearing is in the least defective. These results agree entirely with those obtained by competent observers in this country.

—

Health of New York.—The number of cases of contagious diseases reported to the New York Health Board, for Feb. 1881, are as follows:—

Smallpox	62
Scarlet fever	657
Diphtheria	402
Measles	169
Typhoid fever	23

Smallpox has somewhat increased during the last month. Eight cases were removed to the Riverside Hospital, Blackwell's Island, on March 10th, and seven cases were reported on March 11th. The officials of the Vaccinating Department of the New York Health Bureau are vaccinating large numbers in the tenement houses. The department vaccinated 48,000 persons in 1880. The virus employed is bovine, and comes from calves kept on a farm at Clifton, New Jersey.

The mortality of the present season is unusually large. On March 11th 122 deaths were reported, while the number for the corresponding week of previous years was below 100. Although the various contagious diseases, as well as pneumonia, prevail more extensively than is usual, the increased mortality can hardly be accounted for in that way. The computations of the Bureau of Vital Statistics rest upon the last census, while the present population of the city is believed to have been largely augmented by transient visitors, from West and South. The total mortality for the five weeks ending March 5th was 3520, and that for the five previous weeks 3540.

At a meeting of the New York Academy of Medicine, held March 17, 1881, Dr. A. L. Loomis called the attention of the Academy to the largely increased death-rate of the city. He said: "All of us have noted the increased malignity of diseases, both acute and chronic, recently, and we have been alarmed by the increase of the mortality rate in our city. Old diseases seem to have taken new forms of violence, and fevers of a new type have spread through the city, whose symptoms and development put them beyond our power of classification. Those

who have had patients advanced in years who are suffering from illness of this new nature have been forced into the greatest anxiety, for what before was little feared now proves dangerous. What is the cause? Have the diseases themselves taken a new direction, or is there some new danger among us that deserves to be discovered and removed?

"It is our duty to answer these questions if we can, and to answer them promptly. From my personal inquiry into the subject I am led to lay down the following four propositions:—

"*First.* That the city must now be considered as in a malarial condition.

"*Second.* That our sewerage system is very defective.

"*Third.* That large quantities of animal and vegetable matter are undergoing decomposition in our streets.

"*Fourth.* That nearly all diseases are now more malignant and fatal than they have been in my experience in the last twenty years.

"I believe that the factors I have named are responsible for the low condition of the public health; nor does it seem strange to me at all that there is such a high percentage of mortality in this city. I predict that, if the causes referred to are not removed, an epidemic of great proportions will certainly result."

Dr. Loomis then offered the following resolutions, which were seconded by Dr. Austin Flint, and unanimously adopted:—

"*Whereas*, it is our opinion that the uncleanly condition of the streets of this city is an efficient factor in increasing the malignity of many diseases, and thus contributes to the present alarming death-rate:

"*Resolved*, that, acting under a deep sense of our responsibility as members of a profession whose chief duty it is to check the development of disease, we earnestly warn the public against the danger of allowing this state of things to continue."

—

Anti-vivisection Bill.—Mr. Bergh has again presented to the New York Legislature the same anti-vivisection bill which he endeavoured to have passed a year ago. The Committee on Public Health, to which it was referred, have reported adversely to it.

—

Convalescents' Home.—This home, situated at No. 493 E. 118th St., New York, was organized last year with the object of providing a temporary retreat for convalescents recently discharged from the hospitals but still unable to resume their usual occupation. 47 patients were treated in it during the past year.

—

Health of Charleston, S. C.—Dr. F. PEYRE PORCHER, of Charleston, informs us, under date of March 18th, that a form of influenza prevails at present in that city and State. It is characterized by fever, catarrhal symptoms, cough, some pains in the head and limbs—sometimes by vomiting and redness of the tongue. He has noticed in two cases marked swelling and suffusion of the face. There is no eruption, and there is an absence generally of the severe pains and prostration which accompanied the Dengue of last summer. Sometimes the attacks are pretty severe, the fever being high, with some head symptoms, dizziness, etc. It has prevailed in Columbia and elsewhere, and we have heard of a number of cases on the Ashley River, ten miles from the city.

Scarlet fever exists to some extent in Charleston, and an occasional case of diphtheria, but the latter has almost completely disappeared. Though the children in the public schools are all being vaccinated, there is no smallpox.

Library of the College of Physicians of Philadelphia.—Dr. Frank Woodbury has been elected Librarian, vice Dr. Robert Bridges, resigned. The making of the Card Catalogue has been placed in charge of an assistant to the Librarian, and is now progressing satisfactorily.

—

Retrogression in Medical Education.—The Faculty of the Bellevue Hospital Medical College introduced, for the session of 1880–'81, important changes in the curriculum of instruction and in the requirements for graduation. The preliminary term was abolished, and the regular winter session was extended to six months. Attendance upon three winter sessions was made obligatory. Students were required during the two first years to attend all the lectures, didactic and clinical, and at the end of the first and second years to pass examinations in Chemistry, Anatomy, Physiology, Materia Medica, and Therapeutics. An examination in these branches having been passed, the third year was to be devoted to the practical departments of Medicine, Surgery, and Obstetrics. These changes were made by the Faculty with entire unanimity and with the expectation that a considerable pecuniary sacrifice would be demanded on the part of its members, who were actuated solely by a desire to secure a higher grade of professional acquirements for the graduates of the college.

In a circular just issued, the Faculty states that "The experience of the session of 1880–'81 has led them reluctantly to the conclusion, that to persist in the requirement of attendance during three courses will be to incur a risk, as regards the interests of the college, which they do not feel justified in assuming; and the purpose of this announcement is to state that, after the present session of 1880–'81, attendance during a third session will be optional and not obligatory. This college, like most American medical colleges, is self-sustaining; and the special provisions for instruction, which have been and will continue to be maintained, call for a large expenditure of money as well as of time and labour. With an undiminished desire to continue the requirement of the three sessions, and with not less willingness than heretofore to make whatever personal sacrifices may be necessary, the Faculty feel obliged, by a proper regard for the prosperity and usefulness of the college, to return to the requirements for graduation which were in force prior to the session of 1880–'81. In making the changes introduced during this session, it was foreseen that, a large proportion of the students in this college coming from distant parts of the United States, the necessary expenses of spending three winters in the city of New York would render difficult or impossible the attendance of many who would otherwise join the classes. Many students, of course, would be led to attend other colleges which require only two sessions for graduation. It was hoped, however, that the progressive movement of the Bellevue Hospital Medical College would secure approval and co-operation on the part of the medical profession sufficient to render the change feasible. In so far as a judgment can be formed from the present session, the profession is not prepared to sustain the movement.

"In announcing a return to their original requirements for graduation, the Faculty desire to state that all the new additions to the curriculum will be retained. It is not proposed to recede in the least from these. Students will have the same opportunities for practical exercise in the different departments as those enjoyed by the class of 1880–'81. For those who choose to attend during three sessions, the provisions as respects examinations in the elementary branches at the end of the second year, and an exclusive devotion to the practical departments during the third year, will be continued. To all students who are able to do so, now, as hitherto, attendance during three years is strongly recommended; and, from the number of those who have already matriculated with the expecta-

tion of attending three sessions, the Faculty entertained a belief that not an inconsiderable proportion of future classes will voluntarily follow their example."

—

Washington, D. C., Training School for Nurses.—This institution is now about completing its third session with a small but earnest class of nurses. It labours under many disadvantages in the want of funds and sufficient hospital accommodation for practical purposes, but has been recently encouraged by the interest which its active Board of Managers have succeeded in exciting among the residents of Washington, and which has resulted in an Art Loan Exhibition, the contributions to which are of a high order of merit—and which is conducted by a large number of those best able by their personal influence to insure success in the undertaking. The exhibition bids fair to prove a pecuniary gain, and a prize having been offered for the best essay on nursing, already 27 contestants have presented themselves.

—

A New Hospital for Washington.—A bill for the establishment of a general hospital that shall be independent of all private interests, or of sectarian influences, was accepted by the U. S. Senate Committee with a recommendation on their part to appropriate $125,000 for its benefit, but unfortunately was not put into proper shape until the last hours of Congress, and so died in travail. Its projectors, however, are sanguine of final success, and will be ready with their bill to push the matter at the opening of the next Congress.

—

Providence Hospital, Washington, D. C.—This hospital, which, up to the present time, has been for many years the only one possessed by the District, which could be made available for the general treatment of the better class of patients, is, it seems, controlled entirely by Sisters of Charity, the medical board occupying a very insignificant position in the exercise of its own authority in the treatment of disease, and none in the management of the hospital; holding their appointments at the will of the Sister-in-charge. As a natural consequence, a want of harmonious action on both sides resulted during the past winter in the enforced resignation of some, and voluntary resignation of others of the hospital staff, which fairly represented the best elements and interests of the local medical men, leaving but two men on the Board. A new staff was immediately organized which took their places—and, as a sop to Cerberus—one of the causes of complaint was removed, how effectually remains to be seen, by the appointment of a resident house physician; up to this time the rules of the Sisterhood would not permit one of the male sex to pass the night under their roof, unless he in some way required their care and attention. Sober young professional men with all their senses under control and prepared for emergencies, gave way to drunkards and debauchees.

—

International Medical Congress, London, 1881.—Arrangements for the approaching International Medical Congress are being energetically prosecuted by the Executive Committee. The Inaugural address will be delivered by Sir James Paget on the morning of August 3d. The following mornings will be devoted to the business of the various Sections; while the afternoons (with the exception of Saturday afternoon, which will be left free for garden parties, excursions, etc.) will be devoted to the general sessions of the Congress, at which four addresses will be given by four distinguished men of different nationalities, viz.: Prof. Huxley, on the "Connection of General Science and Medicine;" Prof. Volkmann, of Halle, on "Modern Surgery;" and Dr. John S. Billings, of Washing-

ton, on "Medical Literature;" the fourth address, to be given by a distinguished Frenchman, has not yet been definitely arranged.

The Executive Committee has announced the rules for the organization of the Congress, which "will be composed of medical men legally qualified to practise in their respective countries, who shall have inscribed their names on the Register of the Congress, and shall have taken out their tickets of admission. The subscription is fixed at one guinea, which amount is to be paid on inscription and before the commencement of attendance at the meetings. Each Member of the Congress will be entitled to a copy of the Transactions when published."

"Notices of papers, together with abstracts of the papers, to be read in any one of the sections must be sent to the Secretaries of that section before April 30, 1881. These abstracts will be regarded as strictly confidential communications, and will not be published until the meeting of the Congress. Any Member wishing to bring forward a subject not already on the programme must give notice of his intention to the Secretary-General at least twenty-one days before the opening of the Congress. The Officers of each Section will decide on the advisability of accepting any communication addressed to their Section, and also the time when it shall be made. No communication will be received which has been already published."

"No speaker is allowed more than ten minutes, with the exception of readers of papers and those who introduce debates, who may occupy fifteen."

The Reception Committee has decided upon giving an evening reception at South Kensington, and perhaps a second in the Albert Hall. The Lord Mayor of London purposes entertaining the members of the Congress at dinner at the Mansion House on August 4th.

—

Regulating the Sale of Proprietary Medicines.—We are informed that a bill has been drafted, which has received the official sanction of the New York Academy of Medicine and of the New York County Medical Society, and will be presented to the New York Legislature, requiring that the manufacture of proprietary medicines shall affix the formula of each nostrum to the bottle containing it, and designating a penalty to be inflicted for neglect of so doing.

—

A New Hospital for Brooklyn.—Mr. Geo. I. Seney has given $200,000 and land worth $70,000, at Seventh St. and Seventh Ave., Brooklyn, for the erection of a hospital constructed upon the cottage plan. A board of thirty-two trustees has been appointed who will superintend the erection of the new hospital.

—

Meetings of State Medical Societies will be held during the month of April as follows:—

Medical Society of Tennessee at Nashville, on Tuesday April 5th.

Mississippi State Medical Association at Winona, on Wednesday April 6th.

Medical Association of State of Alabama at Montgomery, on Tuesday April 12th.

South Carolina Medical Association at Newberry, on Tuesday April 19.

California State Medical Society at San Francisco, on Wednesday April 20th.

Medical Association of Georgia at Thomasville, on Wednesday April 20th.

—

A Medical Knight.—Queen Victoria has announced her intention of conferring the honour of knighthood upon JAMES RISDON BENNETT, M.D., President of the Royal College of Physicians of London.

Literary Notes.

Henry C. Lea's Son & Co. have in preparation a "Treatise on Midwifery," by Dr. Theophilus Parvin, of Indianapolis. It will be a copiously illustrated octavo volume of about 500 pages, and will be the first systematic work on obstetrics which has emanated from an American author since the publication of the late Professor Hodge's great work in 1864. Also a "Practical Treatise on Impotence, Sterility, and allied Disorders of the Male Sexual Organs," by Dr. Samuel W. Gross. Sterility is generally ascribed to the female, and she is apt to undergo treatment therefor without consideration as to the possible existence of the defect in the male, but Dr. Gross gleans from prominent specialists in female disorders that about one-third of the cases of sterility are due to the male, and that an examination of the causes of this condition should include the male as well as the female before operations are performed upon the latter.

The same house promises early in April a volume of "Lectures on Diseases of the Nervous System, especially in Women," by Dr. S. Weir Mitchell. The subject includes the wide scope of nervous disorders of the hysterical and their treatment. The book will be illustrated with five lithographic plates, showing the intimate connection of temperature, season, and climate, with attacks of chorea. Also a "Practical Treatise on Electricity and its Applications to Medicine," by Prof. Bartholow. The scope of the work embraces electro-physics and electro-physiology as well as electro-diagnosis and electro-therapeutics.

J. B. Lippincott & Co. have just issued the second volume of Prof. Hayes Agnew's "Surgery." It is, like the first, a profusely illustrated volume of 1066 pages. The third volume, which will complete the work, is in process of rapid preparation.

William Wood & Co. have issued in their "Library Series" a volume on the "Materia Medica and Therapeutics of the Skin," by Dr. H. G. Piffard of New York; and announce a volume on the Continued Fevers, by Dr. J. C. Wilson of Philadelphia.

D. Appleton & Co. have just published the long promised new edition of Prof. Van Buren's "Lectures upon Diseases of the Rectum;" the book has been greatly enlarged and indeed largely rewritten; and announce as in preparation "The Applied Anatomy of the Nervous System," by Dr. Ambrose L. Ranney, Adjunct Prof. of Anatomy in Univ. of City of New York. The work is intended to present the latest knowledge in the anatomy and physiology of the nervous system, and to show its application in medicine and surgery.

Dr. W. F. Mittendorf, Surgeon to the New York Eye and Ear Infirmary, has issued through G. P. Putnam's Sons "A Manual on Diseases of the Eye and Ear." It forms an octavo volume of nearly 450 pages, and is illustrated with some very handsome chromo-lithographs.

A German translation of the last edition of Dr. Hamilton's "Treatise on Fractures and Dislocations" is announced by Vandenhoeclk and Ruprecht, of Göttingen.

Index Medicus.—Mr. F. Leypoldt, of New York, the energetic publisher of the *Index Medicus*, undaunted by the pecuniary loss entailed by its two years of publication, but with firm faith in the ultimate support of the student members of the profession, announces his intention of continuing the publication for another year, in the hope that by the expiration of that time it may be placed upon a self-supporting basis, for which it requires only two hundred additional subscribers. The *Index Medicus* is a monthly classified record of the current medical literature (including contents of medical journals and transactions) of

the *world*, and is compiled under the supervision of Dr. John S. Billings, of the National Medical Library at Washington. It forms, in connection with the magnificent Index Catalogue of the National Medical Library, a complete index of medical literature to date, and is of inestimable value to every intelligent student, teacher, writer, and practitioner in the profession. We trust that the members of the profession will recognize the importance of insuring the continuance of the *Index* by at once forwarding subscriptions ($6 per annum) to Mr. Leypoldt, since upon the encouragement which he *now* derives depends his ability to continue its publication after this year. The worth of the work has been so fully recognized by all who use it that its suspension could only be looked upon as a great calamity.

—

OBITUARY RECORD.—Died, at Washington, on the 23d of February, aged 5 years, GEORGE ALEXANDER OTIS, M.D., Surgeon U. S. A. Dr. Otis, who is widely known as an eminent writer on military surgery, and as the compiler of the surgical volumes of the Medical and Surgical History of the War, was born at Boston, Mass., Nov. 12, 1830; he graduated in the Arts at Princeton College and in Medicine at the University of Pennsylvania, in 1850. He then visited Europe and prosecuted his studies in London and Paris, and returning to this country he entered upon the practice of his profession at Springfield, Mass. He entered the army as surgeon of the 27th Massachusetts Volunteers in September 1861, and after the close of the war he entered the medical corps of the regular army.

Surgeon General Barnes announces his death in the following official circular:—

"It is with profound regret and a sense of loss, not only to his corps, but to the medical profession, that the death of George Alexander Otis, Surgeon and Brevet-Lieutenant-Colonel U. S. Army, is announced to the Medical Corps of the Army. . . . .

"Surgeon Otis, with his personal observations of the surgical collections abroad, brought indefatigable industry and untiring energy to the development of the surgical and anatomical collections of the Army Medical Museum, which he has made the most valuable of their kind in the world. The compilation of the Surgical Volumes of the Medical and Surgical History of the War has placed Surgeon Otis confessedly among the most prominent contributors to surgical history.

"While on duty in this office Surgeon Otis wrote for publication no less than ten reports on subjects connected with military surgery, etc.; among which are his most valuable and exhaustive reports on 'Excision of the Head of the Femur for Gunshot Injury,' and on 'Amputation at the Hip-joint in Military Surgery.' Of great culture, retentive memory, and with a remarkable facility of expression he was, as a compiler and writer, conscientious in his analyses, giving his deductions from the facts before him with modesty, but decision. With such a record it is needless to speak of his zeal, his ambition, or his devotion to his profession and especially to the reputation of the corps of which he was so bright an ornament. While devoting himself to the preparation of the third and last surgical volume (now more than half completed) of the Medical and Surgical History of the War, he died in Washington February 23, 1881. His untimely death will be deeply deplored, not only by the Medical Corps of the Army, but by the whole medical profession at home and abroad."

—

To Readers and Correspondents.—The Editor will be happy to receive early intelligence of local events of general medical interest, or which it is desirable to bring to the notice of the profession. Local papers containing reports or news items should be marked.

DUNGLISON'S MEDICAL DICTIONARY—Just Issued.

EDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE: Containing a concise explanation of the various subjects and terms of Anatomy, Physiology, Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Medical Jurisprudence and Dentistry, Notices of Climate and of Mineral Waters; Formulæ for Officinal, Empirical and Di tetic Preparations; with the Accentuation and Etymology of the Terms, and the French and other Synonymes, so as to constitute a French as well as English Medical Lexicon. By ROBLEY DUNGLISON, M.D., late Prof. of Institutes of Medicine in Jefferson Medical College, Philadelphia. A new edition, thoroughly revised and very greatly modified and augmented. By RICHARD J. DUNGLISON, M.D. In one very large and handsome royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, $7 50; half Russia, $8.

bout the first book purchased by the medical stu- it is the Medical Dictionary. The lexicon ex- natory of technical terms is simply a *sine qua* . In a science so extensive, and with such aterals as medicine, it is as much a necessity to the practising physician. To meet the wants tudents and most physicians, the dictionary must condensed while comprehensive, and practical le perspicacious. It was because Dunglison's these indications that it became at once the dic- ary of general use wherever medicine was stud- in the English language. In no former revision have the alterations and additions been so great. More than six thousand new subjects and terms have been added. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference. We may safely confirm the hope ventured by the editor "that the work, which possesses for him a filial as well as an individual interest, will be found worthy a continuance of the position so long accorded to it as a standard authority."—*Cincinnati Clinic*, Jan. 10, 1874.

ASHHURST'S SURGERY—Now Ready.

E PRINCIPLES AND PRACTICE OF SURGERY. By JOHN ASHHURST, M.D., Professor of Clinical Surgery in the University of Pennsylvania, Surgeon to the Episcopal Hospital, Philadelphia. Second edition, enlarged and revised. In one very large and handsome octavo volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7 50.

ascientiousness and thoroughness are two very ked traits of character in the author of this book. of these traits largely has grown the success of mental fruit in the past, and the present offer is in no wise an exception to what has gone be- fore. The general arrangement of the volume is the same as in the first edition, but every part has been carefully revised, and much new matter added.—*Philada. Med. Times*, Feb. 1, 1879.

BRISTOWE'S PRACTICE OF MEDICINE—Now Ready.

TREATISE ON THE PRACTICE OF MEDICINE. By JOHN SYER BRISTOWE, M.D., F.R.C.P., Physician and Joint Lecturer on Medicine, St. Thomas's Hospital, etc. Second American edition, revised by the Author. Edited, with additions, by JAMES H. HUTCHINSON, M.D., Physician to the Pennsylvania Hospital. In one handsome octavo volume of nearly 1200 pages, with illustrations; cloth, $5 00; leather, $6 00; half Russia, $6 50.

e second edition of this excellent work, like the has received the benefit of Dr. Hutchinson's tations, by which the phases of disease which peculiar to this country are indicated, and thus eatise which was intended for British practi- rs and students is made more practically use- s this side of the water. We see no reason to ify the high opinion previously expressed with rd to Dr. Bristowe's work, except by adding ppreciation of the careful labors of the author in following the latest growth of medical science. The chapter on diseases of the skin and of the nervous system, with a new one on insanity compiled from the best sources outside of the authors' own long experience, and the valuable portion relating to general pathology, aid greatly in completing an exceptionally good book for purposes of reference and instruction.—*Boston Medical and Surgical Journal*, February, 1880.

BARNES ON DISEASES OF WOMEN—Now Ready.

LINICAL EXPOSITION OF THE MEDICAL AND SURGICAL DISEASES OF WOMEN. By ROBERT BARNES, M.D., F.R.C.P., Obstetric Physician to St. Thomas's Hospital, etc., London. Second American, from the second enlarged and revised English edition. In one handsome octavo volume of 784 pages, with 181 illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6.

. Barnes stands at the head of his profession in old country, and it requires but scant scrutiny a book to show that it has been sketched by a er It is plain, practical common sense; shows deep research without being pedantic; is emi- y calculated to inspire enthusiasm without in- ling rashness; points out the dangers to be avoided, as well as the success to be achieved in the various operations connected with this branch of medicine, and will do much to smooth the rugged path of the young gynæcologist and relieve the perplexity of the man of mature years.—*Canadian Journ. of Med. Science*, Nov. 1878.

CARPENTER'S PHYSIOLOGY—Just Issued.

PRINCIPLES OF HUMAN PHYSIOLOGY. By WILLIAM B. CARPENTER, M.D., F.R.S., F.G.S., F.L.S., Registrar to Univ. of London. Edited by HENRY POWER, M.B. Lond., F.R.C.S., Examiner in Natural Sciences, Univ. of Oxford. A new Am., from the eighth revised Eng. ed., with notes and additions, by FRANCIS G. SMITH, M.D., Prof of the Institutes of Med. in the Univ. of Penna., etc. In one very large and handsome octavo vol. of 1083 pages, with two plates and 373 engravings on wood. Cloth, $5 50; leather, $6 50; half Russia, $7.

e additions by the American editor give to the as it is a considerable value beyond that of the English edition. In conclusion, we can give our al recommendation to the work as it now appears. editors have, with their additions to the only work hysiology in our language that in the fullest sense e word is the production of a philosopher as well physiologist, brought it up as fully as could be ex- d, if not desired, to the standard of our knowl- of its subject at the present day.—*Journal of Nervous and Mental Disease*, April, 1877.

e merits of "Carpenter's Physiology" are so widely known and appreciated that we need only allude briefly to the fact that in the latest edition will be found a comprehensive embodiment of the results of recent physiological investigation. Care has been taken to preserve the practical character of the original work. In fact, the entire work has been brought up to date, and bears evidence of the amount of labor that has been bestowed upon it by its distinguished editor, Mr. Henry Power. The American editor has made the latest additions, in order fully to cover the time that has elapsed since the last English edition.—*N. Y. Med. Journ.*, Jan. 1877.

HENRY C. LEA'S SON & CO.—Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing its sixty-first year, the publishers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "THE MEDICAL NEWS AND ABSTRACT," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of FIVE DOLLARS *per annum*.

The "NEWS AND ABSTRACT" consists of sixty-four pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, contributed by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "MONTHLY ABSTRACT," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "NEWS AND ABSTRACT" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and
The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum),
} Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance,
} Five Dollars.
The MEDICAL NEWS AND ABSTRACT, invariably in advance, Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

THE

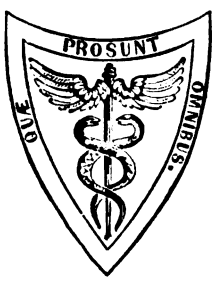
MEDICAL NEWS

AND

ABSTRACT.

EDITED BY

I. MINIS HAYS, A.M., M.D.



PHILADELPHIA:

HENRY C. LEA'S SON & CO

1881.

PUBLISHED MONTHLY AT $2.50 PER ANNUM IN ADVANCE.

Furnished in conjunction with the Quarterly American Journal of the Medical Sciences (in all nearly 2000 octavo pages) for $5.00 in advance.

ered according to the Act of Congress, in the year 1881, by HENRY C. LEA'S SON & Co., in the Office of the Librarian of Congress. All rights reserved.

MITCHELL ON NERVOUS DISEASES OF WOMEN—Just Ready.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, ESPECIALLY IN WOMEN. By S. Weir Mitchell, M.D., Physician to the Orthopædic Hospital and Infirmary for Diseases of the Nervous System. In one very handsome 12mo. volume of about 250 pages, with five lithographic plates. Cloth, $1 75.

The life-long devotion of the author to the subjects discussed in this volume has rendered it eminently proper that the results of his labors should be embodied for the benefit of those who may experience the difficulties connected with the treatment of this class of disease. Many of these lectures are fresh studies of hysterical affections; and others treat of the modifications his views have undergone in regard to certain forms of treatment, while, throughout the whole work, he has been careful to keep in view the practical lessons of his cases. The scope of the volume may be gathered from the following

CONDENSED SUMMARY OF CONTENTS.

Lecture I.—The Paralyses of Hysteria. II. Hysterical Motor Ataxia—Hysterical Paresis. III. Mimicry of Disease. IV. Mimicry of Disease. V. Unusual Forms of Spasmodic Affections in Women. VI. Tremor—Chronic Spasms. VII. Chorea of Childhood. VIII. Habit Chorea. IX. Disorders of Sleep in Nervous or Hysterical Persons. X. Vaso-Motor and Respiratory Disorders in the Nervous or Hysterical. XI Hysterical Aphonia. XII. Gastro-Intestinal Disorders of Hysteria. XIII. The Treatment of Nervous Exhaustion and Hysteria by Seclusion, Rest, Massage, Electricity and Full Feeding.

BARTHOLOW ON ELECTRICITY—Just Ready.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATIONS TO MEDICINE. By Roberts Bartholow, A.M., M.D., LL.D., Professor of Materia Medica and General Therapeutics in the Jefferson Medical College of Philadelphia. In one very handsome octavo volume of about 300 pages, with 96 illustrations.

EXTRACT FROM THE AUTHOR'S PREFACE.

"In my annual course of lectures on Materia Medica and Therapeutics, I have discussed more or less fully the subject of medical electricity as a therapeutical agent. It happened in this way that my attention was called to the need of a suitable text-book. That there are excellent works on medical electricity is undeniable, but some of them are too voluminous, others too scientific, and not a few wanting both in fulness and accuracy. I have attempted, in the preparation of this work, to avoid these errors; to prepare one so simple in statement that a student, without previous acquaintance with the subject, may readily master the essentials; so complete as to embrace the whole subject of medical electricity, and so condensed as to be contained in a moderate compass. I have endeavored to keep constantly in view the needs of the two classes for whom the work is prepared—students and practitioners. I have assumed an entire unacquaintance with the elements of the subject at the point of departure, for I am addressing those who have either failed to acquire this preliminary knowledge, or having acquired it, find that, after the lapse of years, it has become misty and confused.

In the account of electrical phenomena, I have adhered to the modes of expression with which the medical electrical text books have made us familiar.

This book, then, must be regarded as the exposition of electricity as a remedial agent, made by a medical practitioner for the use of other medical practitioners. No claim is made on the ground of pure science. It is believed, however, that the work makes an adequate presentation of the subject, regarding electricity as a remedial agent—as one of the means employed for the treatment and cure of disease."

GREEN'S PATHOLOGY—New Edition—Just Ready.

PATHOLOGY AND MORBID ANATOMY. By T. Henry Green, M.D., Lecturer on Pathology and Morbid Anatomy, at Charing Cross Medical School, London. Fourth American, from the Fifth enlarged and thoroughly revised English edition. In one very handsome octavo volume of 348 pages, with 138 fine engravings. Cloth, $2 25.

EXTRACT FROM AUTHOR'S PREFACE.

In preparing the fifth edition of my text-book on Pathology and Morbid Anatomy, I have again added much new matter, with the object of making the work a more complete guide for the student. All the chapters have been carefully revised, some alteration has been made in the arrangement of the work, and an addition has again been made to the number of wood-cuts. The new wood-cuts, as in previous editions, have been drawn by Mr. Collings from my own microscopical preparations.

SMITH ON CHILDREN—New Edition—Preparing.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. By J. Lewis Smith, M.D., Clinical Professor of the Diseases of Children in the Bellevue Hospital Medical College, New York. Fifth edition, thoroughly revised and rewritten. In one handsome octavo volume of about 800 pages, with illustrations.

HENRY C. LEA'S SON & CO.—Philadelphia.

CLINICS.

Clinical Lectures.

ON AMYLOID KIDNEY.

A CLINICAL LECTURE DELIVERED AT THE GOOD SAMARITAN HOSPITAL, CINCINNATI.

BY JAMES T. WHITTAKER, A.M., M.D.,

PROFESSOR OF THEORY AND PRACTICE OF MEDICINE IN THE MEDICAL COLLEGE OF OHIO.

GENTLEMEN: You may almost read in the face of this little girl that she has chronic disease of the kidneys. The partial paraplegia which you see still exists, shows that she has also some lesion of the spinal cord, and as nearly all such lesions at this age depend upon caries of the vertebræ, that is, upon Pott's disease, you will recognize that she is the victim also of bone tuberculosis. For although we shall have a clear history of an accident in this case, you are aware of the fact that trauma alone is not sufficient to explain or account for the vertebral caries without the previous presence of tubercle in the blood. What the trauma does is simply to determine the deposition or the localization of the tuberculosis. But we will leave this subject to the surgeons, and take up the complication which has presented itself in the course of her disease; a new catastrophe, so to speak, grave enough in its import, to divert to it our whole attention.

One of the internes, Dr. French, who has had immediate charge of the case will first read us the main outlines of its history.

"Mary K., æt. 15 years, native of Philadelphia, resided before admission to the hospital, on Front Street amidst bad hygienic surroundings.

The family history is indefinite and unimportant. No hereditary predisposition to disease can be traced, and her health has always been excellent previous to the accident which led to her present illness.

On Nov. 20, 1879, she fell through a hatchway from the second floor to the cellar of an apple-butter manufactory where she was employed and alighted in a sitting posture. When admitted to the house she suffered from complete paraplegia with retention of urine. During the first six weeks, the catheter had to be used regularly in the morning, in the evening, and at midnight. Then the vesical paralysis suddenly disappeared. At the same time she began to recover from the paraplegia and continued to improve so rapidly that on Jan. 1, 1880, she was able to stand.

About ten days after her admission, there was discovered a prominent knuckle-like protrusion in the lower dorsal region of the spine and a plaster-of-Paris jacket was applied. This treatment was continued until shortly before Christmas last, when the vertebræ seemed to have solidified, and she felt comfortable without artificial support. Strengthened as she was by the jackets, she was in a few weeks after the first application of them, able to walk. The motion of her limbs was carried on, however, wholly by the muscles of the gluteal region and thigh as the muscles of the leg and foot are still beyond her control. In order to maintain the equilibrium of her body, she has to partially flex her knees and she walks by giving her body a swinging motion from side to side and by dragging her feet with the toes turned outward.

The improvement of sensation in the paralyzed limbs has kept pace with the improvement of voluntary motion. Since the middle of last summer the sensation above the knees has been good, but below the knees, from two inches downward, the feeling is so obtunded that the prick of a pin could not be noticed, and the nail of a toe was removed without inflicting pain. At present the tactile sense is a little more acute as far down as the ankles. She has at no time had involuntary contractions of any of the affected muscles.

At various times during her illness, she has suffered from dysentery and diarrhœa; indeed her bowels could never be said to have acted properly. About the 15th of December last, signs of suppuration were noticed about the nail of the great toe of her left foot. On the 20th, the toe was more than twice its natural size, and a small quantity of pus was evacuated by incision. The discharge then continued several weeks until the second phalanx was removed. The foot became swollen and œdematous. About ten days later she complained of pains in her sides, in the lumbar region—sometimes darting upward. Then there was noticed a fulness of the face, the bridge of the nose seemed flattened, and her lower eyelids were puffed. Upon interrogation it was found that she had to micturate very frequently, passing very small quantities with great pain. Her skin now had a pallid hue, she became very anæmic, lost her appetite, and was easily nauseated. Auscultation and percussion revealed no lesion of the heart or lungs.

Examination of urine resulted as follows: sp. gr. 1.012; reaction neutral; colour, deep red; odour, strong; blood and albumen present in small quantities. The microscope showed red and white blood-corpuscles, small round epithelium cells and one or two granular casts.

From this time until the 15th, the patient's condition grew worse, both feet and legs becoming œdematous. Then a profuse diarrhœa set in which lasted three days, whereupon the dropsy rapidly subsided. Examination showed no change in the urine except a slight increase in the specific gravity.

During the last two weeks the only change worthy of mention has been the occurrence of obstinate and frequent vomiting.

Urinalysis to-day with the following result. Quantity in 24 hours, 20 ounces; specific gravity 1.010; colour dark red; odour strong; reaction neutral; albumen, less than 1 per cent.; blood, earthy phosphates, pus, colouring matter normal. Under the microscope are seen numerous white blood-corpuscles, round and pavement epithelium, pale hyaline casts, and an occasional granular cast. In fresh specimens red blood-corpuscles can be seen. Examining the small quantities as they are passed, the colour is found to vary from a very pale to a deep red, but it is never clear. The

amount of albumen varies also in different specimens from a mere trace to about one per cent."

I remarked to you, at the start, that you might read in the face of this little girl something of the nature of her disease. I had reference then to her almost unearthly pallor, and to the still evident puffiness of the face. If, now, you will simply recall the nature of the disease which preceded, and which probably produced the kidney affection, you will recognize also its form. The appearance of the patient, the history of the disease, above all, the condition of the urine, speak for amyloid degeneration of the kidneys.

Fatty degeneration we know very well as the commonest mode of the death of any cell. With calcareous degeneration we are as fully familiar in the coats of the larger arteries. Pathologists have made us familar with these tissue changes ever since morbid anatomy was especially studied. But amyloid degeneration is something new. Our definite knowledge of it dates from our own decade, and though we know of it already what it is, and when it appears, it must remain for another decade to inform us exactly why it occurs.

As might have been premised almost, our first knowledge of the amyloid process came from the study of the liver. The changes it produces in this organ are so gross, so palpable we might say, in life, as to have early attracted the attention of the pathological anatomists. So, some vague mention is made of it in the old writings of Stahl and Boerhaave, but their descriptions included all kinds of "Infarctions, Obstructions, and Engorgements" as they called them; conditions all supposed to be due to an accumulation of "altered, thickened, or corrupted blood within the bloodvessels."

Budd says of Laennec, who noticed everything, that he noticed also the "waxy" liver which he, however, considered to be a variety of fatty liver. The first mention of the condition with a distinct description was made by Antoine Portal, in 1813, who says that he "found the liver excessively voluminous, reduced to a substance like lard, both in colour and consistence, in the body of an old woman who had various exostoses and ulcerations about the genital organs." Nothing but unimportant and isolated observations, as by Budd, Andral, Graves, were then made in the history of amyloid degeneration, until 1842, when Rokitansky cleared up the field, so to speak, by showing that amyloid degeneration was a general process with local expression in different organs, and that it stood in close genetic relations to certain cachexiæ. Rokitansky was the first to describe amyloid degeneration of the kidney. Gairdner and Sanders next, 1854, demonstrated that the waxy condition of the liver and kidney also prevented in the spleen, while Virchow and Meckel almost at the same time, 1853, had already discovered the iodine and sulphuric acid reaction by which we are enabled to distinguish amyloid matter in any organ, at any time. This reaction, it was, by the way, which gave it its name. For starch is also coloured, as everybody knows, by free iodine. The coloration of amyloid matter is not blue like starch, but violet, deepening to mahogany. So Virchow called it matter like starch or amyloid. Meckel, however, was not willing to surrender the term "lardaceous," or, more strictly, "bacon-like" (speckartig). But Meckel fell into an error too, for he believed it due to the development of cholesterine. Now we know of amyloid matter, that it is neither starch nor fat, but is a pure albuminous principle, and for this knowledge we are indebted to Friedreich and Kekulé, 1860.

About ten days after her admission, there was discovered [illegible] knuckle-like protrusion in the lower dorsal region of [illegible] plaster-of-Paris jacket was applied. This treatment was [illegible] shortly before Christmas last, when the vertebræ seemed [illegible] fied, and she felt comfortable without artificial support. [illegible] she was by the jackets, she was in a few weeks after [illegible] of them, able to walk. The motion of her limbs [illegible] wholly by the muscles of the gluteal region and [illegible] the leg and foot are still beyond her control. [illegible] equilibrium of her body, she has to partially [illegible] by giving her body a swinging motion from [illegible] her feet with the toes turned outward.

The improvement of sensation in t[illegible] with the improvement of voluntary [illegible] summer the sensation above the kne[illegible] from two inches downward, the fe[illegible] pin could not be noticed, and th[illegible] flicting pain. At present the [illegible] down as the ankles. She has [illegible] any of the affected muscles.

[illegible]ATTACK OF AMYLOID KIDNEY.

[illegible]ally [illegible]al change, [illegible]. Thus (I quote [illegible]bserved two cases in [illegible]yloid change. Hirschfeld [illegible]ie mesenteric gland after a case [illegible]ases of amyloid degeneration in in- [illegible], Saemisch, and Leber amyloid degenera- [illegible]g hypertrophic exuberations similar to those [illegible]se of amyloid degeneration of a fibroid tumour of [illegible]ch states that he got the amyloid reaction from the [illegible]od clots; Jürgens had the same results in thrombi of [illegible]m; Virchow from the intervertebral, tracheal, and sym- [illegible]ulages of old people; and, lastly, Zeigler describes—and these [illegible]es of the greatest interest—amyloid tumours of the tongue and [illegible]s that had developed in the immediate vicinity of old gummata which [illegible] run their course.

All these facts speak strongly in favour of a local change in the affected part; just such change as regards localization, as is seen in the rule in the transformations into fat and salts of lime, the so-called fatty and calcare- ous degenerations.

But, however the change is effected, the alterations it produces in time in the organ affected are sufficiently gross and coarse for ready recogni- tion. We say in general terms that amyloid matter has four distinguish- ing characteristics, viz., a peculiar consistence (like dough or caoutchouc), a waxy lustre, a vitreous translucency, and a lack of colour But neither the macroscopic nor microscopic appearances enable us to pronounce upon it without fear of error. The true test of amyloid matter is its reaction with iodine and sulphuric acid. The surface to be tested must be first washed free of blood, else a mistake is very easy, and then painted over with a brush dipped in an aqueous solution of free iodine. In a few minutes the amyloid matter is coloured violet or brownish-red, like the colour of ma- hogany. On the super-addition of sulphuric acid the mahogany colour

our case bears upon the etiology of the
essary to more than state here that amyloid
ere are exceptions enough to make it a rule and
y affection. It follows, in the rule, close upon the
isease attended with persistent suppuration. Dickinson,
proposed a very pretty theory to account for it, based upon
Pus is alkaline, as we know, he said, and the long drain of pus
alkalizes the blood, and dealkalized fibrin is amyloid matter. The scientific treatment of the condition, therefore, is the administration of the alkalies. Unfortunately for this beautiful theory, there are typical cases of amyloid degeneration unattended by suppuration. Now, although there is no evidence of tuberculosis elsewhere, in this case, I take it for granted that the vertebral caries present is an indication of that disease.

Tuberculosis is the most prolific cause of amyloid degeneration. Wagner gives the percentage of cases at 56.25, Weber at 40.55, Hoff at 67.5; but aside from this question altogether, the bone caries present in the big toe is enough to account for it in this case. Bone caries is followed by amyloid degeneration, according to Wagner, in 23 per cent. of cases, according to Weber in 38 per cent., while Hoffman admits it as a cause in 7.5 per cent. of cases.

The next points in the history of this case bear upon the affection of the kidneys.

I have already tried to impress it upon you as a good routine system in the investigation of the symptomatology of disease of the kidneys to take up the study of them as offered first by the dropsy, second by the condition of the urine, and third by the nervous system.

There is no great amount of dropsy in this case, and that is the rule in amyloid kidneys. What there is, in the rule, shows itself in the lower extremities rather than in the face, as in our case, and is due not so much to the kidney affection as to the general hydræmia of a cachexia. Indeed, we might say this of all the symptoms offered by amyloid degeneration of any organ of the body. As Bartels puts it, "the issue of the forms of

disease attended by amyloid degeneration of the kidneys depends much more upon the fundamental malady, and the simultaneous affection of other organs than it does upon the renal disease itself." Many cases of amyloid kidney show no dropsy from beginning to end. Grainger Stewart saw general dropsy only six times in one hundred cases. Œdema of the legs and ascites characterize the dropsy of amyloid kidneys; neither dependent upon obstruction in the kidneys so much as upon the general hydræmia, and portal obstruction from simultaneous affection of the liver. So, the obstinate diarrhœa and vomiting which occur in advanced cases of amyloid kidneys depend for the most part upon the block in the portal circulation, or upon amyloid degeneration of the walls of the alimentary canal. I have often seen this child start up suddenly from a sound sleep and forcibly eject from the stomach all its contents, and then quietly fall asleep again.

The quantity of urine is reduced more than one-half in our case, which is the exception and not the rule. For, in the rule, the quantity is increased above the normal, though never to the degree so characteristic of renal cirrhosis. I have often had patients with renal cirrhosis point triumphantly to a large vessel brimful of clear, limpid, urine, the accumulation of a single night, as an indication of the supposed healthy action of the kidneys. A quantity to be proud of is seldom passed from amyloid kidneys, though enough escapes to prevent the block and side outlet into the immense reservoir under the skin, as in chronic parenchymatous nephritis.

A small amount of albumen is present here, which is in accord with the rule, a few clear casts and white corpuscles, a like conformity, but also some red blood-corpuscles which is a decided exception. But we have to say of amyloid kidneys always, that this form of kidney disease is so often complicated by the others as to present the greatest variations in every respect of them all. Our endeavour is rather to ascertain which form predominates, than exclusively prevails.

Symptoms on the part of the nervous system, so frequent in the acute and chronic parenchymatous forms, as well as in renal cirrhosis, are distinguished by their absence in amyloid kidneys. Beyond a recent tendency to sopor, this child has shown no signs of uræmia at all. Bartels says that he knew but one case of amyloid kidneys to die of apoplexy. So this element of sudden danger is lacking in this form of Bright's disease.

The prognosis in all cases of amyloid disease is bad. It is most favourable, I need hardly say, when dependent upon syphilis, because for syphilis we have means of relief. Prevention is the greatest victory and this we may secure, at times, by free evacuation of pus, and destruction, or obliteration of pus-secreting surfaces. Amputations, resections, drainage, aspirations, these are the prophylaxes of amyloid disease. The treatment of syphilis continued long after the subsidence of manifest signs, the thorough neutralization of chronic malarial poisoning, resort to change of climate in phthisis pulmonalis, prevent the development of many a case of amyloid disease. So far as concerns drugs, from the standpoint of existing knowledge, there is but one worthy of trial in amyloid degeneration, and that is iodine. Whether its worth here depends upon its efficacy in syphilis and scrofula, the so frequent forerunners of the condition, is a question yet *sub judice*. We will push it with this child in the form of the syrup of the iodide of iron. From small doses of mor-

phia in cherry laurel water frequently repeated, we have had the best results in combating the vomiting which was the most distressing and exhausting feature of this case. Moreover, we will ask the surgeons to cut out the carious bone at the toe, not in the hope of removal of the amyloid matter, which has already substituted structure in the kidneys and the spleen, the enlargement of which I readily detect, but of faintly helping (perhaps we ought to say, making a feint of helping), to prevent the continuance of the change. Every hope is in prophylaxis. Pitiful is the therapy of amyloid disease when at all advanced. The patient is already reduced by the disease which brought it on. Then it steals upon a prostrate victim like the jackals which prey upon the wounded on the field of battle.

REMARKS ON THE DIAGNOSIS AND TREATMENT OF PRURITUS VULVÆ.

A Clinical Lecture delivered at St. Mary's Hospital.

By ALFRED WILTSHIRE, M.D., F.R.C.P.,
Joint-Lecturer on Obstetric Medicine at the Hospital.

Gentlemen: The patient, an elderly woman, who is now before you, has brought this specimen of her urine at my request; our object in procuring it being the demonstration to you that it contains sugar. Its specific gravity is high—1040; and, on applying Fehling's test, with heat, you may observe that a copious precipitate of suboxide of copper is thrown down. We conclude, therefore, that it contains sugar—the influence of any other reducing agent, *e. g.*, uric acid, being excluded.

Looking at the patient, probably a few of you would suspect that she is diabetic: she is neither notably thin, nor has she had, until recently, either thirst or a large appetite; moreover, the amount of urine voided when she first attended was not remarkable; now it averages seven or eight pints in the twenty-four hours. We were led to suspect the presence of sugar in the urine from her complaint of itching of the private parts, the symptom for which she sought relief; and at each visit we have found it to be loaded with sugar. The vulvar itching was at once greatly relieved by a borax lotion; and although there is no abatement of the glycosuria, yet the itching has scarcely troubled her again; in fact, she now makes no complaint of it.

I have availed myself of this case as illustrating an important form of pruritus vulvæ due to a general disease of great gravity, the first clue to which is sometimes obtainable through the symptom of vulvar itching long before the manifestations of diabetes commonly regarded as classical—*e. g.*, wasting, thirst, voracious appetite, polyuria, etc.—have declared themselves. This symptom of pudendal itching—for males, though in a less degree, are subject to it—has repeatedly led me to the discovery of glycosuria. Observe that I use the word glycosuria rather than diabetes; for not all the patients whose urine contains sugar are diabetics, that is, they do not all have an excessive flow of urine, polyuria being manifested later, if at all. Clinically, it is important to recognize that glycosuria occurs in stout as well as in thin folk; otherwise, the malady may be long overlooked. The symptom of pudendal itching will direct your attention to the state of the urine, and may thus lead to the early detection of sugar. Before dismissing the patient, I will ask you to observe her teeth, and note the injection of the capillaries of her cheeks. Her teeth are being shed without decay, as the teeth

of elderly diabetics sometimes are, apparently from shrinking of the sockets, the alveolar processes wasting. In some cases, the teeth become brittle and crumbly. The tendency to injection of the facial vessels seems to be part of a general proclivity to capillary erethism, for flushing of other regions of her skin is easily excited. Here is a photograph of another patient who was tormented with vulvular pruritus, a stout gouty diabetic; and, as the local condition in her case was typical, I will describe it.

The separated vulva looked pale, rough, granular, thickened, and sodden—in texture like the rind of a Seville orange, only dead white. Mark the absence of pigment: it is diminished or absent in many cases, just as in pruritus ani. This change I regard as neurosal. Very rarely there is increased pigmentation, a slaty hue overspreading the parts; or there may be suffused dusky redness, or a glazy redness, especially in the aged, mostly arising from acrid uterine discharges.

But the glycosuric or diabetic is only one of many forms of pruritus vulvæ; and, as the symptoms may arise from a variety of causes, we must review these together, in order that you may acquire a comprehensive knowledge of them. Broadly, they may be divided into two chief classes: the *local* and the *general;* but in some instances these overlap.

Local Causes.—These are as follows:—

a. Animal and vegetable parasites may infest the vulva, and excite itching. Among the former are pediculi, acari, and ascarides. Pediculi and ascarides are easily recognized, but the itch-insect may be overlooked. Ascarides are more common in girls than in women, but are by no means unfrequent in the latter. They crawl from the anus over the vulva, and thus annoy; sometimes provoking leucorrhœa also. (The same may be said of tænia, joints of tapeworm escaping *per anum* and exciting irritation in the adjacent parts; but this very rarely happens.) The vegetable parasites are of interest; for the itching appears in many cases immediately to depend upon the presence of certain low varieties, not only in the glycosuric cases, but also, it appears to me, in other instances, in which loss of pigment points to neurosal impairment. The *oidium albicans* (the thrush-fungus) has been met with, and also other low forms of vegetable life, as Friedreich, Hausmann, and others have observed. Sugary urine obviously supplies a most favourable pabulum for the development of lowly organized fungi. It is interesting in this connection to note that most of the successful remedies are parasiticides, as we shall see when discussing treatment. Parts whose innervation are impaired afford, as you are aware, a favourable nidus for the development of low forms of parasitic life, both animal and vegetable; and the flourishing of such organisms in the parts in question may be regarded as evidence of neurosal impairment, indicated, furthermore, by the occasional presence of leucoderma.

Among local causes, we have, further, several important affections, *e. g.*—

b. Diseases of the vulva (as vulvitis, abscess, carcinoma, oozing tumour, lupus, elephantiasis, etc.);

c. Diseases of the urinary system (urethra, bladder, and kidneys);

d. Vaginitis—gonorrhœal and other.

e. Diseases of the uterus (metritis, endometritis, senile catarrh, cancer, fibroids, polypi; acrid discharges arising from some of the foregoing, or occurring mainly in association with menstruation);

f. Ovarian and other tumours, and pelvic effusions;

g. Skin-affections—eczema, ecthyma, herpes, urticaria, acne, etc.

As regards the latter, eczema may be associated with diabetes, producing terrible suffering; while urticaria suggests ovarian disease. Ecthymatous spots, with ashen-gray bases, may indicate grave cachexy (? syphilitic); while the herpetic vesicles are prone to crop out periodically in females of gouty parentage just be-

fore each menstrual period. The French attribute this to the herpetic diathesis. A pustular form of acne is sometimes accompanied by troublesome itching.

It is perhaps true, as a broad generalization, that syphilitic eruptions are not prone to itch; but I have met with marked exceptions to this in some syphilitic affections of the vulva, as in the patient of whom I show you a photograph illustrating elephantiasis of the clitoris and vulva, from whom I removed an hypertrophied clitoris weighing a pound and a quarter. Venereal warts may excite itching.

Malignant disease of the uterus and upper part of the vagina may provoke itching in two ways: first by acrid discharges; and, secondly, reflexly—the latter uncommonly. The same may be said of fibroids, polypi, sarcomata, etc. I have known pruritus to exist for a long time apparently as a consequence of pelvic effusions—*e. g.*, hæmatocele, cellulitis, partly perhaps from venous obstruction, and partly from implication of nervous structures. Some discharges from the interior of the womb are virulently acrid, and excite excoriation of the parts over which they flow. These are revealed by the speculum.

Urethral and vesical affections—*e. g.*, vascular growths, stone, incontinence, etc.—are sometimes complicated by vulvar itching. Careful local investigation, therefore, is obviously necessary in all such instances; and even when the predisposing cause is general, as in diabetes, the local condition may be significant and important, yielding, as has already been pointed out, valuable information.

General Causes.—Among the general causes of pruritus vulvæ, we find: (*a*) diabetes (glycosuria), (*b*) pregnancy, (*c*) gout (or lithiasis), (*d*) syphilis, (*e*) prurigo senilis, and perhaps (*f*) the dartrous diathesis of the French. (Diphtheria must be mentioned as an extremely rare cause.)

a. The patient whom you have seen is now a type of the diabetic causes. Such are not uncommon; but they usually escape detection until other symptoms obtrude themselves. I have shown you and met with many such; although usually among the middle-aged or elderly, yet also in patients under twenty, as in the case of a young woman who was under my care some years ago. She consulted me for severe pruritus vulvæ; and, on examination, I found extensive eczema. I at once examined her urine, and found sugar. She had then no other symptom indicative of diabetes, nor did she present any for many months; but she ultimately died of it; and I belive her brain is figured in Dr. Dickinson's able work on diabetes. We have had other cases here, as you know, notably one in which diabetes came on rapidly after severe mental trouble; the vulvar pruritus alone leading to its detection.

b. Pregnant women are liable to a severe form of pruritus vulvæ. It is usually accompanied by an irritating discharge—whitish, creamy, or yellow in colour, and occasionally very abundant. Sometimes aphthæ and erosions are seen upon the turgid labia or cervix, or there may be vaginitis granulosa. Most of the cases that I have seen have been accompanied by extreme venous turgescence. The distress experienced by some sufferers appears to be painfully augmented by the exalted nervous tension attending pregnancy. Parturient women seldom make complaint of pruritus; but I have seen a few instances in which it occurred, and it has been associated with hydroa or herpes gestationis.

c. The gouty form is not uncommon, but, fortunately, it is seldom intense or obstinate unless complicated with glycosuria. It may be seen in plethoric women, even when young, recurring before menstruation, when the urine is apt to be loaded with lithates. Sedentary habits, beer, and strong wines, aggravate it. Stout gouty women at the change of life are prone to suffer from vulvar irritation; some, doubtless, are examples of gouty glycosuria, in whom climacteric disturbance intensifies the mischief. Ordinarily indulgence in the pleasures of the

table provokes itching, while abstinence alleviates. Obese elderly women are liable to vulvar irritation, the secretions of the parts apparently possessing very irritating properties; but you will be amply repaid for your trouble by systematically examining their urine for sugar, for thus you may be enabled to detect latent diabetes.

d. As regards syphilis, it is seldom that the early or acuter manifestations of the disease excite itching. It is associated rather with later phenomena, as in the case of elephantiasis already mentioned; but chancres and venereal warts may provoke much irritation.

e. Sometimes intractable pruritus vulvæ appears to be part of a general affection, the so-called prurigo senilis, and is associated with general cutaneous hyperæsthesia. Klob says that there are little elevations of the skin, like goose-flesh, consisting of growths analogous to tubercular formations, and giving rise to violent itching. These cases are grave. Some are amenable to the bromides, which are advocated by Gueneau de Mussy, in the form of lotion or ointment, as well as internally. Arsenic and cod-liver oil are also indicated. Such cases are not to be confounded with senile pruritus arising, as commonly happens, from phtheiriasis.

f. A tendency to pudendal itching seems to prevail in those who have what the French call the dartrous diathesis. In them, fissuring of the affected parts is often observed, the skin presenting a glazy, cracked appearance. Renal disorder, notably oxaluria and inadequacy, may be associated with this condition.

All forms of pruritus vulvæ are subject to periodical exacerbation. Some patients suffer only at night, after becoming warm in bed, experiencing comparative freedom during the day. All who menstruate are conscious of aggravation at that time. Stimulants, as a rule, exert an injurious effect. Sedentary occupations aggravate pruritus: governesses and seamstresses, for instance, suffering much, as also do those who work treadle sewing-machines. Piles and hepatic disorders generally are conspicuous.

Treatment.—While in many cases vulvar itching readily yields to treatment, in others it proves obstinate and intractable, taxing our therapeutical resources to the utmost. Here, as in other affections, a clear diagnosis as regards causation is generally essential for successful treatment. It is obvious that a symptom owning so many and varied causes cannot be appropriately treated in a routine manner; search must made into the origin of each case, and treatment based upon the knowledge thus acquired.

Attention to cleanliness will often do much to allay irritation, and should always be enjoined. Demulcent washes are preferable to soap, unless carbolic or coal-tar soap be used, and usually even these are inadmissible. Almond-meal, strong bran-water, decoction of rice, marsh-mallow, slippery elm, or fine oatmeal, are suitable, especially the first, which, if pure, yields during use a marked odour of hydrocyanic acid, and appears to soothe materially.[1] The prohibition of friction may be required, some afflicted sufferers finding transient relief only during scratching, which may be indulged in to an extent involving serious consequences. Relief may be so frequently sought in this manner, as to exclude sufferers from society, and even from the family circle; while other regretable results, moral as well as physical, may ensue.

When pruritus is due to acari or pediculi, ointment of sulphur, white precipitate, or stavesacre speedily cures, by destroying the insects and their ova. If nits persist about the pubic hairs, a lotion containing bichloride of mercury and acetic acid will dissolve them. Ascarides are destroyed by a carbolic lotion (1 in 60);

[1] Experiment has proved that hydrocyanic acid is evolved.

but general, rather than local, treatment should be relied on for their eradication —iron, quinine, cod-liver oil, together with enemata of hamamelis, lime-water, iron, etc.

The vegetable parasites are very efficiently treated by unirritating parasiticides, *e. g.*, borax, boracic acid, sulphurous acid, etc. Here I would again emphasize the fact that most of the favourite remedies for vulvar pruritus are parasiticides. It suggests that—whether from the sugary pabulum provided by diabetic urine, or from alteration in the nutrition of the parts from neurosal impairment, or from a combination of the two, when coincident—the immediate exciting cause of pruritus is, in numerous instances, the growth upon the implicated parts of low forms of vegatable growth.

Friedreich (Virchow's *Archiv*, Band 30, p. 476) alleges that the pruritus is due to the development of fungous organisms, and my own observations are certainly confirmatory of this view. It is a curious clinical fact, that patients are often freed for days from itching by a single application of a parasiticide; I have observed this repeatedly in glycosuric cases, after the use of a strong borax lotion. It is best to use such remedies in a fluid form, for, when necessary, powerful combinations may thus be made in the unhappily intractable cases. In my experience, fatty preparations of drugs do not suit so well for local application as non-fatty; and yet great relief may be afforded by some ointments, as we shall see presently.

Many cases of pruritus vulvæ are promptly relieved by a borax lotion, and it is well to use this simple and efficacious remedy where not contra-indicated. A drachm to five ounces of warm water is a good standard strength, but a stronger solution is usually needed, seldom a weaker. Hydrocyanic acid may be added —say ℥j of the dilute acid to ℥x, or morphia (gr. ij), atropia (gr. ½), aconitia (gr. ½), or veratria (gr. ½). Infusion of tobacco (half an ounce to the pint) alone relieves some cases, and forms a good vehicle for borax or boracic acid. It is not well to use glycerine with the borax as a rule, as it is apt, owing to its affinity for water, to aggravate the irritation. Some find relief from chloral lotions, but the drug has not always suited. Strong decoction of poppy is a soothing vehicle for borax, etc. Ice alone will relieve some; while others can get relief only from the use of very hot water. In excessively severe cases, the ether-spray might be tried.

Boracic acid is an excellent remedy; but, being much less soluble in water than borax, is not so handy as a lotion. It may be combined with hydrocyanic acid, morphia, atropia, aconitia, veratria, etc. In the form of ointment, where fats do not disagree, it often soothes greatly. A non-rancid fat should alone be employed as the vehicle, *e. g.*, freshly made spermaceti cerate, vaseline, fossiline, or purified benzoated lard, etc.

Lotions of iodine occasionally answer, *e. g.*, two drachms of iodine in ten ounces of elder-flower water. Electricity may afford relief in neurosal cases. Probably faradism would be the preferable form.

In simple vulvitis, lead, borax, or carbolic lotions relieve. An ointment of calomel or bismuth is also good. Malignant affection of the parts call for appropriate treatment, such as ablation, where practicable; but sedative applications (conium, opium, belladonna) alone are often all that we can employ.

Urethral caruncles should be removed; and urethritis, gonorrhœal or other, treated *in loco*. Cystitis, stone, and kindred vesical affections and renal diseases, must be treated according to their several indications. Success is unattainable if they be overlooked. Vaginitis, gonorrhœal or otherwise, demands thorough treatment. The packing of the upper part of the vagina with a tampon soaked in glycerine, with carbolic acid, lead, tannin, chloride of zinc, or borax, seems

the most prompt method of cure; but injections of these agents may suffice, and may be preferable. When the itching is associated with chronic metritis, iodized tampons are useful; and so are copious irrigations of the parts with warm water.

When vulvar irritation arises from acrid discharges proceeding from the uterine cervix or cavity, the use of a tampon filling the top of the vagina is most efficient. Cotton-wool, iodized or carbolized, answers well. As glycerine is apt to excite a watery flux, it is not always admissible, but may now and then be required. Absorbent wool, dusted with iodoform, boracic acid, morphia, tannin, camphor, chloral, and such like, may be packed against the cervix uteri, so as to arrest and disinfect virulent discharges; the choice of drug being guided by the form of disease present. It is necessary to attach a string to each tampon to facilitate its withdrawal. Vaginal and pudendal pruritus, arising from acrid uterine discharge, is mostly seen in elderly women, and may be accompanied merely by glazy redness around the ostium vaginæ. Search for uterine discharge may, therefore, be necessary. I have seen it in cancer of the fundus uteri, as well as in senile catarrh.

Local treatment by the tampon may be demanded in malignant disease of the uterus, and also in fibroids and polypi when accompanied by irritating discharge, *e. g.*, in disintegrating calcified growths. Removal of the diseased structures is preferable where practicable; and the same may be said of cases dependent upon ovarian growths. Urticarious itching is the form of pudendal irritation mostly seen in association with ovarian tumours. A lotion of bicarbonate of soda, or one of borax with hydrocyanic acid, generally relieves. Magnesia internally is useful. When there is previous turgescence of the vessels of the part, as may be seen from stasis in some pelvic effusions, relief is afforded by the watery flux provoked by the presence of a well-soaked glycerine tampon; and a mercurial and saline purge is helpful when portal congestion is present. Eczema—often symptomatic of glycosuria, remember—may be very obstinate. Dusting freely with fine oxide of zinc answers well when ichorous weeping is abundant. If fissure be present, a poultice formed of the clot resulting from the addition of two drachms of liquor plumbi to ten ounces of new milk is most useful. Sometimes calomel ointment will alone relieve, as in certain instances of anal mischief; or bismuth may answer, dry or otherwise. Mercurial ointment suits certain cases excellently.

Angry ecthymatous spots appear to yield only to calomel, either dry, or in the form of ointment or of black wash. Opium is a valuable adjunct, both internally as well as externally.

Herpetic eruptions are benefited by a small mercurial dose followed by a saline purge, as the effervescent sulphate of soda, and the local use of borax lotion. If they be very severe, hydrocyanic acid and other local sedatives may be necessary; but it must be borne in mind that these herpetic manifestations generally run a definite course, the vesicles dying away completely. They are often accompanied by lithiasis, and may excite preputial herpes in the male.

It is unnecessary for me to dilate further on the importance of recognizing diabetes as a cause of pruritus vulvæ. When the parent disease is discovered, those restraints upon diet, drink, etc., which observation and experience have taught us to be necessary, should be strictly enjoined. Unhappily, we have no cure for confirmed diabetes, but much may be done by judicious treatment and management, alike for those who are threatened with glycosuria, as for advanced cases. Immense comfort may be secured by the habitual use of cleansing ablutions, and of borax or boracic acid.

Gouty diabetics may experience much benefit from a course of the Bath waters and baths, or from those of Carlsbad, as I have seen there; but I doubt whether confirmed and advanced diabetics are so relieved. The insomnia of diabetic pru-

ritus vulvæ sometimes shows a gratifying amenability to codeia, in the form of one-grain doses in pill. The bromides are also useful as hypnotics.

The distress that pregnant women sometimes experience, especially towards the latter months, may be terrible. When associated with aphthous ulceration, and the oidium albicans is present, nothing relieves more quickly than a lotion of sulphurous acid. Some prefer the hyposulphites, and in either case prolonged use is undesirable. As sulphurous acid is very volatile, it is best to mix a tablespoonful of the pharmacopœial solution with half a pint of warm water, barley water, or almond emulsion, freshly for each occasion. Another very useful lotion is formed by two drachms of bicarbonate of potash in half a pint of water. This should also be injected into the vagina; it checks the discharge, often alkaline, which seems to excite irritation. Borax is again a valuable agent, and so is lead.

In some cases, relief is only obtained after treating the cervix uteri; as when aphthous ulceration is seen around the os. Nitrate of silver, lightly used, suffices. Bromide of ammonium internally is highly serviceable. Attention should be paid to the state of the bowels, and to the hepatic and renal secretions, for in many cases elimination is defective. Turkish or hot-air baths exert a better effect over some of these cases than any ordinary treatment; and the same remark applies to certain other varieties of pruritus vulvæ, *e. g.*, those seen in the obese, gouty, and (senile) pruriginous. Jaborandi may prove very helpful under similar circumstances, by producing profuse diaphoresis. Diuretics—juniper, broom, potash, lithia, etc.—are often beneficial, as in gouty cases, especially when combined with colchicum. Restrictions as regards meat, beer, and wine, should be imposed on the subjects of lithiasis.

When vulvar pruritus appears to be part of a general prurigo senilis, besides the local applications already indicated, a lotion of bromide of potassium may afford ease, as has been shown by Dr. Gueneau de Mussy. The same drug given internally is helpful, the affection appearing to be part of a general nervous erethism. Arsenic exerts a controlling effect in some instances of senile prurigo, as well as in those due, as the French allege, to the dartrous diathesis.

Arsenic may be said to be indicated in the neurosal forms, and especially when there is marked loss of flesh. It has appeared to me to benefit most those who are the subjects of leucoderma.

It remains only to remark that, in the intractable cases, frequent changes of remedies may be inevitable for the relief of torment. Chloroform locally applied answers occasionally; it may be used in the form of vapour, liniment, ointment, or lotion. Bichloride of mercury, also a parasiticide, gives relief to some in the form of a lotion, but it requires caution in its use. Used in the proportion of gr. j to gr. v to ℥viij of mistura amygdalæ, it may afford great relief.

I have no experience of section of the pudic nerve in inveterate cases, nor am I aware that it has ever been practised; but Sir J. Simpson mentions that he once severed the skin from the subjacent structures, with considerable benefit.—*British Medical Journal*, March 5, 1881.

Hospital Notes.

BELLEVUE HOSPITAL, NEW YORK.

(Service of Dr. AUSTIN FLINT, Sr.)

Quebracho in Dyspnœa.

(Specially reported for the MEDICAL NEWS AND ABSTRACT.)

CASE 1. *Aneurism of the Ascending Arch of the Aorta; Cardiac Hypertrophy. Great Dyspnœa. Treatment with Fluid Extract of Quebracho.*—Henry J., æt. 43, U. S., wood-carver; admitted December 8, 1880. The patient has

not, habitually, indulged in alcoholics. In 1870, he had primary syphilis, for which he was treated. Secondary or tertiary symptoms never appeared. In 1872, he became affected, without apparent cause, with dyspnœa which was paroxysmal, but not severe. It has slowly increased in intensity up to the present time, and has become constant. He began to suffer from præcordial pain, paroxysmal in character, and increased by muscular effort, three years ago, since which time he has continued to experience it at irregular intervals On admission, Dec. 8, 1880, he complained of great dyspnœa, of pain in the præcordium, and of debility. Physical examination revealed increased strength of cardiac impulse. The area of cardiac dulness was notably increased. The apex-beat was in the 8th intercostal space, and 1½ inches to the left of the *linea mammalis*. In the 2d intercostal space, near the right border of the sternum, pulsation, thrill and a double *bruit* were obtained. Dulness also existed. A mitral regurgitant murmur was present. Pulse 104; respiration 25. Temperature normal; urine normal.

Treatment.—Potass. iodid. grs. x, thrice daily, increased gradually until, on Dec. 29th, grs. xxx were administered thrice daily. The dyspnœa persisted during all this time, and was relieved, temporarily, by spts. ætheris comp. On January 12, symptoms of iodism having appeared, the iodide was discontinued.

Jan. 28. The præcordial pain and the dyspnœa being still unrelieved, resort was had to the fluid extract of quebracho bark, which was administered in doses of 30 minims every three hours.

29*th*. After the patient had taken two doses of the quebracho he was completely relieved of his *dyspnœa*, which has not returned. The pulse, which has averaged 100 since his admission, is now 86, and the respiration which has, hitherto, been hastened, is normal. Præcordial pain remains.

Feb. 3. The quebracho was discontinued.

5*th*. The dyspnœa having returned last night, the quebracho was readministered with the same result as that above recorded.

10*th*. The remedy has been given thrice daily, since the last note, and the dyspnœa has almost disappeared. Pulse and respiration are normal.

14*th*. The patient was discharged, improved.

CASE 2. *Asthma; Emphysema; Bronchitis. Treatment with Quebracho.*—Thos. S., æt. 63; Irish, pedlar; admitted February 8, 1881. The patient has suffered from attacks of asthma for a number of years, and has been harassed by chronic bronchitis in the intervals of the asthmatic paroxysms. For two years he has suffered from gradually increasing dyspnœa, which now hardly permits of any exercise. His asthmatic attacks recur every few days without apparent regularity. He has anorexia, and has become much emaciated. His dyspnœa is now continuous, but is much increased at the time of the asthmatic paroxysms. Physical examination shows great emaciation. The facies is anxious and cyanotic. The veins of the neck are turgid. The heart's impulse is felt in the epigastrium. The thorax is distinctly barrel-shaped. The percussion resonance is vesiculotympanitic. The expiratory murmur is prolonged and low-pitched. Sibilant, sonorous, and mucous râles are diffused over the chest.

Treatment.—The fluid extract of quebracho was prescribed in doses of 30 minims, at intervals of four hours, during the day-time.

Feb. 10. The constant *dyspnœa*, due to the emphysema, has been much relieved. The patient had an asthmatic paroxysm last night, but the shortness of breath attending it was less intense than usual, and its duration was shorter than is ordinarily the case.

20*th*. The patient has had two attacks of asthma, since the last note. Each was less severe and protracted than its predecessor. The constant dyspnœa

which harassed the patient has almost disappeared under the continued administration of the quebracho thrice daily. Appetite and strength have so much improved that the patient was, to-day, discharged at his own request.

CASE 3. *Nephritis (Chronic). Dyspnœa. Treatment with Fluid Extract of Quebracho.*—Jno. M., æt. 51; English, printer; admitted January 24, 1881. The patient had always enjoyed remarkably good health up to the time of his present illness. Six weeks ago, after prolonged exposure to cold and wet, incident to a debauch, he was attacked with pain in the head, anorexia, and emesis. His ankles and legs became swollen. His urine was very scanty and high-coloured. These symptoms persisted a few days and then disappeared. Two weeks ago his feet, legs, and scrotum became swollen, he grew weak, lost his appetite, and took to the bed. The urine was dark and scanty. A week later, his abdomen also became swollen. On admission, Jan. 24, he complains of swelling of the abdomen and of the lower extremities, of dyspnœa, weakness, and loss of appetite. Ascites, with œdema of the scrotum, penis, and legs, are prominent signs. The thoracic and abdominal viscera are normal, as are the pulse, respiration, and temperature. The urine is scanty; its sp. gr. is 1014. It contains 50 per cent. of albumen (by volume), epithelial and fatty casts.

25th. Amount of urine passed, in twenty-four hours, is 16 ounces. The same clinical and microscopical characters present. *Treatment.*—Potass. acetat., ʒij; spirits æther. nitros., fl. ʒij, and infus. scopar., fl. ʒiij, every three hours.

29th. The patient now passes 30–40 ounces of urine daily, but it still contains fatty casts and much albumen. The *dyspnœa* which he had on admission is unrelieved. Fluid extract of quebracho was, to-day, ordered in doses of 40 minims, at intervals of three hours.

Feb. 2. The dyspnœa has much abated. Forty-four ounces of urine were passed to-day; albumen and casts are less abundant.

3d. No dyspnœa whatever is complained of. The quebracho is still administered, as before.

10th. The quebracho was discontinued several days ago. The dyspnœa has not returned.

17th. The patient now sits up. The sp. gr. of the urine is 1012; it contains some albumen and some fatty and granular casts.

March 2. The patient having regained his strength in large measure was discharged.

NOTE.—Quebracho has been tried by Dr. Flint in several cases of dyspnœa from phthisis and pneumonia without avail. In one case of extreme dyspnœa, from mitral regurgitation, it was very efficacious.

—

Atony of the Bladder; Recovery.

J. L——, aged fifty-seven, was admitted into Mr. PEARCE GOULD'S wards at the Westminster Hospital, on August 10, 1880, suffering from retention of urine. He was a labourer with small but very firm muscles, no subcutaneous fat, bald and gray, and looked more than his age, and had marked arcus senilis. He had always enjoyed good health until twelve months before, when he found difficulty in passing his urine. This gradually increased until the night before admission, when after a hard day's work he was unable to pass a drop. He went to a medical man, who gave him some medicine and sent him into the hospital. The "difficulty" he noticed was a slow, feeble stream, and inability to empty his bladder, with frequency of call to micturate.

On admission the distended bladder formed a prominent tumour in the hypo-

gastrium, reaching almost up to the umbilicus. The prostate felt from the rectum was hard and moderately enlarged. Mr. Gould passed without any difficulty an olive-headed catheter, No. 10 English scale, and drew off rather more than four pints of clear, acid, healthy-looking urine. The urine flowed slowly, falling vertically from the end of the catheter. The influence of respiration on the stream was evident. After the escape of about a pint the flow ceased, and the rest was forced out by the hand above the pubes, and when the pressure was relaxed air was heard to be sucked in through the catheter. The man was kept in bed on full diet, and his bladder was emptied by catheter night and morning. On August 15th a mixture containing five minims of tincture of nux vomica was ordered to be given three times a day. The catheter used was always carefully washed in carbolic lotion—5 per cent.—before being used, and lubricated with carbolic oil—10 per cent. This appeared to cause some irritation of the meatus, and vaseline was substituted for the oil, and the irritation quickly passed away. There was no sign of any vesical irritation; the urine remained clear, acid, free from mucus and albumen, and the bladder gradually regained its expulsive power. Thus, on August 15th, the patient could pass 4 oz. of urine by his own efforts, and on August 17th this had increased to 10 oz., and thus he improved until on his discharge from the hospital on September 15th there was only half an ounce of "residual urine" to be drawn off.

Remarks.—This case is an example of the extreme degree of atony of the bladder with complete retention of the urine, not unfrequently met with in connection with chronic prostatic enlargement. The daily use of the catheter has long been recognized as the proper mode of treatment for such a condition, but the occurrence of decomposition of the urine with subsequent chronic cystitis have too often prevented the attainment of a perfect result. The case illustrates one application of antiseptic surgery to urinary surgery, and its value in preventing the decomposition of the urine can hardly be overrated. The result of the daily emptying of the bladder in leading to a gradual and almost perfect recovery of the bladder's power throws considerable light on the way in which this atony of the bladder is originally produced. For it is clear that it is not by obstruction of the outflow of urine with retention and stretching of the muscular coat of the bladder, nor is it from any local action of decomposed urine; but rather, it seems, from a small primary "residue" of urine. A few drachms which the bladder cannot evacuate have a paralyzing influence upon the bladder muscle, which leads to the retention of a greater amount of urine; this, again, to further diminution of expulsive power and so on until the stage of complete retention and atony is reached. The history of such cases before they come under treatment, as well as the results of catheterism, bear out this view. The symptoms often arising from a very small quantity of "residual urine" and the importance of its relief have been laid stress upon by Sir H. Thompson. The patient attends the hospital as an out-patient every month, and up to the present time (March 2d) his condition remains as on the day of his discharge; he continues to draw off the few drachms of "residual urine" every night. The quantity has not increased since he left the hospital.—*Lancet*, March 12, 1881.

MONTHLY ABSTRACT.

Anatomy and Physiology.

Calcification of the Spinal Dura Mater.

Professors Heschl and Ludwig of Vienna have described a pathological (or rather senile) condition of the dura mater of the spinal cord, which has hitherto been very rarely if ever noticed. The discovery was made during the *post-mortem* examination of an insane and paralyzed female, aged 65. The brain was small, especially the left hemisphere, and the convolutions were very narrow. In the spinal cord, especially the lumbar region, the ganglion-cells of the anterior cornua were much reduced in number and in size; and indications of chronic poliomyelitis were present. No history of the subject—whose death was sudden—could be obtained. The spinal dura mater presented, along the whole length of the posterior aspect of its dorsal portion, a peculiar fine yellow dotting, arranged in rhomboidal figures, with their long axes lying in the direction of the longitudinal axis of the spine. The series began in the lower cervical region with an isolated group of yellow dots, four-sided, but with rounded angles, and about six-tenths of an inch in diameter. Immediately below this was a second group, rather larger, which was connected by a narrow bridge with a third. From this point, the groups became gradually closer, and the yellow dots more thickly arranged; until the series ended in a lumbar region somewhat more abruptly than at its beginning. The groups were largest between the sixth and tenth dorsal vertebræ; and this part presented the appearance of ribbon with a symmetrically dentate borders, each pair of dentations corresponding to a vertebra. Subsequent investigation showed that each dental projection corresponded to an arch of a vetebra. Here and there the dentations were prolonged on the lateral, and partly on the anterior, surface of the dura mater; but Dr. Heschl never found them forming complete rings. Subsequently to making the observation above described (in November, 1880), Professor Heschl has had examinations of the spinal meninges made in a number of subjects of both sexes, of ages varying from twenty-one to ninety-three. He finds that no extensive calcareous change of the kind described is to be met with before the sixtieth year, while a few limited and imperfectly defined spots may be observed before that age. The change is most conspicuously marked between the ages of sixty-five and seventy-five; beyond this, he has as yet met with only one case, in a person aged upwards of ninety. Microscopic examination of the spots showed an assemblage of minute points, dark, or with sharp dark outlines, in many places producing complete opacity; there was also the ordinary network of fibres of connective tissue. It was further found that, while the epithelioid lining and the innermost layer of dura mater were unaffected, it was the inner third or inner half of the membrane which contained the calcareous granules, both in and between the fibres. A careful chemical examination of the deposit was made by Professor Ludwig. On analysis, it was found to have the same composition as bone-earth; *i. e.*, to be composed of three molecules of phosphate with one of carbonate of lime ($CaCO_3 + 3Ca_3P_2O_8$). In the deposits in the dura mater, the lime was replaced to a small amount by magnesia. From a consideration of the conditions in which the calcareous deposit was found in the several subjects examined, Professor

Heschl concludes that it is a senile change, and not necessarily connected with any pathological condition of the nervous centres; and that hence it can only be called "pathological" so far as the term is applied to other changes incident to old age. It is, he says, remarkable that it has been overlooked, or at least not noticed in their writings, by such eminent anatomists and pathologists as Morgagni, Voigtel, Meckel, Andral, Cruveilhier, Rokitansky, Förster, R. Mayer, Birch-Hirschfeld, Schwann, Henle, Vogel, Kölliker, Key and Retzius, Frey, Cornil, Rindfleisch, or by any other author to whose works he has access.—*British Medical Journal*, March 5, 1881.

—

Rare Form of Intraventricular Communication.

At a recent meeting of the Vienna "Medizinisch Doktoren-Collegium," Dr. CHIARI described a rare form of communication between the ventricles of the heart, which he found in a female child aged one year, who had died of tuberculosis. During life, there were observed enlargement of the area of cardiac dulness, systolic and diastolic murmur over the origin of the pulmonary artery, and occasional cyanosis. At the necropsy, the right half of the heart was found to be in a state of excentric hypertrophy; the orifice of the pulmonary artery was narrowed; the pulmonary valves were contracted, and partially adherent. The ventricular septum presented the usual arrangement of trabeculæ, but the intratrabecular spaces appeared unusually deep; and, on closer examination, it was found that, in several of them, there was a direct communication between the ventricles. Altogether, five such orifices were found, the largest being about one-ninth of an inch wide; all were lined with a delicate endocardium. Dr. Chiari believed that this defect was to be regarded as due to arrest of development, the intratrabecular apertures which exist in the septum in embryonic life not having become filled up. Hitherto, but little reference has been made to this kind of malformation.—*British Medical Journal*, March 5, 1881.

—

The Cremaster considered as an Æsthesiometer.

The researches of Dr. JOSE ARMANGUE, to ascertain whether the cremaster could furnish an index of sensibility, have led him to the following conclusions (*El Siglo Medico*, No. 1401, Oct. 31, 1880, p. 698). 1. The maximum contraction of the cremaster is obtained upon excitation of the skin over Scarpa's triangle, as it has been already noticed by Dr. Esquierdo. 2. The other regions, according to the intensity of the reaction, are—the remainder of the thigh, excepting its external part, the anterior region of the abdomen, the internal of the legs, the external of the thigh, and the posterior of the thorax. 3. Excitation of the upper extremities, the face, the feet, and the external region of the leg, determines very feeble contraction of the cremaster. 4. Both sides of the scrotum are drawn up upon excitation of those parts which induce a strong cremasteric contraction, but the retraction is always greater on the side corresponding to that of the part excited. The half of the scrotum corresponding to the side of the local excitation only contracts when the irritated cutaneous part acts slightly on the cremaster. 5. The contraction is not absolutely equal upon excitation of homologous points, but the difference is really so insignificant, that it may be ascribed to the difference of sensibility between the halves of the body. As a general rule, the testicle which hangs down lower always exhibits the greater contraction. 6. The contraction is proportionate to the strength of the excitation, in confirmation of Paget's law, that the degree of reflex action corresponds with that of the sensations which originate them. 7. The contraction varies with the nature of the excitation, being slight when the skin is tapped with the end of

the fingers, very remarkable when the skin is scratched with the nails, and reaching its maximum when the person is tickled. Tickling, however, may easily lead us into error, as it causes laughing, which by itself elicits energetic contractions of the scrotum. 8. The contraction of the cremaster has never failed to be produced upon excitation of the proper points in sound individuals. The same may be stated in reference to the irritation of normally sensible regions of the skin in individuals with anæsthesia. 9. Some persons exhibit in their normal condition little cremasteric contraction; they always submitted, however, to the above laws, though less intensely. This individual change in the intensity of the cremasteric contraction prevents its serving as a guide to estimate the loss of sensibility symmetrically affecting both sides of the body; since, unless acquainted with the normal antecedents of the case, we cannot judge whether the diminished contraction results from loss of sensibility, or from congenital absence of reflex excitability. 10. This method may be applied to recognize the absolute loss of sensibility; for then, as it follows from the preceding remarks, there will be no contraction whatever of the cremaster, which, on the contrary, will always be more or less manifest whenever sensibility is not impaired. 11. This method may be again applied to surgical anæsthesia, and may be perhaps substituted, in regard of simplicity and reliability, for the other æsthesiometers (Schiff has given this name to the pupil, and Ludwig to the arterial tension) 12. This means is superior to the usual æsthesiometers, the model of which is Weber's compasses, because it does not require for its application conditions which are not constantly met with in every patient. The great advantage of the organic æsthesiometer is that it does not require any active co-operation of the patient; for, when once we interrogate the body, the response comes of itself, not subject to the will, intelligence, and other psychical and emotional conditions of the patient. 13. This method, finally, answers to special indications, and is not free from important inconveniences. Some of them may be, however, avoided by practice and careful application; but the method will always present two inevitable defects, namely, that it cannot be applied to the extreme parts of the body, nor to females.—*London Med. Record*, March 15, 1881.

Materia Medica and Therapeutics.

Physiological Properties of Thalictrin.

M. DOASSANS, in an inaugural thesis published in Paris, and abstracted in the *Revue Scientifique*, has given some very interesting particulars in regard to the action of the essential principle of a plant rarely found in the Pyrenees, named the Thalictrum macrocarpum, belonging to the Ranunculaceæ. The root of this plant contains two substances, which have been isolated. One is an alkaloid, to which M. Doassans has given the name of thalictrin, and which proves to be, although as yet he has only been able to obtain it in too small quantities to permit its composition to be determined, a crystallizable substance, capable of combining with acids to form crystallizable salts. The other substance is a yellow colouring matter, which apparently confers the yellow tint characteristic of the fresh section of the root. On treatment of the root with successive portions of alcohol, and with water acidulated with hydrochloric acid, this yellow substance can be obtained in a state of purity, and has been christened *macrocarpin*. Macrocarpin is neither an alkaloid nor a glycoside, but a substance which chemically resembles beberin, from which, however, it differs in some particulars; it has no therapeutic action.

Thalictrin, on the contrary, has well-defined and powerful physiological properties. If a certain quantity of the aqueous extract be subcutaneously injected into a frog a local action is immediately observed, the contractile power of the muscles becoming impaired. After a short interval the muscles contract, and the limb which has been injected becomes hard and rigid. Injected beneath the skin of a dog, it causes sharp pain, and sometimes, owing to its irritating local action, the formation of an abscess. A dose of from two to three centigrammes proves fatal to a frog in the course of three or four hours, and about ten times the quantity of the salts of thalictrin is required to produce the same effect. A dog is killed with quantities varying from two to four grammes when subcutaneously injected, but its toxic influence is much less when swallowed. The principal symptoms observed are general weakening of all the functions governed by the nervous system. The arterial pressure is lowered to an extreme degree, which is dependent, not on dilatation of the capillaries, but upon great diminution of the force of the cardiac impulses. The pulse becomes more frequent. The respiratory acts are also increased in number yet no true asphyxia is perceptible, for the arterial blood remains red, and the relative amount of oxygen it contains is augmented rather than diminished. Indisposition to perform voluntary movements is observed, but the general sensibility is not generally much impaired. The nerves preserve their action on the muscles to the end of life, and the pneumogastrics continue to act upon the heart. The muscles preserve their irritability. Death appears to follow as the result of progressive weakness of the heart, respiration continuing frequently some time after the heart has ceased to beat, which shows that the centres presiding over the respiratory movements are not so profoundly affected as those which govern the cardiac movements.—*Lancet*, March 26, 1881.

—

The Spray Question.

As to whether the spray is or is not a necessary part of the Listerian method, is a question which at the present time is much discussed, especially in Germany. There are two points of view from which this question has been looked at. First, does the spray really render inert the causes of fermentation which we know to be present in the atmosphere? and secondly, whether it does so, or no, is it necessary, or may it not be replaced by some more convenient means?

Last year Stimson[1] and others published a series of experiments which in their opinion showed that the spray was not effectual in destroying all living particles in the atmosphere. In Stimson's experiments, however, by sweeping the floor of the rooms in which the experiments were carried on, or in some other way, the grosser particles of dust were raised, and mention is specially made of these large masses. On the other hand, experiments have been performed, as for instance, by Cheyne, which show, that acting in the ordinary air of rooms or wards the spray is apparently effectual in destroying all traces of life floating in the ordinary but little disturbed atmosphere. From this point of view, it is simply a question of size of the particles which the spray meets with. If these are minute and but little compact, they will be disinfected. If they are large and dense, as will be the case if the floor be swept during or immediately before the experiment, one could not expect the spray to soak through them sufficiently during their transit. There is another way, however, in which the spray may act on these larger particles, viz., by bedewing the surface of the wound, and thus keeping up the action on the dust which began during its transit through the spray. In fact, the particle of dust already moistened, while passing through the

[1] Amer. Journal of the Medical Sciences, Jan. 1880, p. 83.

spray, falls into a thin layer of carbolic lotion and thus disinfection is completed. As a rule, however, particles of dust which are small enough and light enough to float about in the atmosphere, such particles as are present in ordinary rooms or wards will, as far as we can judge, be acted on directly in a sufficient manner by the spray, for they will not fall straight through it, but will be carried along with it after being moistened with carbolic acid before reaching the wound.

Seeing, then, that the spray is really of use in one or other of the ways, just indicated, the second question arises as to whether it is necessary, or whether some other mode of manipulation might not be more conveniently substituted for it. That the spray is not by any means absolutely essential for antiseptic work, and that aseptic results may be obtained without its use, is at once evident from the experience of Mr. Lister himself. For it must not be forgot, that it was only after several years' practice of antiseptic surgery that Mr. Lister adopted the spray, and that before that time he had been performing operations only justifiable when the causes of fermentation can be excluded from wounds. He only adopted the spray as a more convenient and certain mode of obtaining the same results which he had previously got. Before the spray period, however, he had used various precautions, such as irrigation of the wounds with carbolic lotion or carbolic oil, etc.

Mr. Lister's original method has of late been revived and advocated in Germany, more especially by Prof. Trendelenburg. For several years he has given up the use of the spray in his practice, and resorts instead to frequent irrigation of the wound with the lotion. When he has concluded the operation, he washes out the wound thoroughly with carbolic lotion, and after stitching it up, he frequently injects it by means of a syringe. A similar method has been practised by von Bruns and advocated by Mikulicz. The results obtained in this way are, as is only to be expected, very excellent; but we doubt whether we have here a better or a more convenient method than by the use of the spray itself; indeed there are two serious objections to it. In the first place, as Wernich has pointed out, the element of certainty with regard to the result is very much diminished, for one can never be sure that every particle of dust which has fallen on the wound during an operation is thoroughly acted on by the carbolic acid at the end, and it is as likely as not to happen, that the particle of dust which escapes this action is a living particle, and may set up fermentation in the wound. And then, in the second place, this free application of carbolic acid is by no means a desirable thing, for by it the tissues are unnecessarily injured and irritated, while the chance of an inconvenient absorption of the acid, and consequent carbolic poisoning is very much increased. On the other hand, the spray is really not the inconvenience which some make it out to be; it requires no extra assistant; it does not obscure the field of vision; it does not irritate the wound so much as the other method, while at the same time it adds a considerable element of certainty to the result. The form which this discussion is apt to take is a useless one, the fact being, as we have attempted to show, that, in the present state of science, if the spray is dispensed with, some other means ought to be adopted in its stead.

Whether the spray remains the best means of attaining the wished for result, purification of the air, or whether it be replaced by some other more convenient method, does not affect in the least the truth of the great principles of antiseptic surgery as enunciated and taught by Mr. Lister.—*British Med. Journal*, Jan. 29, 1881.

On Five Cases of Transfusion of Blood into the Peritoneal Cavity.

The cases reported by VON KACZOROWSKI (*Wiener Mediz. Woch.*, No. 46) were one of each of the following: Puerperal fever, great anæmia with hysteria,

phthisis, marked anæmia in a woman with fungous cervical ulcers and bronchitis, and a case of typhus fever in a female drunkard. In each of these cases, transfusion into the peritoneal cavity, according to Ponfick's method, previously described in these columns, benefited the patient, and in no case did unpleasant complications arise. One of the manual advantages of this simple mode of transfusion seems to be that little surgical dexterity is required for its performance, while it does not appear to have the inherent risks of the venous method. With antiseptic precautions, a trocar is passed through the abdominal wall in the linea alba, and, by means of a tube provided with a glass funnel, the defibrinated blood is poured through the canula into the abdomen. The researches of Bizzozero and Golgi, reported in the *London Med. Record*, have demonstrated the sound physiological basis of "peritoneal transfusion."—*London Medical Record*, March 15, 1881.

Medicine.

On the Treatment of Fever in Children.

In order to diminish fever, M. STEFFEN (*Jahr. fur kinder.*, N. S., Band xv, Heft 3 and 4), has made comparative experiments on the effect of cold baths and salicylate of soda. In all, 148 cases of abdominal typhus (enteric fever) and 30 of exanthematous typhus were treated. Of typhus abdominalis, 48 cases were treated with baths. The latter had at first a temperature of 15 to 20 deg. R. (65.75 to 77 deg. Fah.); but, as the patients could not bear them well, the temperature was in most cases raised to 28 deg. R. (95 Fah.), and was cooled down to 20 deg. R. In some cases of severe fever, sulphate of quinine, in doses of half a gramme (7½ grains), was given in the evening. Several tables are given showing the age of the patient, the day of disappearance of the fever, and the number of baths used in each case. The effect of the baths on the temperature, pulse, and respiration is described minutely. Out of forty-eight cases five proved fatal. The author is of opinion that the treatment with cold baths promotes the occurrence of inflammatory processes in the respiratory organs. Contra-indications against the applications of baths, are the frequent reluctance of patients to take them, and collapse, often relieved only with difficulty. Salicylate of soda was employed only when the temperature was above 39.0 deg. C. (102.2 Fah.). In children of very early age, half a gramme or less was given; to older ones, as a rule, one gramme; rarely two grammes. The tables show here, in the place of baths, the doses of salicylate of soda. Whilst the temperature sank in the baths, on an average, from 0.6 deg to 1.5 deg. (Cent.), the differences in the majority of cases are here marked about 2.0 deg. (Cent.). It is characteristic of salicylate of soda, that the effect is not so sudden as with cold baths. The highest point in the difference before and after the remedy occurred only after from four to seven hours. On the other hand, the reduction in the temperature lasted longer than in cold baths, and rose then gradually. In these, as well as in the first forty-eight cases, the sudden cessation of fever differs from what was expected. The conditions of pulse and respiration were the same as with treatment with water. Out of 100 patients, six died. The following secondary effects of the use of salicylate of soda were not of evil consequence, and disappeared soon after the employment of the medicine ceased: dryness and burning in the mouth (the medicine should, therefore, be diluted in at least half a glassful of sugared water), vomiting, ringing in the ears, and difficulty in hearing, delirium, more or less profuse sweating, erythema of the hands and feet, transu-

dation into the subcutaneous cellular tissue, in one case into the serous cavities, sudden collapse, which, however, can be avoided by precaution (too large doses should not be given at too short intervals, and the remedy should not be applied too long). The author has not observed an irritated state of the mucous membrane, but increased diuresis. Twenty cases of exanthematic typhus were treated with cold baths, six with salicylate of soda. The results did not differ from the above.—*London Med. Record*, March 15, 1888.

—

Dengue in Egypt.

Dr. MACKIE, Surgeon to her Britannic Majesty's Consulate, sends to the *British Medical Journal*, March 5, 1881, an interesting account of the epidemic of dengue which has prevailed recently in Egypt. It seems first to have appeared in that country in 1877, when an outbreak occurred in Ismailia. In that year, so many inhabitants of the town were attacked, that the tribunals and commercial offices were temporarily closed. It occurred again in Ismailia in the autumn of 1878 and 1879, and also to a slight extent in the autumn of 1880. The disease subsequently invaded every town and village from Alexandria to those situated in Upper Egypt. It visited Alexandria in the beginning of October; and it was in this town that Dr. Mackie and Dr. Murison had the opportunity of observing it.

Dr. Mackie tells us that the disease commences, in mild cases, with slight pains and malaise; in severe cases, with slight shivering, followed by high fever, severe pain in the head, redness, smarting, and suffusion of the eyes. The most characteristic symptom, however, is pain in the back and in the muscles and joints of the limbs. With these symptoms, the temperature of the body is increased to 104° and 105° Fahr. Dr. Mackie noticed that, in comparison with the increase of temperature, the pulse is slow, a temperature of 104° often being accompanied by a pulse of 84 or 90, although it may range between 84 and 130. The pain is special in character, and differs from that of rheumatism or neuralgia. Dr. Mackie compares it to what might be produced by a red-hot iron applied to the affected joint. The tongue is coated with white or yellow fur, and the bowels are constipated. The urine is high coloured, sometimes albuminous, rarely bloody. The skin is hot, and usually dry; the face flushed, and the throat sometimes dry, congested, and painful. In cases of ordinary severity, the fever declines about the third day, and a rash, sometimes resembling that of measles, but more frequently that of scarlatina, appears on the neck, upper part of chest, large joints, and sometimes extends over the whole body. The rash may, however, appear earlier, whilst its duration is usually limited to four or five days; it is not followed by desquamation, as in scarlatina, but, where it is well developed, is occasionally followed by the shedding of fine furfuraceous scales. Convalescence is very slow, the patient remaining weak and prostrate, often troubled with sleeplessness. Children suffer less severely than adults, and usually have a rash which more resembles measles. They convalesce more rapidly than adults. In childhood, the attack is often ushered in by convulsions; whilst, at a later age, a mild delirium is often an early symptom. Although adults suffer from confusion of ideas, and see strange people, birds, insects, etc., in their room, they are usually conscious that these figures are delusions. In mild cases, the symptoms are much less marked, and the patient is able to continue to attend to his duties, although he has much difficulty in so doing. The rash, also, is a much less prominent feature, but, in Dr. Mackie's experience, is never altogether absent. The disease is undoubtedly contagious; if one member of a family is attacked, the whole household are almost certain to suffer.

With regard to treatment Dr. Mackie and Dr. Murison both found that the administration, at the commencement of the disease, of two or three half-drachm doses of salicylate of soda gave immediate relief to the pain, and reduced the temperature. During convalescence, beef-tea and wine for food, with suitable treatment for special symptoms, such as sleeplessness, have been found sufficient. Quinine, in Dr. Mackie's hands, has not proved successful as a remedy. Fortunately, the disease never kills; although one attack will not always protect a patient from subsequent ones, it does not leave him permanently damaged, troublesome boils being the worst sequelæ observed by Dr. Mackie.

—

Catarrhal Diphtheria.

MARX, who has, under the superintendence of Professor Oertel, studied a series of these cases, defines catarrhal diphtheria (*Archiv für Klin. Med.*, Band xxvii., Heft 1, 2) as that form in which there is only superficial and limited diphtheritic membrane combined with simple catarrh of the mucous membrane, slight constitutional symptoms, inconsiderable glandular swelling, and limitation of the disease to the throat. That it is a true diphtheria, he considers, is shown (1) by its clinical character; (2) by its not unfrequently passing into the severer forms; (3) by its infective power; and, lastly (4), by its microscopic pathology. The disease begins with slight fever, malaise, and pain in swallowing. The mucous membrane of the throat at some part, generally the tonsil, is swollen, red, and has on it one or more grayish spots like hoar-frost. These spots are superficial, limited, and disappear in two to three days, rarely lasting six days; unless, as sometimes occurs, the disease passes into the severe form with thick and spreading membrane. Microscopically these spots are found to consist of colonies of micrococci, which pass through the comparatively unaltered superficial epithelial layers into the deeper layers where the cells are swollen up and contain large nuclei. After twenty-four hours, pus forms in the deeper layers, and the superficial layers are thrown off. Catarrhal diphtheria differs from the severe form in the absence of a fibrinous exudation between the epithelium, and from simple catarrh of the mucous membrane by the presence of micrococci in place of the numerous organisms in catarrhal muco-purulent secretion, such as leptothrix buccalis, oïdium albicans, etc. In the treatment of this affection, the author recommends (1) immediate isolation of the case, notwithstanding apparent mildness; (2) frequent inhalations of steam; and (3) disinfection of the mouth with gargles, etc. Astringents ought to be avoided as checking the separation of the membrane, which is furthered by a rapid formation of pus under the influence of warm inhalations.—*London Medical Record*, March 15, 1881.

—

On an Organism in Diphtheritic Membranes.

M. TALAMON communicated last month to the Société Anatomique a description of an organism which he considers to be the determining cause of diphtheria. His papers appear *in Extenso* in the *Progrès Médical* for February 12th. He obtained, by the cultivation of false membranes taken from eight undoubted cases of the disease, a fungus which consisted of long-jointed mycelial rods, and spores of two kinds: the one oval or round, and giving rise, by a process of gradual elongation, to the mycelium; the others rectangular, and showing, after a short time, minute brilliant specks in their interior, about the size of an ordinary micrococcus. These rectangular bodies he considers to be conidia; and the micrococcus-like specks which subsequently develop in them, are, he thinks, the "veritable germs of the fungus."

Rabbits, guinea-pigs, frogs, and pigeons inoculated with the fluid in which this

fungus had been cultivated, all, with two exceptions, died; and, in all cases, he obtained from some of the fluids of the body the conidia considered to be characteristic. One rabbit died with an enormous swelling of the throat, comparable to the œdema which occurs in some cases of diphtheria. In four pigeons he succeeded in producing false membranes; the inoculation, effected by scraping the mucous surface with a bistoury, and then dabbing the bared surface with the fluid in which the fungus had been cultivated, was followed by the appearance of a false membrane, which covered the inner surface of the cheeks, the tongue, the velum palati, and the upper part of the pharynx; this membrane consisted, as in the case of membranes obtained from man, of epithelial cells, fat-granules, micrococci, bacteria, and yielded, on cultivation, the characteristic organism. In the case of the frogs, the stomach was the organ which underwent a diphtheritic inflammation. Three frogs were inoculated, and died in from eight to twelve days, their tissues "stuffed" with the organism. A fourth was then placed in the water in which the other three had lived and died; after ten days, he also succumbed; and, on examination, the stomach was found intensely inflamed, and covered with false membranes, which were also seen on the peritoneum.

The author points out that, in this reproduction of false membranes, his experiments differ from that of Letzerich and Klebs, who have also described organisms as existing in diphtheritic membranes: but the fluid obtained by cultivation by these observers, though fatal to rabbits, did not produce false membranes, and killed with such rapidity, that the deaths are, with much probability, attributed to septicæmia. Undoubtedly, this reproduction of false membranes, by inoculating birds with material obtained by cultivation of diphtheritic membranes, is of great interest, and lends a definiteness to the results of M. Talamon which has been wanting in the case of other observers; knowing, however, the difficulties which surround the mode of investigation adopted, and, unfortunately, it appears to be the only one at our disposal, we shall hesitate to accept his results in their entirety. The whole subject of diphtheria, and its relation to other forms of angina, is one which urgently calls for elucidation; and we shall await with interest the further facts promised to us by M. Talamon at the conclusion of his labors.—*British Med. Journal*, March 5, 1871.

—

On a Peculiar Form of Rheumatic Fever in Childhood.

Dr. HIRSCHSPRUNG (*Hospitals-Tidende*, series 2, Band vii.) comments on the peculiarities of rheumatic fever in children, and refers to the form of the disease to which attention was first called by Meynet, which is characterized by more or less extensive affection of the sheaths of the tendons, and of the fibrous tissue. He has observed three cases. The rheumatic fever in these cases was not very intense, but was prolonged. Relapse occurs in most of the cases, and the cardiac symptoms are severe. At a varying time in the disease, swellings of various sizes, and in various numbers, appear in the tendons and their sheaths, or in parts where portions of bone lie close under the skin, as the patella, the malleoli, the spinous processes, or the skull. They are as hard as cartilage or bone. They often disappear spontaneously. In very few cases is there any remarkable tenderness or pain in the part, and only exceptionally a slight redness of the skin. The fever does not seem to have any definite relation to the outbreak, and it cannot be decided whether the deposits are confined to the region of the affected limb. In one of the author's cases, the child died of heart disease, and the necropsy showed that the nodules, which appeared to proceed from the tendons, might be regarded as consisting of a new growth of connective tissue, most like the result of chronic inflammation, with some tendency to necrobiosis.—*London Med. Record*, March 15, 1881.

Treatment of Bronchitis and Pleurisy by Pilocarpin.

M. Vulpian having arrived at the conclusion that catarrhal inflammation of the respiratory tubes, and inflammation of the serous membranes in their first stage, are those in which jaborandi or its alkaloid pilocarpin have the most incontestable use, M. TAULEIGNE states, in his graduation thesis on the subject, that he has employed them in a series of cases, of which he relates fifteen. The effect of jaborandi or pilocarpin is most prompt, and its success most evident, at the outset of the disease. A single infusion of four grammes (one drachm) of leaves of jaborandi is often enough to get rid of the affection; and M. Vulpian cites a case of well-marked pleurisy in a child, aged ten years, which, treated from the outset, yielded to the action of pilocarpin in two days. Much less is to be expected from its use in long-standing cases. The author relates from his observation of pleuritic effusion without fever or inflammation in which jaborandi has given good results, one case in which considerable effusion had for a month resisted the use of tincture of iodine, eight large blisters, and diuretics, and yielded in seven days to two doses of jaborandi. The fluid once absorbed, and pleuritic rubbing having being noted, jaborandi becomes useless. Recourse must then be had to tonics, and the application of tincture of iodine. Pilocarpin is indicated in the various forms of bronchitis. The author relates a remarkable case of chronic bronchitis, which had persisted during four years, with continued cough, difficulty of breathing, and suffocation, which recovered after the administration of two draughts containing four centigrammes of nitrate of pilocarpin. As to the mode of administration he recommends the hypodermic injection of the nitrate of pilocarpin, in doses of one centigramme. The patient should be fasting, without which the medicine is apt to provoke nausea and vomiting, as soon as sweating is established. In constipated subjects it acts badly, and it is necessary to give a preliminary purge.—*London Med. Record*, March 15, 1881.

—

The Treatment of Pneumonic Fever (Acute Lobar Pneumonia) by the Employment of the Wet-Sheet.

Dr. AUSTIN FLINT, in a recent clinic (*Gaillard's Medical Journal*, March, 1881), presented three cases of pneumonic fever, treated antipyretically by means of the wet-sheet, no other active measures of treatment having been employed. The favourable course of the disease under this treatment, in these cases, was highly gratifying. Dr. Flint said, "Inasmuch as these cases are but a small proportion of those which have been treated in my wards during the session, you may ask why the treatment has been thus limited. The treatment is, as yet, novel in this country. In relating the first two cases at a meeting of a medical society of which I am member, doubt was expressed by other members as regards a favourable influence produced by the treatment, together with distrust of its propriety and safety. I was not without apprehensions, in the first place, in respect of the treatment itself, and, in the second place, as taking the place of other therapeutical measures, notwithstanding the strong testimony of some German writers in behalf of the efficacy of cold baths in this disease. These considerations led to a careful selection of cases. The cases selected were those in which the disease was in an early stage, the patients apparently robust, the pyrexia considerable or high, and no complications existing. I am by no means sure that the treatment might not have been employed in other cases with advantage, but it was thought best to select cases in which there was the least likelihood of harm were the effect not satisfactory."

The plan of treatment was as follows: The directions were to employ the wet-sheet whenever the axillary temperature exceeded 103° Fahr. The patient

was wrapped in a sheet saturated with water at a temperature of about 80° Fahr., the bed being protected by an India-rubber covering. Sprinkling with water of about the same temperature was repeated every fifteen or twenty minutes. If the patient complained of chilliness, he was covered with a light woollen blanket, which was removed when the chilly sensation had disappeared. In none of the cases was the blanket used much of the time while the patient was wrapped in the wet-sheet. The patient remained in the sheet until the temperature in the mouth fell to 102° or lower, care being taken to watch the pulse and other symptoms. When the temperature was reduced, the wet-sheet was removed, and resumed if the temperature again exceeded 103° Fahr.

The first case entered the hospital on the third day after the attack. On the second day after his entrance the wet-sheet was employed thrice. He remained in the sheet the first time, two hours and forty-five minutes; the second time, an hour and a half, and the third time an hour and ten minutes. On the second day the wet-sheet was employed once, and continued for one hour. On the third day, the wet-sheet was not employed, the temperature not rising above 103°. On the fourth day, the wet-sheet was employed once, and continued for an hour. There was complete defervescence on the fifth day, and no return of the fever afterward. Dating from the attack to the cessation of fever, the duration of the disease was seven days. The patient had no treatment prior to his admission into the hospital. The treatment in the hospital, in addition to the employment of the wet-sheet, consisted of carbonate of ammonia in moderate doses, whiskey given very moderately, and a little morphia. The patient was up and dressed five days after the date of the defervescence. There were no sequels, and the patient was discharged well.

The second case entered hospital seven days after the date of the attack. She had no medical treatment prior to her entrance. The wet-sheet was employed on the second day after her admission, and continued for six hours. Complete defervescence took place on the third day. Recovery followed without any drawbacks. Both lobes of the left lung were involved in this case. The invasion of the second lobe, probably, was about the time of her admission into hospital.

The third case entered hospital three days after he was obliged to give up work. On the day of his entrance the wet-sheet was employed, and continued for ten hours. The wet-sheet was employed on the second day after his admission, and continued for five hours. Defervescence took place on this day. The duration of the fever was five days, dating from the time he was obliged to give up work, and seven days from the occurrence of chills and pain in the chest.

Dr. Flint said the histories of these cases as bearing upon the treatment employed, were of considerable interest. They certainly show that in cases like those which were selected, the treatment is not hurtful. More than this, they render probable the inference that the disease was controlled and brought speedily to a favourable termination by the treatment. They also go to show that the disease is essentially a fever, and that treatment is to be directed to it as such, and not as a purely local pulmonary affection. It remains to be determined by further observations how often and to what extent this method of treatment has a curative efficacy. It is also an important object of clinical study to ascertain the circumstances which render the treatment applicable to cases of pneumonic fever, and, on the other hand, the circumstances which may contra-indicate its employment in this disease.

To this series Dr. Flint adds a supplementary case of decided interest in which the pneumonia began with a well-pronounced chill, fever, headache, pain under the left nipple, cough, and a feeling of general prostration. Being without

a home, the patient spent the time from Feb. 18th to the morning of the 21st in a lumber yard without food, and with no shelter but a pile of boards. During this time there was a snow-storm of considerable severity, and the temperature fell as low as 10° Fahr. On admission there was a dusky redness of the face, and the expression was anxious; pulse 122, respiration 52, temperature 102.25°. He complained of dyspnœa, pain in left side and cough. The expectoration was semi-transparent, adhesive, and had a reddish tint. Increased vocal fremitus, dulness, bronchial breathing, and bronchophony over the left lung.

Treatment.—Whiskey, ℥ss, Ammoniæ carb, gr. v, every two hours, and a milk diet. Temperature in the afternoon, 104.25° F.

22*d*. Temperature, A. M., 99°; P. M., 99.25°. Pulse 115 and feeble. Ordered tr. digitalis, gtt. x, every three hours.

23*d*. Patient improved. All the signs of solidification are yet present, and the crepitant râle is heard behind. Pulse 70 and full. Digitalis discontinued. Respiration 32. Flush had disappeared from the face.

24*th*. Temperature, A. M., 98.25°; P. M., 98.25°. The physical signs now show beginning resolution. Dulness is less marked, bronchial respiration has given place to broncho-vesicular, bronchophony to increased vocal resonance, and the subcrepitant râle is frequently heard.

25*th*. Much better. Temperature, A. M., 97.50°. Has a good appetite, takes beef-tea and milk.

28*th*. Patient is up and dressed.

Two inquiries suggest themselves in connection with the history of this case. One is, did the disease end from an intrinsic tendency to recover in spite of the circumstances under which the patient was placed for the first two days of his illness? It is, of course, absurd to suppose that the disease was arrested by the whiskey and ammonia which were given after his admission into the hospital. The second inquiry is, did the exposure in the open air for three days shorten the duration of the disease by means of an antipyrectic effect? These inquiries are submitted by Dr. Flint without discussion for the reflection of the reader.

—

The Import of the Sweating of Consumptives.

Dr. ROUSSELOT, of Saint-Die, discusses, in the *Revue Méd. de l'Est*, some of the peculiarities of phthisical sweating, the variable period of the appearance of this symptom, and the point whether the sweating of phthisical persons is to be considered an evil symptom, and one which is to be combated. M. Rousselot believes that, in a certain number of cases, there is a correlation between the sweating and the fever. He remarks, in the first instance, that nothing is more variable than the period of appearance of the sweating in the course of a pulmonary phthisis. There is an active tubercular evolution, and a torpid evolution in some sort passive. In the second case, pulmonary lesion has no influence on the organism. It has not an effective evolution, and it may last for some time without producing fever, and, in consequence, without the procession of symptoms which are ordinarily observed with fever, and particularly in nocturnal sweating. When, on the contrary, there are, from the outset, an active evolution, nocturnal fever, and disordered condition of all these symptoms, then, in general, a hasty appearance of nocturnal sweating may be observed. In this case, the thermometer will render great service in enabling us to study the degrees of morbid combustion. The sweating, which is then very often extremely abundant, allows the elimination of a great quantity of the products of morbid combustion. It may, then, be admitted, according to M. Rousselot, that the sweating affords a derivation favourable to the fever, and does, to some extent, moderate the

symptom. If, then, in certain tubercular persons, nocturnal sweating appears, as it were, at the outset of the affection, it is because these individuals have a tuberculous evolution of an active form, and one which tends to a fluxion and precocious fever. In others, on the contrary, the evolution affects a silent, indolent, torpid form, without any recoil on the organism; or, more strictly, there are tubercles in the lung, but no tuberculous evolution, and the subject is not phthisical.—*British Med. Journal*, Jan. 22, 1881.

—

Temporary Aortic Insufficiency and Triple Aortic Second Sound.

Whether there are actual cases of temporary insufficiency of the valves of the heart caused by abnormal widening of the apertures or by disturbance of the closing mechanism (relative and functional insufficiency) has been much disputed. Although denied by competent authorities, there seems good reason to believe that relative insufficiency is not at all an uncommon condition of the tricuspid valve. Last winter, Dr. Heitler of Vienna, in an address delivered before the Medical Society of Vienna, recorded a number of cases in which he had diagnosed relative insufficiency of the mitral valve, mostly cases of Bright's disease and anæmia which he had had under prolonged observation, and in which he had had an opportunity post mortem of verifying his diagnosis. For the mitral valve the diagnosis of relative and functional insufficiency must probably in all cases remain uncertain, owing to the difficulty of excluding hæmic murmurs. With the aortic valve it is not so; and Professor DRASCHE, of Vienna, in a recent number of the *Wiener Med. Wochenschrift*, records two cases interesting in themselves and of considerable importance in relation to this question.

The first case was that of a silk weaver, fifty-five years of age, who first came under observation in June, 1879, during which month he was treated in hospital for simple mitral insufficiency. Four months later he appeared again at the hospital and was admitted. For several years, without any known cause or preceding illness, he had been affected with cough and dyspnœa, which symptoms in November, 1878, increased very much in severity, and were several times accompanied by hæmoptysis. When admitted in October, 1879, he also complained of palpitation on exertion, and of symptoms pointing to gastric disturbance. On examination the lungs gave normal resonance, here and there mucous râles, and a little crepitation, with a slight purulent expectoration tinged with blood. The liver-dulness extended three fingers' breadth below the cartilages of the ribs. The heart's impulse was felt to the left of the normal position; and the heart on percussion showed considerable enlargement in the transverse direction, very little in the longitudinal. Over the apex was heard a harsh diffused systolic bruit, with somewhat muffled second sound. The second pulmonary sound was strongly accentuated. Over the aorta both sounds were normal, the close of the second sound, if anything, slightly marked. Pulse small, but regular; temperature normal. The diagnosis naturally was mitral insufficiency. Repeated examinations during several weeks showed no essential difference in the above physical signs. The patient gradually improved, and was allowed gentle exercise in the ward. One day the patient was required for a clinical demonstration in a distant ward, to reach which he had to cross several courtyards and ascend several flights of steps. This exertion caused severe palpitation, and on examination an aortic diastolic bruit was heard in addition to the mitral systolic, the case being therefore pronounced to be one of insufficiency of the mitral and aortic valves. The patient now returned to bed, and next day the most thorough examination could detect only the mitral systolic bruit. Soon after, however, the patient had had a walk immediately before the visit, and now, on examination,

the physical signs were quite different. First, the heart's impulse was somewhat stronger and broader, and over the third left costal cartilage a fine, short, localized thrill was felt during diastole. At the same spot was heard a short diastolic sound, tailing off into the characteristic blowing bruit of aortic insufficiency. The systolic apex bruit was now of a rougher character, the diastolic sound more muffled, and the radial pulse larger and fuller. The thrill and bruit could be readily produced by exertion on the part of the patient, accompanying three or four beats, intermitting two or three, and disappearing entirely after rest in bed. The diagnosis of temporary aortic insufficiency was therefore considered justified.

The second case has both a clinical interest as bearing on the last, and also a physiological interest in relation to the production of the heart-sounds. The patient was a locksmith, aged twenty-nine, with phthisis of both lungs and Bright's disease. During the nine days he was in hospital the patient suffered greatly from dyspnœa, dropsy, and the other usual symptoms of phthisis and Bright's disease. Percussion showed the heart considerably enlarged in the transverse direction. Its action was rapid but regular, and over the apex were heard two normal but weak sounds. Over the aorta were heard with some difficulty a muffled first sound, and a reduplicated diastolic sound. With the breath held back, the second sound was heard to be replaced by three distinct short sounds. Although repeatedly examined for, no diastolic bruit was at any time heard. The post-mortem examination showed phthisis of both lungs and chronic desquamative nephritis. The right ventricle of the heart was hypertrophied by a half, and the intima aortæ and a few papillary muscles were slightly fatty. The mitral and aortic valves were in no way thickened, and under the water test the latter was found competent. The semilunar valves of the aorta were, however, peculiar, having a step-like arrangement, the posterior valve being at the normal level, the left somewhat lower, and the right lowest of all. They were likewise of unequal breadth and depth, and slightly united at their commissures.

These conditions Professor Drasche considers explain the threefold second sound, the semilunar valves being distended in order with a short but distinct interval. Apparently they were perfectly competent during life, but we can very readily understand how a disturbance of the heart's action—*e. g.*, from an obstruction to the circulation—would influence them, and as this obstruction may be temporary, so might the insufficiency produced be temporary, not necessarily leading to hypertrophy. Perhaps in the first case similar differences of position, size, and depth of the valves existed, combined, very possibly, considering the later age of the patient, with thickening and shrinking of the valves such as was probably present in the mitral valve. While admitting that the above is a possible or even probable explanation of the reduplication of the second aortic sound in this case, we would add the comment that such reduplications have, as Walshe points out, very generally little diagnostic significance. They may be produced by various causes—*e. g.*, a deep inspiration—and appear to originate from a want of synchronism in the contraction of the two sides of the heart. Why should the second sound in this case have been single at the apex? Professor Drasche says nothing of any difference between the three sounds, to explain one being heard rather than the two others, and we cannot here give Flint's explanation for the singleness in those cases of want of synchronism referred to above—viz., that the weaker pulmonary sound is not transmitted.—*Med. Times and Gazette*, March 5, 1881.

Extract of Calabar Bean in Atony of the Intestines.

From experiments on animals, which showed powerful action of the muscular coat of the intestine under this drug, SCHAEFER (*Berl. Klin. Woch.*, No. 51)

has prescribed it with excellent results in five cases of obstinate intestinal atony with constipation and flatulence. The dose was about 1.45th of a grain in glycerine, three times daily.—*London Med. Record*, March 15, 1881.

—

Intestinal Obstruction by Large Biliary Calculus.

M. DUMÉNIL presented to the Medical Society of Rouen a biliary calculus of great size, which had given rise to intestinal obstruction. A patient, aged 46, was seized on the night of the 19th and 20th July, with violent abdominal pain and biliary vomiting. The circumstances of the intestinal obstruction continued in spite of treatment for six days, when the object which had given rise to the occlusion was expelled, and health was restored. This body consisted of three biliary calculi; one large and two much smaller, but connected together in the shape of a stirrup by fecal matter and detritus, with intestinal mucus: prolonged washing separated the parts. M. Duménil discusses how this enormous biliary calculus made its way into the intestine; he cannot admit that it was by traversing the ductus choledochus, but attributes it to ulceration of the gall-bladder or biliary canals. This fact is interesting in the view of the symptoms of obstruction to which it gave rise, and may be remembered in connection with a case of intestinal obstruction. The form and condition of the calculus proved that it had remained for a long time in the gall-bladder, and its passage into the intestine showed that old serous adhesions must have existed between the gall-bladder and the corresponding part of the intestine.—*London Med. Record*, March 15, 1881.

The Pathology of Diabetic Coma.

VON JAKSCH (*Prager Med. Wochenschrift*, 1880, Nos. 20 and 21) reports a case of diabetic coma in a boy aged 13. The nervous symptoms supervened three weeks after the appearance of the diabetes was recognized; and the boy died in four days, with a rectal temperature of 33.3° Cent. (91.9 Fahr.). The blood examined during life showed destruction of the red blood-corpuscles, but no fat-drops. The urine gave a strong acetone reaction with ferric chloride. He also describes a case of acetonæmia in a boy who was not the subject of glycosuria, and who recovered completely after free purgation.—*British Med. Journal*, Jan. 22, 1881.

—

Cases of Diabetes treated with Salicylic Acid.

Dr. LATHAM had been led to try salicylic acid in cases of diabetes, from theoretical considerations, arising out of a hypothesis as to the curative action of the same drug in acute rheumatism. He contended that the substance cured acute rheumatism by entering into chemical combination with the antecedents of the *materies morbi*, which was probably lactic acid. The glucose of diabetes might have a common origin with the former, and the administration of salicylic acid might be equally serviceable in preventing its formation. He tried it in six cases of diabetes with very varying success, but still with such results as seemed to warrant further trial and investigation. In one case, the sugar had entirely disappeared. The patient, a married woman, aged 53, had, in June last, great thirst and polyuria, passing seven to eight quarts in twenty-four hours. The specific gravity was 1042, and the amount of sugar was large. The symptoms had begun two months before. Under a regulated diet, she improved much; but on December 2d, when the salicylic acid was tried, she was still passing three pints of urine during the night, of specific gravity 1025, and containing a quantity of sugar. Fifteen grains of salicylic acid were given three times a day,

and distinct improvement immediately followed. The sugar gradually disappeared, till on December 22d, the specific gravity being 1017, there was no trace of sugar, but under the microscope, crystals of oxalate of lime and of uric acid. On December 28th, she was suffering from rheumatic pains in the joints. She had experienced the same for the first time in her life a few months before the diabetes was discovered. In another case, the sugar disappeared from the urine after salicylic acid was administered; but the patient meanwhile had swelling and suppuration of the parotid gland and surrounding tissues, of which he died. In a third case, the results were ambiguous. Three other cases are at present in the hospital under treatment. Dr. Latham has not ventured in any of the cases to try the enormous doses of fourteen to sixteen grammes daily which had been given in Germany (in the Medical Clinique at Kiel; see *Berliner Klinische Wochenschrift*, 1877). In the above cases, even sixty grains a day had been sufficient to produce some of the physiological effects of the drug. He thought the remedy was of use in diabetes; but in what cases, or under what limitations, must be matter for further investigation.—*British Med. Journal*, Feb. 19, 1881.

—

On Morbid Sweating.

M. BOUVERET, in an excellent thesis on this subject (*Jour. de Méd.*, Jan. 1881), mentions some remarkable and important cases of ephidrosis or local sweating. Sweating of the legs is mentioned by Verneuil as a frequent sign of deep-seated varices: there is a notable and habitual increase of the sweat, which is often accompanied by itching, eczema, and erythema. The fact is important to note in the obscure diagnosis of deep varicose veins.

Another singular example of local sweating is parotidean ephidrosis; it occupies the region of the parotid gland, sometimes extending over the neighbouring parts, and even over a considerable portion of the face. It is not continuous, but generally intermittent, and only appears during mastication. It follows injury, such as a wound or opened abscess of the parotid gland. The duct of Steno is most often closed, but the phenomenon is not due to a transudation of the saliva, as one would suppose: it is really a local sweating of reflex origin. Facial ephidrosis is also commonly reflex, and due to excitation of the nerves of taste. The excessive secretion sometimes extends over the entire face, sometimes it remains unilateral; it has been observed exactly limited to the region of the face supplied by the supreme maxillary branch of the trigeminal nerve.

Von Graefe has seen four cases of palpebral ephidrosis. The skin of the eyelid presented well-marked hyperæmia, and, on examination by a lens, during effort or emotion, a clear fluid could be seen to escape from a multitude of little orifices. Ephidrosis may occupy one entire side of the body.

Habitual general sweating may show itself in variable and ill understood etiological conditions. One of the most interesting is that of the menopause, which M. Liégeois has studied very completely. It is well known that, at the menopause, women are subject to flushes of heat and sweating; but what is less known is, that these sweats, though independent of any other affection, may become morbid. It may not be the case always of women who no longer menstruate the hyperidrosis may come earlier, and appear when the near approach of the menopause announces itself by certain irregularities of menstruation. It is not always a passing symptom; M. Liégeois cites several cases where women were affected by it for several years; he was able, however, in most cases, to check it by the use of atropine. In most of these patients the hyperidrosis appeared especially towards the end of the night. M. Liégeois advises the administration of atropin some hours before the expected return of the sweating. Half a milli

gramme is a sufficient dose; it is well to continue the medicine several days after the cure.

Besides these forms of morbid sweating, M. Bouveret has studied those which are characterized by a peculiar colour. Chromidrosis, for example, or blue sweat, so rare that its existence has been denied by many authors, is affirmed as a scientific fact. Like sweating of blood, this singular alteration of the sweat appears most often among that set of symptoms which characterizes hysteria. Violent moral emotion is frequently the occasional cause of it; the eyelid is nearly always first attacked, and most often the lower one; blue sweat may, however, appear in other regions, the feet, the axillæ, the epigastrium, forehead, cheeks; the ears are always spared. Sometimes the blue colouration extends over large surfaces; sometimes it is developed on little patches of the integument. The colour varies from blue to black, passing sometimes to deep violet. The abnormal secretion proceeds by successive attacks, returning at variable intervals, generally preceded, as in the first attack, by disorders of menstruation, and by local derangements of the circulation or of sensibility. The colouring matter which gives the special aspect to this secretion is analogous to indigo, and its secretion seems to be produced under the influence of a vaso-motor disturbance. The same is true of hæmatidrosis, a phenomenon very much discussed, and of which the labours of M. Parrot especially have clearly shown the nature.

The sweating of blood, which shows itself nearly always in hysterical women, may occupy very variable extents of the integument, sometimes oozing out in droplets, sometimes in the form of filiform jets; the liquid is composed of blood containing all its elements. It is intermittent, proceeding by steps, coincident with painful eruptions of the skin. These hemorrhages are never alarming from their abundance; moreover, the fluxes of blood in hysteria often enjoy the singular privilege of not compromising the health or the life by reason of their quantity; for the hæmatidrosis should be regarded as a sort of hemorrhagic hysteria, all the more so as it accompanies, in many cases, hemorrhages of the stomach, of the uterus, of the bronchia, of which the neuropathic nature cannot be doubted; its existence, on the contrary, is doubtful except in hysteria.

The remarkable and nearly constant effects of atropin, administered according to the method of Sydney Ringer (attributed by M. Bouveret, *more Gallico*, to M. Vulpian), are clearly demonstrated. In a good many diseases, far from respecting profuse sweats as a useful symptom, on the contrary, it is desirable we should combat them; this is especially the case in acute articular rheumatism, where the abundant sweats may be suppressed without inconvenience.—*Lond. Med. Record*, March 15, 1881.

Cure of Lichen Ruber by Hypodermic Injections of Arsenic.

In the *Berl. Klin. Woch.* of 13th Dec. 1880, Herr KOEBNER records the history of a well-characterized case of lichen ruber exudativus treated by hypodermic arsenical injections, with a favourable result. Regarding this disease, often mistaken for eczema, and attended by progressive wasting, Hebra pronounced the opinion that when extensive it is invariably fatal, and that treatment is unavailing. Of late years, the prognosis has not appeared so hopeless, if heroic doses of arsenic be administered. Dr. Koebner thus describes his case. The patient, a carpenter, aged 39, observed in May, 1879, a red, itchy patch on the right shin; five months later, a similar patch on the left shin, then on the back, whence the trouble spread to his whole trunk, depriving him of sleep and strength. For two months he had been taking five to eight drops of Fowler's solution daily. When seen by Koebner his whole body, from the neck downwards, was studded with innumerable dark red papules, somewhat glistening, and here and there

umbilicated on their apices, occasionally covered with a fine scale, and conical in shape. They formed a sheet of eruption, discreet at parts, but mostly confluent, unmarked by any appearances of vesiculation or pustulation, and reaching down to the knees on the one hand, and the wrists on the other hand. The back was worse than the belly, and the extensor aspects of the limbs were worse than the flexor aspects. Thick infiltrated scaly patches of skin existed here and there on the most affected situations, and the penis showed a few papules. The legs were free. The patient was much troubled with scratching, a process he continued even while being examined. He was thin, wasted, and weak, but still perspired normally. All the viscera were healthy, but he showed the marks of a cured periorbital necrosis, as well as of white swelling of the left elbow joint, which was now ankylosed. The pulse and temperature were normal; there was nothing special in his previous history. He was treated by daily injections of Fowler's solution, diluted to one-third of its strength with water, the dose varying from about three to six minims of the Fowler's solution, with immediate relief to the itching. Its administration by the mouth in doses of from ten to fourteen drops a day, tried for convenience' sake, proved a failure, and the endermic applications had to be resumed. These were repeated in like doses, at first daily, then at longer intervals; and by the whole treatment, which lasted two months, the patient obtained rapid improvement, ending in complete cure. Three months later, there was no return of the disease; traces of which remained only in the form of white scars.—*London Med. Record*, March 15, 1881.

Surgery.

Gastrostomy in Cases of Stricture of the Œsophagus.

Dr. T. F. PREWITT, Professor of Clinical Surgery in the Missouri Medical College, records (*St. Louis Courier of Medicine*, March, 1881) a case of stricture of œsophagus (either cancerous or syphilitic) in which he performed gastrostomy when *in extremis*, with an unfavourable result. Dr. Prewitt tabulates fifty-nine cases of the operation and from their study deduces the following propositions:—

1st. All attempts at dilatation fail in a large proportion of cases of stricture of the œsophagus.

2d. In very few of the cases does dilatation prove beneficial, and in a still smaller number curative.

3d. In malignant and ulcerative conditions catheterization is fraught with danger, and is *absolutely contra-indicated.*

4th. In cicatricial stricture it is permissible to attempt dilatation with soft, flexible instruments, incapable of perforating the œsophageal walls.

5th. In cases of cicatricial stricture which have failed to yield to reasonable efforts at dilatation and in which the emaciation is progressive and starvation threatens, and in all cases of malignant and ulcerative stricture, as soon as solids cannot be swallowed, gastrostomy should be performed.

Serious mishap after Gastrostomy.

Dr. P. KRASKE reports (*Cent. für Chir.*, No. 3, 1881) a case in which after gastrostomy had been performed by Professor VOLKMANN, for advanced cancerous disease of the œsophagus, the patient, a man, aged 48, died on the second day in a state of coma. In the operation, which was performed under the car-

bolic acid spray, the stomach, found to be not quite empty, was fixed to the edges of the external wound by a dozen silken sutures, some of which were passed through the whole thickness of the anterior wall of the viscus. No further steps were then taken, save covering the wound with antiseptic dressing, as it was proposed to open the stomach at a later period. At the *post-mortem* examination, the condition of the wound was proved to be very good; but, on the anterior wall of the stomach, near the pylorus, and also on the left lobe of the liver, was observed a thin layer of loosely adherent exudation of a dirty-brown colour, which, on microscopical examination, was proved to contain gastric contents, namely, vegetable cells and *débris* of distinctly striated muscular fibre. The peritonitis had not extended to any other part of the abdominal cavity.

In his remarks on this case, Dr. Kraske states that the peritonitis which, though limited, was the cause of death, had been set up through the discharge into the peritoneal cavity of a portion of the contents of the stomach. Apart from the fact that the appearance of the wound, and the condition of the peritoneum in its immediate neighbourhood, forbade any supposition of the peritonitis having been the result of an infection at the time of the operation, certain constituents were found in the inflammatory exudation, as to the nature and origin of which not the least doubt could be entertained. These constituents had certainly been discharged from the interior of the stomach; and, as the wall of this viscus had not been incised, they must have passed through the punctures occupied by the sutures. This case, then, demonstrates that it is possible, after an incomplete gastrostomy, for the contents of the stomach to be discharged through the small perforations made by the sutures. This result, it is stated, is not surprising. The stomach, when dragged forwards and retained in an abnormal position, has naturally a great tendency to sink backwards; and the margins of the small punctured wounds may be thus stretched and torn so as to permit during coughing or vomiting the free passage of gastric contents into the peritoneal cavity. This accident, it is evident, is the more likely to occur when the stomach is well filled, but still cannot be effectually guarded against by operating on a stomach with but scanty contents.

Dr. Kraske, in considering whether and how this accident could have been prevented, states that it occurs at once to the surgeon that the wall of the stomach might have been transfixed through its external and middle coats only, the mucous layer being left intact. It has been proved, however, that this is not a safe course, since the stomach, in the course of a very few hours after the operation, tears itself away from the sutures, and falls backwards to its normal position. The danger of discharge of the gastric contents might be certainly prevented by rejecting sutures, and by attempting by some other means to keep the anterior wall of the stomach in sufficiently prolonged contact with the external wound for the establishing of firm adhesions. How such a plan, which, as is well known, has been carried out by Volkmann with much success in the treatment of hydatid cyst of the liver, is to be applied to so movable an organ as the stomach, is a question that has yet to be settled.

It is next considered whether, with the object of preventing extrusion of the gastric contents along the sutures, gastrostomy ought not to be always performed in one stage. There can be very little doubt that this accident might be prevented by at once incising the stomach after it has been fixed by sutures, and by washing out its interior. Dr. Kraske does not give any decided opinion as to the necessity of giving up in future the operation of gastrostomy in two stages; but to those who practise the single operation, he recommends that the wall of the stomach be transfixed by two sets of sutures, the first involving the serous and

muscular layers only, and the second, applied after the viscus has been incised and opened, involving also the mucous coat.—*London Med. Record*, March 15, 1881.

—

On Colotomy.

In an article in the *Hospitals-Tidende*, series 2, Band vii., Dr. C. STUDSGAARD examines the merits of the two operations—anterior colotomy or laparocolotomy, and posterior or lumbar colotomy. He gives the preference to the former (Littré's method), especially since the use of antiseptics has materially diminished the danger of opening the abdominal cavity. Costallat's advice to perform the operation in two stages—the bowel being first opened some days after the incision is made, in order that the edges of the incision in the abdomen may granulate before they come into contact with the fecal matter, and that the risk of diffuse inflammation may be diminished—he regards as rational, provided that the urgency of the symptoms of ileus do not demand immediate relief, in which case he considers it quite superfluous to open the bowel with the cautery instead of the knife. Cauterization of the wound with a 10 per cent. solution of chloride of zinc is sufficient to obviate infection, the more so as it is only in exceptional cases that fecal matter passes in the first days. The incision in the intestine should be 1¼ inches long; not smaller, in order to give room for the passage of feces; nor, if possible, larger, lest prolapse of the mucous membrane of the bowel should occur. The size, however, which should be given to the opening in the bowel must in some measure depend on the indications for the operation. In cases where it is difficult to be certain that the function of the fistula will be permanent, Dr. Studsgaard has modified the application of sutures to the intestine. The lowest sutures are introduced into the intestine in such a way, that a great part in front lies free between two corresponding sutures, while the posterior ones are passed through the bowel closer to one another in the neighbourhood of the mesentery; in this way, a kind of spur is left at the lower angle, which will obstruct the passage of feces into the rectum. Dr. Studsgaard finally relates seven cures of anterior colotomy performed by him in the Communal Hospital of Copenhagen. Of the patients, two died in the hospital and five were discharged, one of whom died six months afterwards of metastatic cancer.—*London Med. Record*, March 15, 1881.

—

Healing up, under Antiseptic Precautions, of Fresh and Dead Tissues in Serous Cavities, and the Subsequent Fate of these Tissues.

Starting from the observation that foreign bodies and ligatured portions of tissue, *e. g.*, the returned pedicle in ovariotomies, may without injury to the patient be left in the body, ROSENBERGER (*Archiv für Klin. Chir.*, Band xxv. Heft 4) has performed certain experiments with living material, mostly pieces of muscle, but also whole organs (the kidney). The results of these experiments are as follows. With antiseptic precautions, pieces of living tissue heal up in the serous cavities of animals, either quite without, or with only the very slightest reaction. After a time, these pieces disappear without leaving a trace. The tissue need not be from the same animal—need not even be from the same species of animal. The process is not one of digestion, but commences with the encapsuling of the tissue on the third or fourth day. From the capsule, cells wander into the inclosed tissue and break it up. A rarer method is for the piece of tissue, after five or six days, without having caused any irritation in the peritoneal cavity, to have still little or no union with its surroundings; the

capsule becomes firmer, receives a capillary network, and the tissue thus nourished, lives on. This method occurred only in the case of animals of the same species. A third method is precisely the same as the last, with the exception that, in the centre of the piece, probably owing to insufficient nourishment, a pus-cavity is found.—*London Med. Record*, March 15, 1881.

—

Amputation of the Breast by a Bloodless Method.

In No. 30 of *Centralb. für Chir.*, 1880, Leisrink has mentioned a screw-compressor, which he has used twice in removing the breast, to make the operation quite bloodless. This apparatus consists of a flattened U-shaped iron, the vertically standing arms of which are placed in the holes of a straight iron staff. The latter, as soon as the female screws are applied to the vertical arms and screwed, presses the base of the breast against the horizontal bar of the apparatus, making the breast free from blood. SZUMAN recommends (*Ibid.* No. 40) a process to make the amputation bloodless, which can be used not only with a pendulous breast, but with any other. He operated on a medullary sarcoma of the breast with a broad and flabby base, in the following manner. The base of the breast was pierced close to the thorax three times by means of a long straight needle, which was armed with a double and very strong silk thread; the threads were then fastened in such a manner that the base of the breast was divided into four parts, constricted by ligatures, and thus made free from blood. Above the ligatures, the tumour was removed, the veins tied, and the wound sewed together. Complete union by first intention was obtained.—*London Med. Record*, March 15, 1881.

—

Chlorate of Potash in acute Blennorrhagia.

Dr. GAMIR (*El Siglo Médico*, October, 1880), of Havana, reports four cases of acute gonorrhœa, which he treated with chlorate of potash. The average duration of treatment was ten days in each case, and the salt was prescribed in doses of from 10 to 20 grammes daily.—*London Med. Record*, March 15, 1881.

—

Trephining of the Ilium.

Dr. G. FISCHER, of Hanover, has recently reported (*Deutsche Zeitschrift für Chirurgie*, Band xiii., Heft 506) a case of large psoas abscess from spinal disease, in which an opening made below Poupart's ligament had not been sufficient for a free discharge of the pus. As fluctuation could not be felt in the lumbar region, and the extremity of a long probe passed into the cavity of the abscess could not be felt under the skin, Dr. Fischer, in order to make a free counter-opening, trephined the ilium. The soft parts having been divided near the postero-superior angle of the bone, the ilium was perforated, and pus at once flowed through the opening. There was very slight reaction after this operation. The patient, whose condition was weak for a time, died ten weeks later from tuberculosis.

Two other cases of trephining of the ilium have since been published by Dr. M. RIEDEL, of Göttingen (*Centralblatt für Chirurgie*, No. 52, 1880).

A boy, aged 16 years, came under treatment in October, 1877, in a very exhausted condition, and with an open abscess of long standing at the back of the thigh. On examination, whilst the patient was under the influence of chloroform, a long probe was passed first upwards and forwards to the upper third of the front of the thigh, and then upwards under Poupart's ligament, and along the inner surface of the ilium, until it grated against a bare and rough osseous surface at a distance of about two inches and a quarter from the postero-superior spine.

As the spine and the sacro-iliac articulation seemed to be quite healthy, this patch of bare bone was regarded as the starting-point of the abscess. The ilium was trephined at this point, and vent given to some very putrid pus. Erosion of bone was found on the inner surface of the bone, but not any sequestrum. The sacro-iliac joint was found to be quite healthy, but a small fistula was observed leading upwards to the spine. The patient made a very slow recovery after this operation. After a treatment of nearly two years' duration, the patient was discharged as convalescent. The back was then straight, but there existed several open and scantily secreting fistulæ. When seen again a year later, and after he had been working in a factory, the patient presented a well-marked spinal curvature in the lumbar region. The numerous fistulæ at this time had almost all closed.

The subject of the second case—a boy, aged 15—was admitted into the Göttingen Surgical Clinic on June 14, 1880. He had fallen on the left hip about eight weeks previously, and a few days later he became feverish, and began to suffer pain at the seat of injury. When first seen by Dr. Riedel, the thigh was flexed on the pelvis at an angle of 50 deg., and some swelling could be observed in front of the hip. Two months later, in consequence of fluctuation having been made out, an incision was made into this swelling, at a point just below the antero-inferior spine of the ilium. Through this opening the finger could be passed into a cavity on the inner surface of the ilium, which cavity was surrounded by newly-formed bone, and contained a small sequestrum. After unsuccessful attempts to drain the abscess by an anterior opening by the side of the rectus muscle, and a posterior opening made through the muscles on the outer side of the thigh, the ilium was trephined at the seat of the disease. This operation was followed by a free discharge of pus, and subsequently by recovery of the patient

This operation, Dr. Riedel states, is not attended with difficulty. Severe hemorrhage may be avoided by tearing through, instead of incising, the subcutaneous soft parts, and there is but slight reaction after the proceeding. The propriety of Dr. Fischer's indication for this operation is questioned by Dr. Riedel. The former surgeon would trephine the ilium, in order to obtain the best possible outlet for the purulent contents of a pelvic abscess. But when such abscess is due to vertebral disease, the best situation for a counter-opening, or an opening for drainage, is just above the crest of the ilium. In order to make an incision into the abscess in this region without any danger, the surgeon need not insist on fluctuation, but should cut down on the end of a long probe introduced, *not* below Poupart's ligament, but through a puncture made above this structure, near the antero-superior spine, the probe being then carried backwards and outwards until it can be felt under the skin of the back of the patient. The danger of wounding the peritoneum, in case of no abscess existing in the lumbar region, is not very great, provided the sound be introduced carefully. An incision made above the crest of the ilium at its posterior portion is regarded by Dr. Riedel as the best means of draining a pelvic abscess consequent on vertebral disease, and far preferable to a perforation in the ilium. Trephining of the ilium, it is held, is indicated in cases of abscess dependent on disease either of the inner surface of this bone, or of the soft parts contained within the pelvis. In such cases, the operation not only affords a free outlet for pus, but it exposes to direct attack the seat of the primary disease.—*London Medical Record*, March 15, 1881.

—

Pulsating Encephaloid mistaken for Aneurism; Ligature of Right Common Carotid Artery.

Surgeon M. D. MORIARTY reports (*Indian Med. Gazette*, Feb. 1, 1881) the case of a man, aged 45, who applied to him, Feb. 5, 1880, with the following

history. About sixteen years before he noticed a pulsating tumour of the size of a small walnut, seated immediately below his right ear, which caused him no great inconvenience. About two months ago the tumour became painful and began to increase in size, and the right side of his face became paralyzed.

On examination a tumour, the size of a small orange, was found to occupy the right parotid region; it extended upwards in front of the ear to about the level of the temporo-maxillary articulation, and behind the ear to a similar level; its lower border was about half an inch above the level of the upper border of the thyroid cartilage. The lower part of the ear was bulged upwards, the external auditory meatus being almost closed. The tumour was more or less globular, with a slight irregularity in the shape of a little prominence at its lower posterior part. On the upper and back part of the tumour were two small blue veins; the skin over the tumour was somewhat congested, especially posteriorly, but was freely movable. The tumour was more or less movable from side to side, its base however appeared to be fixed; it pulsated, the pulsation being systolic and distensile, and on auscultation a well-marked bruit was heard. To the feel the tumour was rather tense, but apparently fluid, the posterior part being perhaps a shade less tense than the rest of it; pressure on it somewhat diminished its size. The right common carotid beat more vigorously than its fellow of the opposite side. Occlusion of it diminished the size of the tumour and completely arrested its pulsation. (No note was made as to whether the consistency of the tumour was also altered, but it must have been to some extent). When the artery was let go the blood entered the tumour with a soft distensile pulsation, and the tumour returned to its original state. Above the tumour the right temporal artery beat more feebly and a little later than the left. Pressure on the tumour, especially in front of the antitragus, caused pain. There was complete right facial hemiplegia; the uvula was straight; the right side of the throat including the tonsil bulged considerably inwards; the tonsil was hypertrophied, and pulsated, the sensation of fluid from within the throat was not however very marked; there was no marked interference with respiration or deglutition; the heart and large vessels appeared to be healthy; the patient never had syphilis, and had only once or twice in his life tasted spirits; the lymphatics in the neck were apparently healthy.

The diagnosis was aneurism, probably of the internal carotid.

On 18th February Mr. Moriarty ligatured the right common carotid just above where it is crossed by the omo-hyoid muscle; and all pulsation in the tumour ceased. On 28th of Feb., slight pulsation was observed in the tumour which had never hardened as a consolidating aneurism should.

The patient kept in pretty fair health up to October, then the symptoms of malignant disease became unmistakable,—rapid growth, implication of the skin, fungation, severe pain, occasional hemorrhages, glandular implication, fetor, emaciation. He died on 30th November.

On examination of the body next day, the disease was found to be encephaloid of the parotid gland. Peripherally, to a depth of about half an inch, the tumour looked like congested cerebellum; centrally it was like boiled udder (Erichsen); the external carotid was lengthened, it ran at first superficial to the tumour, but afterwards sank into it. The tumour extended very deeply, the pinna was quite separated from the external auditory meatus, and the bone all round the latter was eaten away and covered with a horribly fœtid slough. The tumour extended almost to the jugular fossa, it encircled the internal carotid for a small part of its jugular course; lower down it touched the transverse process of the atlas.

In this case most of the symptoms of aneurism were present, but were defi cient in quality, especially was this true of the pulsation which was not quit what the thump of an aneurism should be.

[The difficulties of diagnosis in cases like the above are oftentimes very grea and in this connection a series of very excellent papers on this subject by Dr Stephen Smith, of New York, in the *American Journal of the Medical Science* for April and Oct. 1873, and Jan. 1874, may be read with interest.—ED.]

—

On the Ox Aorta Ligature, and on the Variability of Catgut.

Mr. RICHARD BARWELL read, at a recent meeting of the Royal Medical an Chirurgical Society (*Lancet*, March 12, 1881), a paper on his experience wit the ox aorta ligature and on the variability of catgut. The object of a pap which Mr. Barwell read two years ago was, first, to point out the cases of aort aneurism which might be benefited by deligation of the right carotid and sub clavian; secondly, to show the advisability of leaving all the coats of arteri tied in continuity intact; thirdly, to introduce a flat ligature to carry out th object. The experience, necessarily small, which he could then adduce he no supplements by two additional cases of aortic aneurism treated by tying th above-named vessels with the ox aorta ligature; thus there are three in all. His own case; lived sixteen months in fair health and comfort. 2. A case Dr. Lediard (now of Carlisle); lived ten months. 3. A case by Dr. Wyeth New York; now alive and in good health. Besides these Mr. Barwell repor a case in which he tied for aortic aneurism the vessels on the left side of the neck The operation failed to prolong, but he does not know that it shortened, life. Th patient survived thirty hours. The parts of his first case, and of Dr. Lediard case (by the kind permission of Dr. Hopkins), were exhibited, as were al certain specimens removed from the last case. The arteries of the first were in jected; the carotid ligature was *ab origine* tied too loose. It was the first arte Mr. B. had tied with the ox aorta, and he attributed the almost immediate retu of temporal pulse wrongly to free collateral circulation. The loop of ligatu probably remains on the vessel. The subclavian is quite closed, and, being sl lengthwise, shows the tunics entire. Collateral circulation is well establishe Of the second case Dr. Lediard writes: The aneurism is filled with very fir clot. Nothing could have been more satisfactory than the action of your ligatu in this case. The vessels were entirely occluded, there being no trace of th bands seen, but a firm clot above and below the seat of constriction, such as usual in vessels tied in continuity. The parts from the last case are the su clavian, showing where tied no injury to any of the coats—the severed ligatu from that artery; the other ligature with the knot entire, and showing no te dency to loosen. Four other vessels have been tied with this ligature—two ilia (Mr. Holmes and Mr. Johnson Smith), two femorals (Mr. Bellamy and Mr. Ba well); in these four cases the aneurisms did perfectly well, the wounds healed once, and nothing more was seen of the ligature.

The twelve deligations are more than sufficient to show that the ox aorta lig ture becomes absorbed with sufficient slowness to be perfectly reliable in tyi vessels in continuity. They show this with the more force because this mater is not prepared, the ligatures are cut from the fresh aorta and dried, hence th are uniform. What has happened with those that have been employed will ha pen with all. This power of becoming gradually absorbed is common to all t soft connective tissues, provided they are perfectly fresh—*i. e.*, not decompose The submucous tissue of sheep's intestine, of which catgut is made, would, if were dried while fresh, act like other soft connective tissues, with no need wha

ever for after preparation. But in the manufacture of catgut this structure is separated from the rest by processes of scraping, a procedure which would be impossible unless the intestine were to some extent decomposed. The various modes of preparing catgut into ligatures are devices for getting rid of the results of this decomposition. Catgut sutures, more easily watched than ligatures, dissolve in very various periods, though prepared in identically the same way. One of the chromic acid processes gives cords, dissolving some in nine, some in nineteen days. The usual (old) method has supplied Mr. B. with sutures, some of which have dissolved in forty-eight hours, some remained persistent, and had to be cut away on the fourteenth day. This results from the various degrees of decomposition in the catgut itself; it cannot happen with tissues that are fresh and require no after-elaboration. When a piece of catgut is buried deep round a large vessel, we cannot be more sure of its behaviour than we can predict the duration of the sutures; nor can we deduce from the good behaviour of certain such ligatures that the particular piece supplied us will act properly. For tying large vessels near the heart, or lying deep, a material whose action is more uniform, which is therefore more reliable, is essential.

Mr. LISTER said it was interesting to learn that the tissue of the aorta resisted absorption for so long a time. He disputed the statement that the preparation of catgut by scraping was due to putrefaction. On the contrary, the fresher the intestine the better the quality of catgut. The rapidity of absorption of improperly prepared catgut was not due to the state of putrefaction, but to the difference between cellular tissue and aortic tissue. Unlike Mr. Barwell, he had found old catgut less readily absorbed than new catgut; but by the new mode of preparation he had described both kinds were brought to the same level in this respect. Speaking of the desirability of dividing the inner and middle coats of an artery tied in continuity, he said that in one of his early experiments (using a ligature of a strip of ox's peritoneum) he had tied the carotid of a calf without dividing the middle coat; but this did not prove that the division of the inner and middle coats was not essential. Indeed, general experience went to show the desirability of such division—incomplete ligature or insufficient injury to the coats being followed by a tendency to the opening up of the vessels. He always applied the catgut ligature so as to divide the inner and middle coats; although whether this was absolutely necessary when the catgut was of the best form—(*i. e.*, not too readily absorbed), he was not prepared to say. Referring to the case recently related by Mr. Treves, where the opening up of the carotid artery after antiseptic ligature was ascribed to the rapid healing of the wound, the subclavian in the same case being perfectly occluded, and the wound not antiseptic, Mr. Lister showed a specimen where the external iliac had been tied for femoral aneurism. An antiseptic silk ligature was used, and the wound followed an antiseptic course. The external iliac artery was wholly occluded. A small knot of silk remained, and a minute abscess occurred at the seat of ligature. Death took place one year after ligature. Here was evidence of extensive obliteration following the application of an antiseptic ligature. On the other hand, secondary hemorrhage from the distal side followed sometimes on the use of ordinary ligatures, from absence of coagulation; and such cases proved that suppuration around the vessel did not invariably lead to obstruction. That failures in occlusion might follow the use of catgut, when not of proper quality, he was fully aware. Such failures were recorded, but the multitude of successful cases were not. He felt sure that if all the cases were reckoned in which the catgut ligature was applied to arteries in their continuity with strict antiseptic treatment, the results would compare very favourably with other methods of ligature. But if surgeons use the catgut ligature and allow the wounds to putrefy, good results could hardly be

hoped for. Such cases as those recorded by Mr. Bryant were due to the luck chance that union by first intention took place in the deep parts of the wound thus preventing putrefaction around the ligature. He ventured to think that su geons who undertake such operations are bound to take measures to avoid putre faction. At the Cambridge meeting of the British Medical Association h adduced a long series of cases in which no putrefaction occurred, and since the he had had many more cases without putrefaction in a single instance. He di not state this in a spirit of boasting, but simply as a matter of duty. His case at King's College Hospital were not dressed by himself, but by the house-surgeo and dresser, to whom the praise was due. Surely if such results can be obtaine it was worth while to master the simple measures of preventing putrefactio By the use of such measures the two great dangers to ligature of arteries in the continuity—viz., secondary hemorrhage and diffuse suppuration—may be avoide and these were objects deserving the best attention.

Mr. TREVES said that in the case he had reported where the carotid after ant septic ligature became partially reopened, the catgut was of good quality and th coats divided. The small abscess at the seat of ligature in Mr. Lister's case iliac ligature was hardly consistent with an absence of inflammatory reactio With regard to the mode of tying arteries alluded to by Mr. Barwell, he ha found by experiment that it was almost impossible to divide the inner and midd coats when a double hitch was made in the ligature before tightening it.

Mr. LISTER pointed out that the abscess referred to was of very minute siz and could not have produced any inflammatory action around the vessel.

Mr. HEATH remarked that in one of Mr. Barwell's specimens the caroti artery which had been ligatured was quite pervious, and showed no trace at a of any ligature. The subclavian in the same specimen was completely oblite ated. Was there division of its internal and middle coats? He doubted if th surgeon could so graduate the force he applied as not to cut through the inner an middle coats.

Mr. BARWELL, in reply, said that much depended on the mode in which th ligature was tied. He had found that, owing to the roughness of catgut, it wa difficult to tell from the sense of resistance whether the artery was being suf ciently pressed on or not. The carotid artery in the specimen alluded to by M Heath had been incompletely tied. The condition of the coats of the subclavia was not ascertained in that specimen; but in another the internal and middl coats were not divided. By means of flat ligatures it was hardly possible to t the vessel so tightly as to divide the inner and middle coats. He had been struc with the fact that the recorded cases of ligature of the largest vessels were fat from secondary hemorrhage, and it struck him that this would be obviated b keeping the artery entire. He did not at all suppose that this could only be don by means of the ox aorta ligatures. Mr. Pollock last year tied the subclavia and carotid successfully, using ligatures of kangaroo tendon. Professor Wyet had used ligatures of the whole thickness of the aorta. Why should not catgu act in the same way? He certainly thought the preparation of catgut wa attended by putrefaction, and had attributed its unreliability largely to this. On surgeon used chromic acid many times the strength of that used by Mr. Lister t make the catgut reliable. In the old methods of preparation Mr. Lister had go perfectly reliable ligatures; but in one case where he had supplied Mr. Pember ton with such a ligature a large abscess formed, and the ligature came away. I a case of double popliteal aneurism Mr. Bellamy tied one femoral with the aorti ligature, and with good result. The same operation performed on the opposit leg with the chromic catgut ligature supplied by Mr. Lister was followed by th formation of a sinus leading down to the ligature, the rest of the wound healin

by first intention. These different modes of preparing catgut ligatures may suit one or other form of catgut, but not all, and therefore he said the catgut ligature was not a reliable one. Nor did experiments in blood serum touch the point, for the experiments should be made in the living body in the midst of the tissues.

Midwifery and Gynæcology.

The Treatment of Extra-Uterine Gestation.

At a late meeting of the Medical Society of the County of New York, Dr. WILLIAM T. LUSK read a paper on the above subject. In commencing he alluded to the fact that extra-uterine pregnancy was a condition which existed much more frequently than was formerly supposed to be the case, and stated that for its present knowledge of the subject the profession was greatly indebted, first to the late Dr. John S. Parry, of Philadelphia, and, secondly, to Prof. T. Gaillard Thomas. As cases of this kind were now known to be comparatively common, the question of treatment, therefore, assumed a high degree of importance.

The natural termination of tubal and interstitial pregnancy was by rupture of the sac, hemorrhage, peritonitis, and death; although there was a certain number of spontaneous recoveries on record, either through the mummification of the fœtus or the formation of a fistulous tract through which it was gradually discharged in small portions. In ovarian and abdominal pregnancies the death of the fœtus might take place either prematurely or at full term, and in the majority of cases it resulted in suppuration, which was almost sure to be followed by peritonitis and the death of the mother. Occasionally, however, the latter survived, and a fistulous opening was established into the vagina or rectum, or through the external abdominal walls, by means of which elimination took place. But this process of elimination was ordinarily a very slow one, and in the greater number of instances the patient required active interference on the part of the medical attendant, or else death would eventually ensue from blood-poisoning or exhaustion. Again, in a certain proportion of cases the fœtus after its death became coated with a bony or earthy crust, and remained as a comparatively innocuous tumour during the rest of the woman's life. Its presence under such circumstances did not prevent the occurrence of pregnancy subsequently.

The treatment of extra-uterine gestation, Dr. Lusk continued, varied according to the stage of pregnancy. In cases of early gestation the indication was plainly to destroy the life of the fœtus, and in order to accomplish this without injury to the mother a number of methods had been suggested and practised. One of the most simple was the puncture of the sac, and this could usually be easily effected by means of a trocar introduced through the walls of the vagina or rectum. It was true that a number of recoveries were on record in cases where this plan was adopted, but the results, as a rule, were unfavourable. The second method mentioned was that of injecting poisonous solutions into the sac by means of the hypodermic syringe. The first used was one-fifth of a grain of sulphate of atropia in a small quantity of water; but Friedereich had substituted the fifth of a grain of morphia for this, and had reported two successful cases under its use.

The third method was that resorted to by Thomas, namely, the use of the galvano-cautery. One case barely escaped resulting fatally in his hands, however, and in the latest edition of his work on diseases of women (which contained a chapter on extra-uterine pregnancy) he recommended Paquelin's cautery. It

was to be employed only after the pregnancy had given rise to symptoms trouble. The fourth and last method considered was the use of the faradic cu rent. It was to be kept up from five to ten minutes through the seat of t product of conception, and repeated from time to time, if necessary, for one two weeks, until the shrinkage of the tumour left no doubt that the passage of t current had produced the desired effect. Dr. Lusk then related in detail t history of a very interesting case in which he had called Dr. Thomas in cons tation, and in which the faradic current had been employed with complete su cess. The use of the faradic current, in this connection, he continued, the pr fession owed to Dr. James G. Allen, of Philadelphia, who reported two cas successfully treated by it in 1872. This method, Dr. Lusk considered, offered much better chance of recovery than any other, and one great advantage of was that it was accompanied by no drawbacks. So far as he knew, it had no been resorted to in nine cases, and in every one of them the result had be successful. When it was remembered that in one hundred and fifty cases co lected by Hume there were only seventeen recoveries, the advance that had be made could be better appreciated. The subsequent treatment was that f peritonitis.

The second class of cases was that in which gestation was in an advanced sta and the fœtus was still living. Here symptoms of exhaustion finally came o and the patient was in great danger. Laparotomy in such cases, Dr. Lu thought, ought to enjoy the highest confidence of the surgeon, provided its p formance did not increase the jeopardy of the mother. Parry had report twenty cases of primary operations, with eight children and six mothers save but after a careful study of these cases he had found that five out of six of t maternal recoveries ought really to be stricken out. The great and unavoidab danger in such operations was the difficulty or impossibility of removing t placenta.

Finally he considered the class of cases in which gestation was prolonged af the death of the fœtus. Under these circumstances it was a well-established r not to operate during the continuance of labour-pains. The fœtus might at leng become converted into a hard, innocuous mass, as mentioned at the outset; b this was the exception, and not the rule. Most commonly it underwent ma ration, and the patient sooner or later began to suffer from exhaustion a symptoms of septicæmia. In some cases a fistulous opening was formed into t vagina, into the rectum, through the abdominal walls, or even into the bladd Under such circumstances the treatment consisted in the enlargement of the fis lous tract, and the extraction of the fœtus piece-meal through it.

Secondary laparotomy was a justifiable operation, and out of thirty-three ca reported there had been nineteen recoveries. Of the two great dangers of t primary operation, hemorrhage and septicæmia, the first was very greatly dim ished by the death of the fœtus and the changes ensuing upon it, and the seco could be avoided to a considerable extent by the judicious use of the antisep precautions now at the surgeon's command. When circumstances permitt therefore, it was advisable to delay operative procedures until obliteration of maternal vessels had taken place. Whenever the operation was demanded the condition of the patient, however, antiseptic surgery offered a fair chance success.

The paper being before the society for discussion, Dr. JACOBI remarked t he had had but one case of extra-uterine pregnancy in his own practice. T occurred some time ago, and he had not treated it by the method so high recommended by Dr. Lusk, although he was happy to say that the result h been a favourable one. The patient was probably at the beginning of t

third month of gestation, and he had punctured the sac through the vaginal walls. He had also made a second puncture two days afterward. Half a year later, when he examined the patient, he had found a hard substance to the left of the uterus which to the touch reminded him of cicatricial tissue in any other part. Even to this day, although it was seventeen years since the operation, the fundus of the uterus was drawn over to the left by means of the contraction that had resulted, while the cervix pointed decidedly toward the right. With his present knowledge of the subject, and especially after listening to the results mentioned by Dr. Lusk in his paper, he would undoubtedly employ the treatment by the faradic current if he were to meet with another similar case.

Dr. ROCKWELL stated that he had successfully employed electricity in the treatment of three cases. The first was that of Dr. McBurney, which had been alluded to by Dr. Lusk, and which, having been published in full in the *New York Medical Journal*, was well known to the profession at large. The correctness of the diagnosis had been disputed in some quarters, but he did not propose to discuss this point. The second case was that of Dr. Billington, also mentioned in the paper of the evening, and the third he had seen quite recently. Dr. Lusk had spoken particularly of the use of the faradic current, but it seemed to him that the galvanic current would prove the most efficient in destroying the fœtus. In Dr. McBurney's case this was employed, and two applications were made. Before it was resorted to Dr. Thomas, who was one of the consultants, asked him if he could kill the fœtus in this way without doing injury to the mother, and he replied that he thought he undoubtedly could. The result, as was well known, was entirely satisfactory. In Dr. Billington's case he had made but a single application of electricity, and did not know how many had been made subsequently. In the third case there had been but one application—of the galvanic current—altogether, and the recovery had been as successful as in the other instances. These three cases constituted all his experience in regard to this interesting subject, but they at all events went a considerable distance towards settling the point that the fœtus might be destroyed without injury or danger to the mother.

Dr. BILLINGTON said that in his case a positive diagnosis was made by Dr. Thomas, whom he called in consultation, and that he had made four applications after the first one by Dr. Rockwell. The first three times he employed fourteen or fifteen cells, but the last time he used the full strength of the battery, thirty-six cells.

Dr. MUNDÉ had seen three cases of extra-uterine gestation altogether. The first was in the service of Scanzoni, and was fatal. It was a case of ventral pregnancy, and the patient went beyond full term. The second occurred in Braun's clinic. The pregnancy had originally been either interstitial or tubal, and the fœtus at length escaped into the abdominal cavity. The woman was in a very cachectic condition, and it was decided to wait till her death before operating for the purpose of saving the child's life. As soon as she expired laparotomy was performed, but the child which weighed nine pounds, was asphyxiated. The third case occurred in his own practice, and the circumstances were peculiar, the fœtus escaping through the uterine canal, as in Dr. McBurney's case. Before he met with it he had been disposed to doubt the accuracy of the diagnosis in the latter, as he could not understand how the fœtus could pass through the undilated uterine canal. Now, however, he was quite willing to take back all that he had said upon this point, for the case in his own experience had completely convinced him that such a thing was quite possible. In this case he had sounded the uterus with the probe and found it empty, and yet twenty-four hours afterward he found the uterine cavity occupied by the fœtal mass, while the tumour which had

previously existed above the uterus had entirely disappeared. In this instance bi-manual examination was unusually easy, and there could be no doubt whatever of this latter fact.

It seemed to him that Dr. Rockwell was correct in his view that the galvanic was to be preferred to the faradic current in these cases. There were two reasons that occurred to him why the galvanic was preferable. First, the faradic current had the effect of causing a contraction of the muscular fibres of the tube, and, secondly, while the faradic current might kill the fœtus by the shock it produced, the galvanic had the additional advantage of decomposing the amniotic fluid.

In Dr. McBurney's case Dr. Emmet had made a suggestion, which he thought might prove of service in a certain proportion of instances. "Why not dilate the uterine cavity," said he, "and extract the fœtus in this way?" This might, perhaps, be a bold and difficult procedure, but, in the hands of an operator as skilful as Dr. Emmet, could no doubt be successfully accomplished in some cases of tubal or interstitial pregnancy. When rupture of the tube had taken place, he believed it to be quite justifiable to perform laparotomy, as proposed by Kiwisch, and, with all the resources of modern surgery now at one's command, he thought that the prospect of success would be as good as in many bad cases of ovariotomy.

In concluding the discussion, Dr. LUSK remarked that the galvanic current had been proposed in the treatment of extra-uterine pregnancy as early as 1857. At first its introduction in this field of surgery was hailed with great enthusiasm, but afterwards the plan was abandoned because the operators found that they did not obtain as good results from it as from simple puncture of the sac. It was after the use of the galvanic current had been given up that Dr. Allen resorted to the faradic current, and up to the present time (as he had mentioned in the paper) nine cases had been reported in which it had been successfully employed without the occurrence of a single bad symptom. Or, leaving out Dr. McBurney's case, in which he had been under the impression that the faradic current had been used, until corrected by Dr. Rockwell, this evening, there would be eight successful cases on record.—*Boston Medical and Surgical Journal*, March 17, 1881.

—

On the Determination of the Indications for Gastrotomy in Cases of Extra-Uterine Fœtation.

Dr. C. LITZMANN, in a paper on this subject (*Archiv für Gynäkalogie*, Bd. xvi. p. 323), grounds his observations on two cases of the kind on which he operated on successive days, and on an analysis of forty-three cases extracted from various sources.

The cases were: I. Mrs. P., a healthy, well-built woman, aged 25, pregnant for the second time. After her first confinement she had a pelvic inflammatory attack. She came under observation in the ninth month, and had had during the whole pregnancy repeated attacks of abdominal pain, and twice in the early months hemorrhage from the vagina. The urine contained albumen. Passing from the right side of the abdomen above, to the left side of the pelvis below was a large, oval, completely-fixed tumour, over which the abdominal wall was partially movable, and in which, at its upper part could be felt a child's head. To the left, and about the height of the umbilicus, could be felt the enlarged uterus, which was slightly movable on the mass. The heart-sounds were audible on the right side and high up. Per vaginam, the lower part of the swelling could be felt projecting into the roof; to the right side and to the left, and higher up, lay the os uteri. The uterus was movable, the swelling was not. A right

tubo-uterine pregnancy was diagnosed. Gastrotomy, with antiseptic precautions, was performed, and the placenta was not interfered with. There was only slight bleeding. The child weighed five and a half pounds, was greatly deformed from pressure, and died almost immediately. There was hardly any liquor amnii. A drainage-tube was passed into the cavity, through which it was washed out once or twice daily with carbolic water. On the thirteenth day this washing out caused profuse hemorrhage, which was stopped by compression. Two similar bleedings occurred on the two subsequent days. On the seventeenth day the placenta was removed without much hemorrhage taking place, and on the eighteenth the patient died. The pregnancy was found to be tubal, not interstitial.

Case II., aged 35, pregnant for the seventh time; presented the ordinary history of extra-uterine pregnancy. On examination, the apparently empty uterus was felt pressed backwards by a large, round, fluctuating tumour, in which could be felt the small parts of a child, and over which could be heard the fœtal heart. At the end of the thirty-second week the fœtal movements ceased to be felt, and at the same time the heart-sounds became inaudible. Five days afterwards the breasts swelled, and a mass, probably decidual, was expelled from the vagina. A fortnight later small quantities of very fetid matter came away from the vagina in gushes. Menstruation came on seventeen days after the death of the child. Nine weeks later gastrotomy was performed, and the fœtus removed, along with the placenta and the greater part of the membranes. Though the placenta was cut into by the incision, there was no serious bleeding. The operation was conducted antiseptically, and recovery was uninterrupted.

After contrasting these two cases, the author reproduces from various sources, German, American, and English, accounts of forty-three cases of extra-uterine pregnancy where gastrotomy was performed, and divides them into cases operated on during the life of the child, and cases operated on after its death. He, however, excludes from the reckoning all those cases where a single abdominal incision was made to evacuate an abscess which had formed in the sac. In ten cases of the former class there were nine deaths and one recovery, while in thirty-three of the latter the deaths were fourteen and the recoveries nineteen. After a full analysis of these cases he comes to the conclusion that the dangers of hemorrhage, either during the operation or on the subsequent separation of the placenta, are, in general, too great to warrant gastrotomy during the life of the child, which, moreover, in consequence of compression within its sac, is usually so much deformed and so imperfectly developed as to be unable to live. Accordingly, except in those cases in which the size of the sac and of the living fœtus contained in it are such as render it nearly certain that the child is large, well-formed, and likely to be viable, Litzmann maintains that the proper course is to wait for a sufficient length of time after its death to allow of complete thrombosis and obliteration of the placental circulation before interfering. He does not attempt to define the period necessary to wait until the circulation is closed, but thinks it ought to be a good few weeks. In his own case the operation was performed eleven weeks after the death of the child.—*Edinburgh Med. Journal*, Jan. 1881.

—

Vesico-Vaginal Fistula treated by the formation of a Recto-Vaginal Fistula and Closure of the Vagina.

Complete occlusion of the vagina has long been looked upon as the *dernier ressort* in cases of vesico-vaginal fistula in which, either from their size, or the unhealthiness of the tissues bounding them, restoration of the vaginal wall to its integrity

seemed hopeless. But the data from which to judge as to the effect of the urin upon parts not adapted to contain it, and as to what is the way to get the be artificial reservoir, are as yet scanty. A case by Dr. GEZA ANTAL, publishe in the *Archiv fur Gynäkologie*, gives us some information on this head. H case was one in which the loss of tissue was so great that closure of the fistul was thought out of the question. His first thought was to close the vagina in i lower third, letting the urine and menstrual fluid be passed per urethram. Bu repeated operations for this purpose all ended in failure. Then it occurred t him to unite the labia, first making a recto-vaginal fistula; thus making th rectum a common cloaca, and trusting to the rectal sphincter to retain both kin of excreta. This he did. While the patient was under surgical treatment, th bladder was washed out with ½ per cent. solution of carbolic acid. The operatio was successful. The result has been that the patient now passes urine per re tum at intervals of from two to two and a half hours. During these intervals sh does not complain of any discomfort. Menstruation is regular, the bloo escaping without hindrance. Several months after the operation no chan could be discovered with the speculum in the rectal mucous membrane. Th favourable results above described had lasted, when the author wrote, for seve months after the operation.—*Med. Times and Gaz.*, March 12, 1881.

—

Extirpation of Uterus and Ovaries.

At a late meeting of the Obstetrical Society of London Dr. THOMAS CHAMBE (*Lancet*, Feb. 5, 1881), read a paper on "Complete Extirpation of the Uter with both Ovaries, weighing ten pounds; recovery." Jane S——, aged fort three, was admitted into the Chelsea Hospital for Women on May 24th, 188 In 1870 she first noticed a lump in her right groin, which grew slowly for fi years. After this menorrhagia commenced, and gradually increased. Pain a hemorrhage were excessive, and she eventually became too weak to attend as out-patient, and was remarkably emaciated. The tumour was freely movab from side to side, and was very soft and doughy, but without fluctuation. Th pelvic cavity was unoccupied, the vagina drawn up into a cone, with the os a cervix, both small, in the centre. There was a periodical discharge of wate fluid through the vagina. Hence a diagnosis of fibro-cystic tumour was mad Medical treatment having proved of no avail, extirpation of the uterus was pr posed to the patient, and she decided in favour of the operation. It was pe formed on June 2d. The abdominal incision was extended to eleven inche The broad ligaments were tied with silk at each side, a parallel clamp plac above the ligatures, and the uterus cut away. After a few minutes arterial hemo rhage occurred from a large vessel, which was at once secured. The cervix w then transfixed by a double ligature, the clamp removed, the ligatures tightene and the stumps replaced. By the twenty-first day the patient was convalescen a free discharge of offensive matter from the vagina having taken place sudden on the fourteenth day. The tumour proved to be a lobulated white fibroid, n fibro-cystic, and contained very large vessels.

Dr. HEYWOOD SMITH thought that the term hysterectomy should be limit to amputation of the uterus. He considered cöphorectomy safer than removal the uterus when life was threatened by flooding and pain.

Dr. ROUTH had some years ago tabulated a number of fibro-cystic tumours compared with pure fibroids of the uterus, and had found that in fibro-cystic di ease menorrhagia was rare.

The Therapeutics of Ovarian Compression.

M. BOURNEVILLE (*Le Progrès Médical*, No. 2, 1881) records the following case. He was called to see a young married lady, aged 22, who had suffered from hysteria for some years, but latterly the attack had been of daily occurrence. After one of these, which occurred on December 21, she became paralyzed on the right side, with hemianæsthesia of the same side. During the night of the 30th, spasmodic contraction of the lower jaw supervened. On December 31st, M. Bourneville found the following symptoms: Right hemiplegia and hemianæsthesia, with stiffness of the joint; double ovarian hyperæsthesia; contraction of the jaw. After practising ovarian compression for some minutes, the spasm of the jaw relaxed, and the patient could put out her tongue; but, when the compression ceased, the spasm reappeared. After a short interval, he again compressed the right ovarian region, with a similar result; and, when compelled to desist, from fatigue, he discovered that the spasm of the jaw did not recur, that sensibility returned to the right side, and that the patient could move her right arm and leg. A further compression resulted in the complete disappearance of all the symptoms, so that the patient got up and walked. M. Bourneville remarks that such astonishing results may be obtained, if the medical attendant will employ ovarian compression for a sufficient length of time, and repeat it frequently at short intervals.—*British Medical Journal*, March 5, 1881.

Medical Jurisprudence and Toxicology.

Poisoning by Atropia successfully treated by Hypodermic Injection of Pilocarpin.

Professor PURJESZ relates in the *Pester Med.-Chir. Presse*, Nos. 15, 17, and 18, 1880, the case of a hospital patient, aged 19, under treatment for aortic insufficiency and keratoiritis, who drank with suicidal intent the contents of a bottle of solution of atropin which was used for dropping in his eye. The quantity of atropin taken was about nine-tenths of a grain. The pupils were dilated to the maximum, the face was pale; respirations frequent, 40 to 50 in the minute; pulse 140 to 150. The patient was perfectly unconscious; sensibility was not lost. Relying on the observation by Luchsinger of the physiological antagonism between atropin and pilocarpin, Dr. Purjesz injected in succession six syringefuls of a one per cent. solution of pilocarpin (about 0.9 grain in each); and repeated the injection at intervals from five to eight minutes. After the tenth injection, the patient began to speak; the pupils were distinctly narrower; and, as the secretion of saliva and sweat had not yet appeared, another injection of nine-tenths of a grain of pilocarpin was made. After this dose, the patient gave rational answers; the pulse fell to 80; the pupils regained their normal size, but reacted rather slowly to light; the respiratory movements became normal, the skin moist, and all the symptoms of poisoning by atropin disappeared.—*British Med. Journal*, Feb. 26, 1881.

Localization of Strychnia.

Husemann, Dragendorff, and other chemists have advised, in cases of poisoning, that chemists in looking for strychnia should especially direct their researches to the liver. Dragendorff alleges that he has never been able to isolate the alkaloid

from the brain, even when the whole organ has been used for the chemical examination. He further states that Gay has isolated strychnia from some special parts of the nervous system, as for example, the medulla oblongata, and the pons Varolii, and that he has himself succeeded in extracting it from the medulla oblongata in cases of poisoning. LAJOUX and GRANDRAL have published their results from analysis of the brain of a person who died from the effects of 2.33 grammes of tincture of nux vomica, corresponding to only 0.0036 gramme (.0525 grain) of strychnia. Three-fourths of this were employed subcutaneously and the rest was administered by the mouth. Although the quantity was very small, yet strychnia was found throughout the brain, and gave its characteristic reaction. If this observation be correct, chemists will do well to examine the brain in cases of suspected strychnia poisoning, as well as the other organs.—*British Med. Journal*, Feb. 12, 1881.

—

Poisoning by Glycine.

Dr. LÉONFFRE, Physician of the Orphan Asylum at Rocca, relates in the *Lyon Médical* cases of poisoning which he has observed in several orphans of the institution. These young children had been chewing fragments of roots of glycin instead of Spanish liquorice. At the outset, they complained of a gastralgic pain the face became congested, and the cheeks reddened; but this reddening was very transient, and gave way to paleness as soon as the children felt nauseated. A few minutes afterwards, vomiting commenced, consisting first of alimentary matters then of bile and mucus. The patients then complained of a great feeling of uneasiness; the face was pale and pinched; the eyes sunken, and surrounded by blue lines; the pupils were largely dilated; the skin, and especially the extremities, cold; muscular weakness was very marked; and the patients complained of feeling their legs bend under them. Among those who were most ill, an irresistible tendency to sleep was observed. The children complained of chill; the pulse remained at 80, very weak; and in two cases the voice was imperceptible. The capillary circulation was defective; and in two patients, whose pulse was hardly perceptible, the extremities were reddened, and the face, as well as the skin of the trunk, marbled with blue lines. The respiration was normal, and rather slackened than obstructed. There was neither delirium nor convulsion. The intellectual faculties were intact, except for the torpor. The secretions were not disturbed, the skin not presenting that appearance of sweating which is met with in analogous conditions. The action of the glycine on the intestinal tube was not marked in any of the eighteen cases, except in one girl, who was purged eleven times. The accidents observed were rapidly counteracted by the administration of hot tea and coffee, and the application of hot water bottles. In one case only, energetic friction was necessary to combat collapse and the tendency to sleep. Dilatation of the pupil was the earliest and most constant of all the symptoms. The quantity of glycine chewed by each child must have varied from one to six *grammes* (fifteen to ninety grains). Thus it seems that glycine possesses marked toxic properties, and that it acts like tobacco. This action of glycine was unknown to Dr. Léonffre, and he has not found it mentioned anywhere.—*British Med. Journal*, Jan. 1, 1881.

MEDICAL NEWS.

Impure Ice as a Cause of Intestinal Disease.

That period of the year, when ice (which is now used by all classes to an extent entitling it to rank as a *necessity* instead of, as formerly, a *luxury* of life) is employed in various beverages to the amount of millions of pounds, cannot delay much longer, so that a few words of caution in regard to the purity of this article will be seasonable.

It is popularly believed that water frees itself from dangerous organic matter, as it does from some saline contaminations, during the process of freezing, and also that the vegetable or animal germs of typhoid and other zymotic fevers are killed, or at least sterilized by congelation of water in which they exist. Both of these ideas, however, are unquestionably erroneous, as has been repeatedly proved by various experiments which ignorant hotel-keepers try, without the least intending it, upon their guests on a scale which would make the boldest vivisector stand aghast before the suffering inflicted, even if it were only upon the brutes which form the subjects of his researches.

Such was notably the case in an epidemic of intestinal disorder which occurred at Rye Beach, N. H., a few years since, of which an excellent account was published in the Report of the Massachusetts Health Board for 1876, by Dr. A. H. Nichols, who attended most of the persons suffering from the malady. It appears that early in the season a mild form of gastro-intestinal disturbance made its appearance among the guests of a particular hotel at this watering-place. The symptoms were, in general, giddiness, nausea, or vomiting, diarrhœa, and severe abdominal pain, accompanied by fever, loss of appetite, and mental depression. The disorder was at first attributed to the well-water of the place, which is strongly impregnated with sulphate and carbonate of lime and magnesia, but the peculiar grouping of the patients almost exclusively among the sojourners at a single hotel, accommodating about three hundred, whilst occupants of another hotel and of neighbouring cottages, to the number of about seven hundred persons, were free from illness, strongly indicated some specific local origin. The well-water was almost immediately suspected of sewage contamination, but, on inquiry, it was found that the wells were all sunk in an elevated ridge safely removed from drains, cesspools, and other sources of pollution. Moreover, it was also ascertained that in some cases the individuals affected, being suspicious of the water, had limited themselves to other beverages; but, as afterwards transpired, had not hesitated

to use ice, either melted or otherwise. The drainage system of the estab lishment, which had recently been put in complete order, was found almo faultless, and the milk-supply of unquestionable purity; but, on the atte tion of the examining physician being directed to the stock of ice used i the hotel, conclusive proof of its dangerous quality was promptly obtaine A resident of the place stated that, on testing a portion of the ice the pr vious winter, he had experienced nausea and distress for the remainder the day. Two gentlemen having taken a quantity of ice with them upo an excursion, during which they drank the water formed from it, we made violently ill. Both the house in which the ice was stored and th water from the melted ice gave off a decidedly disagreeable, or even offe sive, odour. Finally, a visit to the pond from which the ice had been gath ered disclosed the fact that much of its water was dark-coloured, foul, an highly contaminated with filthy marsh mud and decomposing sawdus Chemical analyses showed that both it and the suspected ice contained large excess of organic and volatile impurities, including .04 of a grai per gallon of albuminoid ammonia. The crucial test, however, of inju rious quality pertaining to this ice was afforded by its disuse in the hote coincident with which was noticed an abrupt amelioration of the symp toms in all who had previously been ill, and the entire absence, so far known, of any new cases. The ice was partaken of during a period six weeks by about five hundred persons. Of these, the majority escape without injury; a large number suffered slight or temporary attacks of il ness; and twenty-six adults manifested grave, continued, and characte istic symptoms.

The Connecticut State Board of Health (Report for 1879) informs u that, in several instances, attention has been drawn to sewage-contam nated ponds with ice-houses upon their borders, and that several isolate cases of enteric disease, and one death, from the free use of ice polluted b sewage, have been recorded in that State during the year.

The curious natural experiment of the United States vessel "Plymouth," an elaborate report of which was reviewed in the *American Journal o the Medical Sciences* for Jan. 1881, shows conclusively that the germs o yellow fever are not infallibly destroyed by a freezing, probably not by zero temperature. Without venturing on any of the unsound reasonin from analogy, too common among medical theorists, this fact alone is suf ficient to warn us of the possible danger that the poisons of enteric feve and other zymotic affections are not destroyed by the congelation of th water in which they float, even without the direct and positive testimon such as that given above that impure ice, especially when gathered from ponds polluted by sewage, may constitute a prolific cause of disease.

Resection of the Stomach.—The health of the patient on whom Professor BILLROTH performed the operation of removal of a carcinomatous portion of the stomach (see last number of *Medical News and Abstract*, page 232), is satisfactory. The wound is perfectly healed, and the sutures were removed at the end of last week. The patient takes milk and wine, only complaining of constipation, which is relieved by enemata, and of a bedsore on the sacrum, which was caused by her depressed condition. All experiments with semifluid food have failed, and the nourishment has been confined to milk.—*British Medical Journal*, March 5, 1881.

Under date of April 2, we learn that the patient has returned home apparently well, and able to take solid food. Dr. Billroth has since performed the operation twice. The second patient survived eight days. The third, on whom he operated on the 12th of March, for a considerable cancerous tumour, died in twelve hours. The facility of the operation, the absence of peritoneal reaction, and the holding power of the sutures, were apparent in all the three cases.

—

Health of New York.—Smallpox has increased considerably during March, the number of cases being more than double that reported for February. Scarlet fever and diphtheria have decreased, while typhoid fever and measles have increased. Considerable alarm has been created by the appearance of typhus fever, which has not prevailed in the city for a number of years. The first cases were found in a densely crowded lodging-house, at the corner of Prince and Marion Streets, where four hundred lodgers were nightly sheltered. These cases were at once removed to special pavilions on Blackwell's Island, and the premises thoroughly disinfected by the Health Board. During the first week of the endemic 41 cases were reported. During the second week only 5 cases were discovered, but the number rose to 45 in the third week (ending April 10). The type of the disease has been comparatively mild, although many cases have terminated fatally. On April 4th there were 99 cases of variola and 51 of typhus at the Riverside Hospital. On April 14th there were 119 of variola and 90 of typhus fever.

The medical profession of New York has shared the lively and unabated popular interest on the subject of street cleaning. The April number of the *Medical News and Abstract* contained the resolutions adopted by the Academy of Medicine having reference to the causes for the present increased malignity of disease, and the alarmingly high rate of mortality in the city. These resolutions were presented to the Citizens' mass-meeting held on March 18th. A committee of twenty-one, appointed at that meeting, to devise measures for securing a rapid and thorough cleansing of the streets, prepared and presented to the Legislature a bill removing control of the Street Cleaning Bureau from the Police Board and conferring it upon the Mayor, with power to nominate a superintendent of the work. The bill was passed by the Senate on March 30, but rejected on April 8 by the Assembly, which body adopted a substitute, intended to reserve the patronage to the dominant party, giving the Board of Health power to confirm the Mayor's nominee for superintendent. A second indignation mass-meeting was held April 12, and resolutions condemning the action of the Assembly in rejecting the bill of the committee of twenty-one, and urging its immediate reconsideration and adoption, were unanimously passed. A large and enthusiastic mass-meeting of physicians in favour of the Citizens' street cleaning bill was also held on April 13, at Chickering Hall. Dr. Willard Parker presided, and addresses were delivered by Drs. Barker, Dalton, Sayre, Loomis, and other eminent medical men. Resolutions were adopted protesting against the rejection of the Citizens' bill by the Assembly, and demanding that the representatives of

the city in the Assembly reverse their action, and endeavour to secure the passage of the bill. A committee of five were appointed to present the resolutions to the Governor of the State, the President of the Senate, and the Speaker of the Assembly.

—

Medical Experts.—A trial took place recently in the Common Pleas Court of Montgomery County, Ohio, which afforded an incident of some interest to the profession. It was a suit for damages alleged to have been inflicted by one woman on another while scuffling in a playful way. Expert testimony was called as to injuries to the shoulder-joint and arm, and it was proposed that a personal examination be made of the plaintiff and an opinion given as to the condition of the parts. Dr. Reeve, of Dayton, being on the stand, demurred to this and appealed to the Court, urging the injustice of a medical witness being compelled to make such an examination without compensation, and declining to make it unless under direct order of the Court. Judge Elliott in reply fully and freely recognized the fact, that a professional man's education was his capital and ought not to be called upon without recompense. The attorneys also openly deplored the injustice of the law in such cases, and admitted that a reform was much needed. Finally, the party interested agreed to pay a fee, and the trial proceeded.

There is no doubt that Dr. Reeve's example might often be followed to advantage. The Courts would, we believe, generally recognize the injustice of the proceeding, and one so widely different from that pursued toward lawyers in similar circumstances, as was pertinently urged by Dr. Reeve.—*Cincinnati Lancet and Clinic*, March 12, 1881.

—

Revision of the German Pharmacopœia.—The revision of the German Pharmacopœia began on October 15th, on which day the commission appointed for the purpose commenced a series of sittings, presided over by Dr. STRUCK, for the purpose of making preliminary arrangements, and concluded their work on the 25th of the same month. A further meeting of the committee will be held, probably next Easter, for the final revision of the text; meantime the editing is entrusted to the chemists and pharmaceutists of the commission, with the addition, as medical experts, of Professors Ziemssen, Gerhardt, and Eulenberg. The composition of the commission is very comprehensive, and is considered in Germany to be very happy, including the representatives of all those who are interested in the work—physicians, public medical officers, clinicists, pharmacologists, chemists, and apothecaries. We quote it here because it is interesting as compared with that of the British Pharmacopœia Committee. The new pharmacopœia, unlike the old Prussian, Austrian, and Swiss Pharmacopœias, will be published in the German language, including the heading of each article, to which, however, the Latin titles will be added. The title of the new edition will be *Arzneibuch des Deutschen Reiches*. Only two voices were raised, it is said, against this resolution; those, it is believed, of Flükiger and Poleck, who considered it might be inconvenient not to have the pharmacopœia in the international Latin tongue, especially in reference to the possibly approaching international pharmacopœia. This was overruled, however, on the ground that such an international pharmacopœia is still far distant; and that, even if it should be published, it will certainly very rapidly be translated into the language of each country; just as all Latin pharmacopœias have always had alongside of them translated pharmacopœias of much greater popularity. The commission has treated the question of striking out unnecessary drugs and preparations in a

very radical fashion. It is said that, of 797 articles in the German Pharmacopœia, no fewer than 370—that is to say, nearly a half—are eliminated by this commission. Among them are acetum colchici, aconitin, ammonium carbonicum, pyro-oleosum, valerianates of bismuth and of quinine, bromine, prepared shells, elemi, dry and inspissated ox-gall, several preparations of iron, kino, logwood, mastich, acetate of morphia, santonate of soda, oxymel of colchicum and of squills, guaiacum and scammony resins, lactate and valerianate of zinc, etc.; as well as about half of the hitherto officinal distilled waters, plasters, extracts, ethereal oils, tinctures, and ointments. They are proceeding much more cautiously in adding new agents to the pharmacopœia. They have added salicylic acid, nitrite of amyl, apomorphin, physostigmin, jaborandi, and pilocarpin; on the other hand, they have rejected condurango, coto bark, quebracho bark, leaves of eucalyptus and the preparations thereof, araroba and chrysophanic acid, butyl-chloral, bromide of camphor, gelsemium, etc. In the matter of antiseptic dressing, materials have been added, as concentrated carbolic solution, and carbolic water prescriptions formulated for absorbent cotton-wool; catgut in three strengths, gutta-percha paper, thymol, and acetate of alumina. The constitution of this committee appears to have enabled it to set to work with great vigour, and get through it with rapidity.—*British Medical Journal*, Jan. 15, 1881.

—

The Medical Law of New York.—The Act of 1880 provides that no person shall "practise physic or surgery within the State unless he is twenty-one years of age, and either has been heretofore authorized so to do pursuant to the laws in force at the time of his authorization, or is hereafter authorized so to do," either by a license from the regents of the University of the State of New York, a diploma of an incorporated medical college within the State, or a diploma of a similar institution without the State, provided it be endorsed as approved by some proper medical faculty of the State. But every physician and surgeon, with the exception of practitioners of ten years' standing and a few others, must register in the office of the clerk of the county where he is practising, or, if hereafter authorized, intends to practise, his name, residence, place of birth, together with his authority to practise, to all of which he must subscribe. He also must make affidavit as to the manner of his license or authority, the date of the same and by whom granted, which, if wilfully false, shall subject the affiant to conviction and punishment for perjury. Any one who violates either of these provisions or the one in regard to practising, or who shall practise under cover of a diploma illegally obtained, shall be deemed to be guilty of a misdemeanor, and on conviction shall be fined not less than fifty dollars nor more than two hundred dollars for the first offence, and for a subsequent offence he shall be fined not less than one hundred dollars nor more than five hundred dollars, or imprisoned not less than thirty days, or both.—*Popular Science Monthly*, April, 1881.

—

Cremation in the United States.—According to the *Popular Science Monthly*, April, 1881, steps have been taken in New York to provide the necessary organizations to furnish facilities for cremation. A draft of a charter has been approved by the persons concerned in the movement, for the formation of "the United States Cremation Company (limited)," with a capital of fifty thousand dollars, whose peculiar object shall be "to cremate the human dead in the quickest, best, and most economical manner." A plan has also been adopted for the formation of the "New York Cremation Society," as an association distinct from the purely business enterprise, having for its object "to disseminate sound

and enlightened views respecting incineration as preferable to burial, and to advance the public good by offering facilities for cremation."

—

Fracture of both Clavicles Simultaneously.—In the *Gazzetta Med. Lombardia*, Jan. 8, an abstract is given of a case in which both clavicles were simultaneously fractured—this being so rare an occurrence that Malgaigne only met with it once in 2358 cases of fracture of the clavicle; and Gurlt, in his great work on Fractures, states that he has only been able to meet with fifteen recorded cases. Sayre's apparatus was employed, and the patient was perfectly cured in thirty days, no trace of deformity being visible.—*Med. Times and Gazette*, Jan. 29, 1881.

—

The Columbian Institute.—A medical institution called the Columbian Institute has been recently incorporated in New York City. The object of the institute is to provide an establishment at which patients may, if they desire, be treated by their own physicians. The institute will chiefly devote itself to the treatment of chronic diseases.

—

Training Schools for Nurses.—A training school for nurses has been established in connection with the Brooklyn City Hospital. It is conducted upon the same plan as the New York training school connected with Bellevue Hospital. The report of the latter school for 1880 states that sixty-three nurses are now in the institution. The school has been in operation since 1873, and has graduated one hundred and twenty nurses. The demand for training school nurses in private families far exceeds the supply. Two graduates are about to establish a training school in connection with the Cook County Hospital, Chicago.

—

Inspection of Plumbing.—A bill requiring the plumbers of New York and Brooklyn to register their names, and giving the Board of Health supervision over all new plumbing has been presented to the New York Legislature. The bill was framed by the Society for Sanitary Reform.

—

International Medical Congress, London, 1881.—The following subjects are proposed for discussion in Section III. (*Pathology and Morbid Anatomy*): 1. The relations of minute organisms to certain specific diseases, such as relapsing fever, ague, and malignant pustule [anthrax]. 2. The relations of minute organisms to unhealthy processes arising in wounds, and to inflammation in general. 3. Tubercle: (*a*) Its histological characters. (*b*) Its relation to inflammatory processes in different organs, such as the lungs, lymphatic glands, bones, and joints. 4. The origin of cancer and sarcoma, and their relation to the normal tissues in which they arise. 5. Diseases of the kidneys: (*a*) The morbid histology of the different forms of Bright's disease. (*b*) The relation of renal disease to disturbances of the general circulation, and to alterations in the heart and bloodvessels. 6. Recent researches in the morbid anatomy of the brain and spinal cord.

For the pleasure of the members of the Congress the Reception Committee are arranging a series of entertainments and excursions during the week of the Congress, of a most attractive character. On Tuesday, Aug. 2d, an informal reception will be held in the afternoon, at the Royal College of Physicians, which occasion, it is thought, will afford an excellent opportunity for introductions. On

the evening of Wednesday, the English members will entertain their foreign *confrères* at a *conversazione* at the South Kensington Museum. Entertainments will also be given on Thursday and Friday; but up to this time their nature has not been definitely fixed upon. On Saturday, August 6th, there will be no business meetings later than 1 P. M.; and excursions will be made to various places of interest in the neighbourhood of London. On this day the Harvey Memorial Committee purpose that the statue of Harvey shall be unveiled at Folkestone. A special train by the Southeastern Railway will take between one and two hundred members of the Congress, with other distinguished persons, to Folkestone, free of cost, where they will be received by a deputation of local magnates, and conducted to the statue which will be unveiled. After the completion of the ceremony, the mayor and corporation will entertain their visitors at a banquet in the town-hall. This visit will afford an excellent opportunity of seeing an English watering-place at its best. On the same day, a charming excursion has been planned by Dr. Langdon Down, who has generously invited five hundred members of the Congress to a garden party at Normansfield, Hampton Wick. Dr. Down will meet his visitors at Teddington station, and will guide them through Bushy Park to Hampton Court Palace. The party will then proceed by water to Normansfield, where a select party of Dr Down's friends will meet them. On the same day Sir Joseph Hooker will receive a number of members at Kew Gardens. On Sunday special services will be held in St. Paul's Cathedral and Westminster Abbey, at which Canon Liddon and Dean Stanley will respectively officiate. The Royal College of Surgeons has signified its intention of entertaining the *Congress* at a *conversazione*.

A temporary museum will be opened during the sessions of the Congress in the rooms of the Geological Society for the exhibition of living examples of certain rare diseases, microscopic specimens, and objects of novelty or rarity having reference to the processes of disease or the results of injury.

—

Prescribing over the Counter.—The Medical Association of the District of Columbia held a meeting April 5th to consider the question of certain abuses by druggists in prescribing over the counter, and in the unwarrantable renewal of prescriptions. They adopted the following resolutions:—

Whereas, It has come to the knowledge of the Medical Association of the District of Columbia, through information of several of its members, that a number of druggists of this city are in the habit of prescribing for and taking charge of cases of sickness; and

Whereas, The diagnosis and treatment of disease belongs to the province of a distinct profession, and as a pharmaceutical education does not qualify the pharmacist for these responsible offices, and

Whereas, The renewal of certain prescriptions merely at the request of the patient or other person who may be ignorant of the evil results attending the continued use of a medicine ordered for the occasion only, may work serious injury to the patient, therefore be it

Resolved, That the public welfare, as well as the best interests of both the profession of medicine and that of pharmacy, are opposed to druggists usurping the functions of the physician by prescribing or giving medical advice.

Resolved, That when the physician shall consider it desirable that a prescription should not be renewed, he will write on it "not to be renewed," and that prescriptions so marked should not be renewed by the pharmacist without order of the profession.

Resolved, That members of this Association will withhold their support and patronage from such druggists as thus fail in their duty to their own profession, or disregard the directions of the physicians in reference to renewals.

Resolved, That the interests of the medical profession are safe in the hands of reputable pharmacists, who govern themselves according to the code of ethics of the College of Pharmacy of the District of Columbia.

Resolved, That professional courtesy between physicians and pharmacists, demands that a due regard be shown towards each other in all matters pertaining to prescriptions, that neither may be unduly reflected upon nor compromised.

—

A Triumph of Dentistry.—At the last meeting of the Medical Society at Strasburg, reported in the *Medical Gazette* of Strasburg, Dr. JULES BŒCKEL presented, in the name of M. Sauval, dentist, a lady for whom the latter had extracted a small molar tooth for dental caries, with violent pain; and, having found it slightly carious to the bottom of its root, he sawed off the points of the root, filled it with gold carefully throughout the carious channel, and then reimplanted the tooth. The lady was free from all her pain; the tooth re-established itself solidly in the mouth; and, at the date at which she appeared at the Society (three weeks after the operation), the tooth served for mastication as well as her other teeth. This is certainly a remarkable example of what is technically described as dental autoprothesis with aurification.—*British Medical Journal*, Jan. 29, 1881.

—

Endowment of Presbyterian Hospital, New York.—An effort is being made by the officers of the Presbyterian Hospital, N. Y., to secure an endowment fund for that institution. One of the directors has promised to give $60,000, provided $100,000 be contributed by others.

—

A Swindler preying upon the Doctors.—An impostor personating Dr. Geddings, of Charleston, S. C., has recently swindled a number of the leading physicians of New York. He states that his funds have been exhausted, and he has obtained considerable sums from his victims for the ostensible purpose of returning home.

—

Graduates in Medicine in 1881 (*continued from p.* 248).

Columbus (O.) Medical College,	63
Cleveland Medical College,	51
Starling Medical College (Columbus, O.),	36
Missouri Medical College (St. Louis),	119
St. Louis Medical College,	43
College of Physicians and Surgeons (St. Joseph, Mo.),	14
Detroit Medical College,	27
Memphis Hospital Medical College,	18
Chicago Medical College,	45
Albany Medical College,	58
Columbian University (Washington, D. C.),	5
University of Georgetown (D. C.),	5

We are requested to state that in addition to the 110 graduates at the March commencement of the University of Pennsylvania, there were 5 graduates at the preceding commencement in June, making a total for the year of 115.

The New York Smells.—The Committee of the State Board of Health has, during the past month, prosecuted its investigations into the source of the offensive odours emanating from Hunter's Point, Brooklyn, and has visited the factories suspected of producing the odours. A bill has been prepared which provides for the abolishment of the Hunter's Point nuisances.

—

Sanitary Convention.—A very successful Sanitary Convention was held at Battle Creek, Mich., March 29 and 30, under the auspices of the State Board of Health. A number of excellent papers were read, and there was an instructive exhibition of sanitary apparatus and appliances.

—

Scarlet Fever in Charleston, S. C.—For some weeks a serious type of scarlet fever has prevailed among the children of Charleston. During March there were twenty deaths. The first case was reported on the 1st of January, and the first death occurred on the 1st of March. The death rate has increased, and there has been no diminution in the number of cases. It is estimated that there have been nearly two hundred cases. In some instances the attacks have been very severe, and in one case death resulted in sixteen hours after the first symptoms of the disease appeared.

The fever has so far been mostly confined to the white children, not more than one case in ten of the whole number reported having occurred among the coloured people.

—

A Congress of Laryngology is announced for September, 1882, in Paris. The members of the organizing committee are MM. Fournier, Gouguenheim, and Krishaber.

—

Influence of the Antiseptic Method on Medical Jurisprudence.—In a lecture at the close of his last session, Professor NUSSBAUM (*Wiener Medic. Presse*, Nos. 21–23, 1880), discusses the consequences following to medical jurisprudence from the revolution in surgical opinion caused by the antiseptic method. So strong an adherent is he of this method, that he would extend the statute of the German penal code, dealing with bodily injuries and damage to health through negligence or malapraxis, to such a case as a surgeon examining a wound with a finger not disinfected according to the strictest antiseptic principles. He considers, also, that the duty of carrying out these principles excuses the medical man from making, in a medico-legal case, that thorough and searching examination of a wound formerly required.—*British Medical Journal*, Jan. 8, 1881.

—

Sea-side Nursery.—St. John's Guild, of New York, is about to erect a sea-side nursery at Cedar Grove, Staten Island. The object of the nursery is to receive from the Floating Hospital of the Guild such children as are in need of a prolonged sojourn in the bracing sea air. The nursery will be ready for occupation in June.

—

Private Gynæcological Hospital.—Dr. T. GAILLARD THOMAS, of New York, has recently built a private hospital, for the treatment of women's diseases, at the corner of Lexington Avenue and Fifty-second Street, New York. The resident physician is Dr. Jas. B. Hunter.

Physicians' Mutual Aid Association of New York.—The twelfth annua report of the Board of Directors of the New York Physicians' Mutual Aid As sociation states that the Society is prospering. The funds have been increase from $3000 to about $6000. The number of members is 350.

—

Kentucky State Medical Society.—This society met in twenty-sixth annual ses sion at Covington, on April 5, 6, and 7. Dr. L. B. Todd, of Lexington, Presi dent in the chair. A number of papers were read. The following officers wer elected for the ensuing year. President, J. W. Holland, M.D., of Louisville Vice-Presidents, Drs. Charles Munn, of Nicholasville, and C. H. Thomas, o Covington; Secretary, Dr. L. S. McMurtrie, of Danville. The next meetin will be held at Louisville, on the first Wednesday in April, 1882.

—

University of Pennsylvania.—Dr. Charles K. Mills has been appointed Le turer on Mental Diseases. This course of lectures will be supplemented by clin cal instruction at the Philadelphia Hospital, the Pennsylvania Training Institu tution for Feeble-Minded Children, and the State Hospital for the Insane Norristown.

—

University of Maryland.—Professor L. McLane Tiffany has been elect to the chair of Surgery in this institution, rendered vacant by the resignation Prof. Christopher Johnston. Dr. I. E. Atkinson has also been elected Profe sor of Pathology and Clinical Professor of Dermatology.

—

Munificent Gifts.—Col. Thomas A. Scott, of this city, has given $50,000 the Jefferson Medical College, $50,000 to the University of Pennsylvania, an $30,000 to the Philadelphia Orthopædic Hospital and Infirmary for Nervou Diseases. The Hospital of the University of Pennsylvania has just received bequest of $10,000, the income of which is to be applied to the support of fr beds for cases of recent accidents.

—

West Virginia State Board of Health.—The Legislature of West Virginia h just passed a bill establishing a State board of health with power to appoint local board in each county, and regulating the practice of medicine.

—

Night Medical Service.—A bill to establish a night medical service in Brook lyn has been favourably reported by the Committee on Public Health. Th New York night medical service responded to forty-one calls for assistance January, and to sixty calls in February.

—

Epidemic among Horses.—A new equine epidemic, characterized by th simultaneous occurrence of symptoms resembling those of glanders and of spin meningitis has prevailed in the stables of several New York horse-car compani during the last few weeks. It is rarely fatal.

—

Prize Awarded to Mr. Lister.—At the meeting of the Academy of Scienc in Paris on March 12th, the Bondet prize of 6000 francs ($1200) was awarde Professor Lister, for his application of M. Pasteur's researches to the improv ment of the art of healing.

Meetings of National and State Medical Societies will be held during the month of May as follows:—

American Medical Association at Richmond, Va., on Tuesday, May 3.
American Laryngological Association, at Philadelphia, on Tuesday, May 10.
State Medical Society of Arkansas, at Little Rock, on Wednesday, May 4.
Iowa State Medical Society, at Dubuque, on Wednesday, May 25.
State Medical Society of Kansas, at Topeka, on Tuesday, May 10.
Medical Association of the State of Missouri, at Mexico, on Tuesday, May 17.
Medical Society of North Carolina, at Asheville, on Tuesday, May 31.
Pennsylvania State Medical Society, at Lancaster, on Wednesday, May 11.

—

Guy's Hospital.—The nursing question at Guy's is virtually ended by the adoption of a series of new regulations for the nurses, which have been submitted to and approved by the medical officers, and which we are glad to learn concede all for which they had contended. Under the new regulations the nurses are placed under the direction of the medical officers.

—

Library of the New York Academy of Medicine.—Dr. Fordyce Barker, President of the Academy, has intimated his generous intention of giving to the Academy a collection of books, which he is seeking to make as complete as possible, in the department of obstetrics and gynæcology.

—

A Good Example for Hospital Managers.—A wise and proper recognition of the medical staff has lately been shown in the government of St. Bartholomew's Hospital, London, by the election of four members of the staff as members of the Board of Governors. We commend the example to the governing boards of all hospitals.

—

Banquet to an American Consul.—In the beginning of March a banquet was given by many of the leading citizens of Bristol, England, to the Hon. Theodore Canisius, M.D., who, after six years' residence there as United States Consul, was about to leave the city. At the conclusion of the banquet an address was presented to Dr. Canisius, signed by the Mayor of Bristol and several of its more influential inhabitants.

—

Another Literary Piracy.

A few months ago we were constrained to expose the piracy by a London publishing house of Dr. Keen's "American Health Primer" series, and now we are under the similar necessity of calling attention to another piracy which is, if possible, even more disgraceful, inasmuch as it not only appropriates the work of an American author, but also publishes it under the name of a young London physician.

About a year and a half ago Dr. George R. Cutter, of New York, as "the result of many years of industrious research," published a very useful "Dictionary of the German Terms used in Medicine," which was favourably received by the profession. Mr. H. K. Lewis, of London, has just issued a "German-English Dictionary of Words and Terms used in Medicine," by Fancourt Barnes, Physician to the British Lying-in Hospital. In a letter to the *Medical Record* Dr. Cutter says of it, "After a careful examination I find that Dr. Barnes has copied

nearly every one of my words, with their definitions; the latter in the same sequence and with the same punctuation. The few typographical and other errors which escaped correction in the first edition and remained in my plates have, in nearly every instance, been so faithfully copied as to appear ludicrous, were it not for the fact that this alone affords sufficient proof of a shameless piracy. . . . In short there is not a page in his book which does not reveal the fact that he has stolen my whole work, adding a very few medical words and a number of chemical and zoological terms which may be found in the ordinary German dictionaries. I do not find more than a score of my words omitted, and the two books contain the same number of pages."

—

OBITUARY RECORD.—Died at Philadelphia on the 31st of March, in the 75th year of his age, ISAAC RAY, M.D., LL.D., formerly superintendent of the Butler Hospital for the Insane, Providence, Conn. Dr. Ray was widely known as an eminent authority in all matters relating to insanity, and his writings are held in the highest esteem. He was born at Beverly, Mass., in 1807, graduated in Bowdoin College, and commenced the practice of medicine in 1827. He was one of the originators of the Association of Medical Superintendents of American Institutions for the Insane and was its President from 1855 to 1859. A biographical sketch of Dr. Ray will appear in the next number of the *American Journal of the Medical Sciences*, to which journal he was a frequent contributor.

—— At Louisville on April 2d, aged 42 years, RICHARD OSWALD COWLING, M.D., Editor of the *Louisville Medical News*, and Professor of Surgery in the University of Louisville.

Dr. Cowling was prominent among Kentucky's most eminent surgeons, gifted citizens, and beloved sons. His personal traits are thus described in a minute adopted by the Medical Faculty of the University of Louisville: "As a teacher, Dr. Cowling was comprehensive, luminous, and exact; as an operator, bold but cautious, daring but prudent; as a man, dignified, upright, generous, brave, with a child's simplicity of ways and disposition. A scholar of rare attainments; a thinker original, logical, sustained; a writer incisive, varied; a successful author, he added to the fame of the University which he entered as a pupil and where in time he rose to the rank of professor, a position which he in every way adorned.

At a meeting of the physicians of Louisville, held April 4th, the following resolutions were adopted.

Whereas, Providence has removed by death Dr. Richard O. Cowling, a valued and distinguished member of the medical profession of this city, and a man known and appreciated by this community; therefore

Resolved, That in the death of Dr. Cowling the profession has lost a member of gifted and brilliant qualities, of rare social virtues, and goodness of heart.

Resolved, That in all the relations of life he has shown himself a man of generous nature, a sincere friend, a faithful husband, and an indulgent father.

Resolved, That we tender to his family—father, mother, sister, brothers, widow and children—our condolence for the loss they have sustained by his death, and that a copy of these resolutions be transmitted to them by the officers of this meeting as indicative of our sorrow for them in this hour of sudden affliction.

—

To Readers and Correspondents.—The Editor will be happy to receive early intelligence of local events of general medical interest, or which it is desirable to bring to the notice of the profession. Local papers containing reports or news items should be marked.

HENRY C. LEA'S SON & CO.'S

(LATE HENRY C. LEA)

CLASSIFIED CATALOGUE

OF

MEDICAL AND SURGICAL PUBLICATIONS.

In asking the attention of the profession to the works advertised in the following pages, the publishers would state that no pains are spared to secure a continuance of the confidence earned for the publications of the house by their careful selection and accuracy and finish of execution.

The large number of inquiries received from the profession for a finer class of bindings than is usually placed on medical books has induced us to put certain of our standard publications in half Russia, and that the growing taste may be encouraged, the prices have been fixed at so small an advance over the cost of sheep, as to place it within the means of all to possess a library that shall have attractions as well for the eye as for the mind of the reading practitioner.

The printed prices are those at which books can generally be supplied by booksellers throughout the United States, who can readily procure for their customers any works not kept in stock. Where access to bookstores is not convenient, books will be sent by mail post-paid on receipt of the price, and as the limit of mailable weight has been removed, no difficulty will be experienced in obtaining through the post-office any work in this catalogue. No risks, however, are assumed either on the money or on the books, and no publications but our own are supplied, so that gentlemen will in most cases find it more convenient to deal with the nearest bookseller.

HENRY C. LEA'S SON & CO.

Nos. 706 and 708 SANSOM ST., PHILADELPHIA, May, 1881.

INCREASED INDUCEMENT FOR SUBSCRIBERS TO

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

TWO MEDICAL JOURNALS, containing nearly 2000 LARGE PAGES,

Free of Postage, for FIVE DOLLARS Per Annum.

TERMS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), with THE MEDICAL NEWS AND ABSTRACT, monthly (768 pp. per annum), } Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance, Five Dollars.

THE MEDICAL NEWS AND ABSTRACT, free of postage, in advance, Two Dollars and a half.

*** Advance paying subscribers can obtain at the close of the year cloth covers, gilt-lettered, for each volume of the Journal (two annually), and of the News and Abstract (one annually), free by mail, by remitting ten cents for each cover.

It will thus be seen that for the moderate sum of FIVE DOLLARS in advance, the subscriber will receive, free of postage, the equivalent of four large octavo volumes, stored with the choicest matter, original and selected, that can be furnished by the medical literature of both hemispheres. Thus taken together, the "JOURNAL" and the "NEWS AND ABSTRACT" combine the advantages of the elaborate preparation that can be devoted to the Quarterly with the prompt conveyance of intelligence by the Monthly; while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable when periodicals from different sources are taken together.

The periodicals thus offered at this unprecedented rate are universally known for

their high professional standing.

I.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES

EDITED BY I. MINIS HAYS, M.D.,

for more than half a century has maintained its position in the front rank of medical literature of the world. Cordially supported by the profession of Americ circulates wherever the language is read, and is universally regarded as the nati exponent of American medicine—a position to which it is entitled by the distinguis names from every section of the Union which are to be found among its collaborato It is issued quarterly, in January, April, July, and October, each number contai about three hundred octavo pages, appropriately illustrated wherever necessary. large portion of this space is devoted to Original Communications, embracing pa from the most eminent members of the profession throughout the country.

Following this is the REVIEW DEPARTMENT, containing extended reviews by c petent writers of prominent new works and topics of the day, together with nume elaborate Analytical and Bibliographical Notices, giving a fairly complete surve medical literature.

Then follows the QUARTERLY SUMMARY OF IMPROVEMENTS AND DISCOVE IN THE MEDICAL SCIENCES, classified and arranged under different heads, and f ishing a digest of medical progress, abroad and at home.

Thus during the year 1880 the "JOURNAL" contained 67 Original Communicati mostly elaborate in character, 170 Reviews and Bibliographical Notices, and 147 art in the Quarterly Summaries, illustrated with 47 wood engravings.

That the efforts thus made to maintain the high reputation of the "JOURNAL" successful, is shown by the position accorded to it in both America and Europe a leading organ of medical progress:—

This is universally acknowledged as the leading American Journal, and has been conducted by Dr. Hays alone until 1869, when his son was associated with him. We quite agree with the critic, that this journal is second to none in the language, and cheerfully accord to it the first place, for nowhere shall we find more able and more impartial criticism, and nowhere such a repertory of able original articles. Indeed, now that the "British and Foreign Medico-Chirurgical Review" has terminated its career, the American Journal stands without a rival.—*London Med. Times and Gazette*, Nov. 24, 1877.

The best medical journal on the continent.—*Boston Med. and Surg. Journal*, April, 1879.

The present number of the American Journal is an exceedingly good one, and gives every promise of maintaining the well-earned reputation of the review. Our venerable contemporary has our best wishes, and we can only express the hope that it may continue its work with as much vigor and excellence for the next fifty years as it has exhibited in the past.—*London Lancet*, Nov. 24, 1877.

The Philadelphia Medical and Physical Jo issued its first number in 1820, and, after a bri career, was succeeded in 1827 by the Ame Journal of the Medical Sciences, a periodic world-wide reputation; the ablest and one o oldest periodicals in the world—a journal whic an unsullied record.—*Gross's History of Ame Med. Literature* 1876.

The best medical journal ever published in E or America.—*Va. Med. Monthly*, May, 1879.

It is universally acknowledged to be the le American medical journal, and, in our opini second to none in the language.—*Boston Med Surg. Journal*, Oct. 1877.

This is the medical journal of our country to the American physician abroad will point wi greatest satisfaction, as reflecting the state of cal culture in his country. For a great many it has been the medium through which our writers have made known their discoverie observations.—*Address of L. P. Yandell, M. fore International Med. Congress*, Sept. 1876

And that it was specifically included in the award of a medal of merit to the lishers in the Vienna Exhibition in 1873.

The subscription price of the "AMERICAN JOURNAL OF THE MEDICAL SCIEN has never been raised during its long career. It is still FIVE DOLLARS per an and when paid for in advance, the subscriber receives in addition the "MED NEWS AND ABSTRACT," making in all nearly 2000 large octavo pages per annum of postage.

II.

THE MEDICAL NEWS AND ABSTRACT.

Thirty-eight years ago the "MEDICAL NEWS" was commenced as a month convey to the subscribers of the "AMERICAN JOURNAL" the clinical instructio

* Communications are invited from gentlemen in all parts of the country. Articles inserted Editor are liberally paid for by the publishers.

current information which could not be accommodated in the Quarterly. It consisted of sixteen pages of such matter, together with sixteen more known as the Library Department and devoted to the publishing of books. With the increased progress of science, however, this was found insufficient, and some years since another periodical, known as the "MONTHLY ABSTRACT," was started, and was furnished at a moderate price to subscribers to the "AMERICAN JOURNAL." These two monthlies have been consolidated, under the title of "THE MEDICAL NEWS AND ABSTRACT," and are furnished *free of charge* in connection with the "AMERICAN JOURNAL."

The "NEWS AND ABSTRACT" consists of 64 pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, by gentlemen of the highest reputation throughout the United States, together with a choice selection of foreign Lectures and Hospital Notes and Gleanings. Then follows the MONTHLY ABSTRACT, systematically arranged and classified, and presenting five or six hundred articles yearly; and each number concludes with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

As stated above, the subscription price to the "NEWS AND ABSTRACT" is Two Dollars and a Half per annum, invariably in advance, at which rate it ranks as one of the cheapest medical periodicals in the country. But it is also furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

In this effort to furnish so large an amount of practical information at a price so unprecedentedly low, and thus place it within the reach of every member of the profession, the publishers confidently anticipate the friendly aid of all who feel an interest in the dissemination of sound medical literature. They trust, especially, that the subscribers to the "AMERICAN MEDICAL JOURNAL," will call the attention of their acquaintances to the advantages thus offered, and that they will be sustained in the endeavor to permanently establish medical periodical literature on a footing of cheapness never heretofore attempted.

PREMIUM FOR OBTAINING NEW SUBSCRIBERS TO THE "JOURNAL."

Any gentleman who will remit the amount for two subscriptions for 1881, one of which at least must be for a *new subscriber*, will receive as a PREMIUM, free by mail, a copy of any one of the following recent works:—

"SEILER ON THE THROAT" (see p. 19),
"BARNES'S MANUAL OF MIDWIFERY" (see p. 25),
"TILBURY FOX'S EPITOME OF DISEASES OF THE SKIN," new edition (see p. 18),
"BROWNE ON THE USE OF THE OPHTHALMOSCOPE" (see p. 29),
"FLINT'S ESSAYS ON CONSERVATIVE MEDICINE" (see p. 15),
"STURGES'S CLINICAL MEDICINE" (see p. 15),
"SWAYNE'S OBSTETRIC APHORISMS," new edition (see p. 21),
"TANNER'S CLINICAL MANUAL" (see p. 5),
"WEST ON NERVOUS DISORDERS OF CHILDREN" (see p. 21).

*** Gentlemen desiring to avail themselves of the advantages thus offered will do well to forward their subscriptions at an early day, in order to insure the receipt of complete sets for the year 1881.

☞ The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" may be made at the risk of the publishers, by forwarding in REGISTERED letters. Address,

HENRY C. LEA'S SON & CO., Nos. 706 and 708 Sansom St., Phila., Pa.

DUNGLISON (*ROBLEY*), *M.D.*,

Late Professor of Institutes of Medicine in Jefferson Medical College, Philadelphia.

MEDICAL LEXICON; A DICTIONARY OF MEDICAL SCIENCE: C

taining a concise explanation of the various Subjects and Terms of Anatomy, Physiol Pathology, Hygiene, Therapeutics, Pharmacology, Pharmacy, Surgery, Obstetrics, Me Jurisprudence, and Dentistry. Notices of Climate and of Mineral Waters; Formula Officinal, Empirical, and Dietetic Preparations; with the Accentuation and Etymolo the Terms, and the French and other Synonymes; so as to constitute a French as we English Medical Lexicon. A New Edition. Thoroughly Revised, and very greatly i ified and Augmented. By RICHARD J. DUNGLISON, M.D. In one very large and h some royal octavo volume of over 1100 pages. Cloth, $6 50; leather, raised bands, $7 half Russia, $8. (*Just Issued.*)

The object of the author from the outset has not been to make the work a mere lexico dictionary of terms, but to afford, under each, a condensed view of its various medical relat and thus to render the work an epitome of the existing condition of medical science. Sta with this view, the immense demand which has existed for the work has enabled him, in repe revisions, to augment its completeness and usefulness, until at length it has attained the pos of a recognized and standard authority wherever the language is spoken.

Special pains have been taken in the preparation of the present edition to maintain thi viable reputation. During the ten years which have elapsed since the last revision, the addi to the nomenclature of the medical sciences have been greater than perhaps in any similar p of the past, and up to the time of his death the author labored assiduously to incorporate e thing requiring the attention of the student or practitioner. Since then, the editor has equally industrious, so that the additions to the vocabulary are more numerous than in any vious revision. Especial attention has been bestowed on the accentuation, which will be f marked on every word. The typographical arrangement has been much improved, rend reference much more easy, and every care has been taken with the mechanical execution. work has been printed on new type, small but exceedingly clear, with an enlarged page, so the additions have been incorporated with an increase of but little over a hundred pages the volume now contains the matter of at least four ordinary octavos.

A book well known to our readers, and of which every American ought to be proud. When the learned author of the work passed away, probably all of us feared lest the book should not maintain its place in the advancing science whose terms it defines. Fortunately, Dr. Richard J. Dunglison, having assisted his father in the revision of several editions of the work, and having been, therefore, trained in the methods and imbued with the spirit of the book, has been able to edit it, not in the patchwork manner so dear to the heart of book editors, so repulsive to the taste of intelligent book readers, but to edit it as a work of the kind should be edited—to carry it on steadily, without jar or interruption, along the grooves of thought it has travelled during its lifetime. To show the magnitude of the task which Dr. Dunglison has assumed and carried through, it is only necessary to state that more than six thousand new subjects have been added in the present edition.—*Phila. Med. Times*, Jan. 3, 1874.

About the first book purchased by the medical student is the Medical Dictionary. The lexicon explanatory of technical terms is simply a *sine qua non*. In a science so extensive, and with such collaterals as medicine, it is as much a necessity also to the practising physician. To meet the wants of students and most physicians, the dictionary must be condensed while comprehensive, and practical while perspicacious. It was because Dunglison's met these indications that it became at once the dictionary of general use wherever medicine was studied in the English language. In no former revision have the alterations and additions been so great. More than six thousand new subjects and terms have been added. The chief terms have been set in black letter, while the derivatives follow in small caps; an arrangement which greatly facilitates reference. We may safely confirm the hope ventured by the "that the work, which possesses for him a filial as an individual interest, will be found worthy tinuance of the position so long accorded to standard authority."—*Cincinnati Clinic*, Jan. 10

It has the rare merit that it certainly has n in the English language for accuracy and ext references.—*London Medical Gazette*.

As a standard work of reference, as one of the if not the very best, medical dictionary in the lish language, Dunglison's work has been well for about forty years, and needs no words of on our part to recommend it to the members medical, and, likewise, of the pharmaceutica fession. The latter especially are in need of work, which gives ready and reliable inform on thousands of subjects and terms which th liable to encounter in pursuing their daily tions, but with which they cannot be expected familiar. The work before us fully supplie want.—*Am. Journ. of Pharm.*, Feb. 1874.

A valuable dictionary of the terms employ medicine and the allied sciences, and of the tions of the subjects treated under each head. flects great credit on its able American autho well deserves the authority and popularity obtained.—*British Med. Journ.*, Oct. 31, 1874.

Few works of this class exhibit a grander ment of patient research and of scientific lore. extent of the sale of this lexicon is sufficient tify to its usefulness, and to the great servic ferred by Dr. Robley Dunglison on the profe and indeed on others, by its issue.—*London L* May 13 1875.

HOBLYN (*RICHARD D.*), *M.D*

A DICTIONARY OF THE TERMS USED IN MEDICINE A

THE COLLATERAL SCIENCES. Revised, with numerous additions, by ISAAC H M. D., Editor of the "American Journal of the Medical Sciences." In one large 12mo. volume of over 500 double-columned pages; cloth, $1 50; leather, $2 00

It is the best book of definitions we have, and ought always to be upon the student's table.—*Sou Med. and Surg. Journal.*

RODWELL (*G. F.*), *F.R.A.S., &c.*

A DICTIONARY OF SCIENCE: Comprising Astronomy, Ch istry, Dynamics, Electricity, Heat, Hydrodynamics, Hydrostatics, Light, Magne Mechanics, Meteorology, Pneumatics, Sound, and Statics. Preceded by an Essay o History of the Physical Sciences. In one handsome octavo volume of 694 pages, many illustrations: cloth, $5.

A CENTURY OF AMERICAN MEDICINE, 1776–1876. By Doctors E. H. Clarke, H. J. Bigelow, S. D. Gross, T. G. Thomas, and J. S. Billings. In one very handsome 12mo. volume of about 350 pages: cloth, $2 25. (*Lately Issued.*)

This work appeared in the pages of the American Journal of the Medical Sciences during the year 1876. As a detailed account of the development of medical science in America, by gentlemen of the highest authority in their respective departments, the profession will no doubt welcome it in a form adapted for preservation and reference.

NEILL (*JOHN*), *M.D.*, *and* SMITH (*FRANCIS G.*), *M.D.*,
Prof. of the Institutes of Medicine in the Univ. of Penna.

AN ANALYTICAL COMPENDIUM OF THE VARIOUS BRANCHES OF MEDICAL SCIENCE; for the Use and Examination of Students. A new edition, revised and improved. In one very large and handsomely printed royal 12mo. volume, of about one thousand pages, with 374 wood-cuts, cloth, $4; strongly bound in leather, with raised bands, $4 75.

HARTSHORNE (*HENRY*), *M.D.*,
Professor of Hygiene in the University of Pennsylvania.

A CONSPECTUS OF THE MEDICAL SCIENCES; containing Handbooks on Anatomy, Physiology, Chemistry, Materia Medica, Practical Medicine, Surgery, and Obstetrics. Second Edition, thoroughly revised and improved. In one large royal 12mo. volume of more than 1000 closely printed pages, with 477 illustrations on wood. Cloth, $4 25; leather, $5 00. (*Lately Issued.*)

We can say with the strictest truth that it is the best work of the kind with which we are acquainted. It embodies in a condensed form all recent contributions to practical medicine, and is therefore useful to every busy practitioner throughout our country, besides being admirably adapted to the use of students of medicine. The book is faithfully and ably executed.—*Charleston Med. Journ.*, April, 1875.

The work is intended as an aid to the medical student, and as such appears to admirably fulfil its object by its excellent arrangement, the full compilation of facts, the perspicuity and terseness of language, and the clear and instructive illustrations in some parts of the work.—*American Journ. of Pharmacy*, Philadelphia, July, 1874.

The volume will be found useful, not only to students, but to many others who may desire to refresh their memories with the smallest possible expenditure of time.—*N. Y. Med. Journal*, Sept. 1874.

The student will find this the most convenient and useful book of the kind on which he can lay his hand.—*Pacific Med. and Surg. Journ.*, Aug. 1874.

This is the best book of its kind that we have ever examined. It is an honest, accurate, and concise compend of medical sciences, as fairly as possible representing their present condition. The changes and the additions have been so judicious and thorough as to render it, so far as it goes, entirely trustworthy. If students must have a conspectus, they will be wise to procure that of Dr. Hartshorne.—*Detroit Rev. of Med. and Pharm.*, Aug. 1874.

The work before us has many redeeming features not possessed by others, and is the best we have seen. Dr. Hartshorne exhibits much skill in condensation. It is well adapted to the physician in active practice, who can give but limited time to the familiarizing of himself with the important changes which have been made since he attended lectures. The manual of physiology has also been improved and gives the most comprehensive view of the latest advances in the science possible in the space devoted to the subject. The mechanical execution of the book leaves nothing to be wished for.—*Peninsular Journal of Medicine*, Sept. 1874.

After carefully looking through this conspectus, we are constrained to say that it is the most complete work, especially in its illustrations, of its kind that we have seen.—*Cincinnati Lancet*, Sept. 1874.

The favor with which the first edition of this Compendium was received, was an evidence of its various excellences. The present edition bears evidence of a careful and thorough revision. Dr. Hartshorne possesses a happy faculty of seizing upon the salient points of each subject, and of presenting them in a concise and yet perspicuous manner.—*Leavenworth Med. Herald*, Oct. 1874

LUDLOW (*J. L.*), *M.D.*

A MANUAL OF EXAMINATIONS upon Anatomy, Physiology, Surgery, Practice of Medicine, Obstetrics, Materia Medica, Chemistry, Pharmacy, and Therapeutics. To which is added a Medical Formulary. Third edition, thoroughly revised and greatly extended and enlarged. With 370 illustrations. In one handsome royal 12mo. volume of 816 large pages. Cloth, $3 25; leather, $3 75.

The arrangement of this volume in the form of question and answer renders it especially suitable for the office examination of students, and for those preparing for graduation.

TANNER (*THOMAS HAWKES*), *M.D.*, *&c.*

A MANUAL OF CLINICAL MEDICINE AND PHYSICAL DIAGNOSIS. Third American from the Second London Edition. Revised and Enlarged by TILBURY FOX, M. D., Physician to the Skin Department in University College Hospital, London, &c. In one neat volume small 12mo., of about 375 pages, cloth, $1 50.

*** On page 3, it will be seen that this work is offered as a premium for procuring new subscribers to the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES."

GRAY (HENRY), F.R.S.,

Lecturer on Anatomy at St. George's Hospital, London.

ANATOMY, DESCRIPTIVE AND SURGICAL. The Drawings

H. V. CARTER, M.D., and Dr. WESTMACOTT. The Dissections jointly by the AUTHORS Dr. CARTER. With an Introduction on General Anatomy and Development by HOLMES, M.A., Surgeon to St George's Hospital. A new American, from the Eigh enlarged and improved London edition To which is added "LANDMARKS, MEDICAL A SURGICAL," by LUTHER HOLDEN, F.R.C.S., author of "Human Osteology," "A Manu of Dissections," etc. In one magnificent imperial octavo volume of 983 pages, wi 522 large and elaborate engravings on wood. Cloth, $6; leather, raised bands, $ half Russia, $7 50. (*Now Ready.*)

The author has endeavored in this work to cover a more extended range of subjects than is c tomary in the ordinary text-books, by giving not only the details necessary for the student, l also the application of those details in the practice of medicine and surgery, thus rendering it b a guide for the learner, and an admirable work of reference for the active practitioner. The gravings form a special feature in the work, many of them being the size of nature, nearly original, and having the names of the various parts printed on the body of the cut, in place figures of reference, with descriptions at the foot. They thus form a complete and splendid seri which will greatly assist the student in obtaining a clear idea of Anatomy, and will also serve refresh the memory of those who may find in the exigencies of practice the necessity of recalli the details of the dissecting room; while combining, as it does, a complete Atlas of Anatomy, w a thorough treatise on systematic, descriptive, and applied Anatomy, the work will be found essential use to all physicians who receive students in their offices, relieving both preceptor a pupil of much labor in laying the groundwork of a thorough medical education.

Since the appearance of the last American Edition, the work has received three revisions at t hands of its accomplished editor, Mr. Holmes, who has sedulously introduced whatever has seem requisite to maintain its reputation as a complete and authoritative standard text-book and wo of reference. Still further to increase its usefulness, there has been appended to it the rece work by the distinguished anatomist, Mr. Luther Holden—"Landmarks, Medical and Surgica —which gives in a clear, condensed and systematic way, all the information by which the pra titioner can determine from the external surface of the body the position of internal parts. Th complete, the work, it is believed, will furnish all the assistance that can be rendered by type illustration in anatomical study. No pains have been spared in the typographical execution the volume, which will be found in all respects superior to former issues. Notwithstanding t increase of size, amounting to over 100 pages and 57 illustrations, it will be kept, as heretofo at a price rendering it one of the cheapest works ever offered to the American profession.

The recent work of Mr. Holden, which was noticed by us on p. 53 of this volume, has been added as an appendix, so that, altogether, this is the most practical and complete anatomical treatise available to American students and physicians. The former finds in it the necessary guide in making dissections; a very comprehensive chapter on minute anatomy; and about all that can be taught him on general and special anatomy; while the latter, in its treatment of each region from a surgical point of view, and in the valuable addition of Mr. Holden, will find all that will be essential to him in his practice.—*New Remedies*, Aug. 1878.

This work is as near perfection as one could possibly or reasonably expect any book intended as a text-book or a general reference book on anatomy to be. The American publisher deserves the thanks of the profession for appending the recent work of Mr. Holden, "*Landmarks, Medical and Surgical*," which has already been commended as a separate book. The latter work—treating of topographical anatomy—has become an essential to the library of every intelligent practitioner. We know of no book that can take its place, written as it is by a most distinguished anatomist. It would be simply a waste of words to say anything further in praise of Gray's Anatomy, the text-book in almost every medical college in this country, and the daily reference book of every practitioner who has occasion to consult his books on anatomy. The work simply indispensable, especially this present American edition.—*Va. Med. Monthly*, Sept. 1878.

The addition of the recent work of Mr. Holde as an appendix, renders this the most practical a complete treatise available to American studen who find in it a comprehensive chapter on mins anatomy, about all that can be taught on gene and special anatomy, while its treatment of ea region, from a surgical point of view, in the va able section by Mr Holden, is all that will be esse tial to them in practice.—*Ohio Medical Record* Aug 1878.

It is difficult to speak in moderate terms of th new edition of "Gray." It seems to be as near perfect as it is possible to make a book devoted any branch of medical science. The labors of t eminent men who have successively revised t eight editions through which it has passed, wou seem to leave nothing for future editors to do. T addition of Holden's "Landmarks" will make it indispensable to the practitioner of medicine a surgery as it has been heretofore to the student. regards completeness, ease of reference, utilit beauty, and cheapness, it has no rival. No st dent should enter a medical school without it; physician can afford to have it absent from h library.—*St. Louis Clin. Record*, Sept. 1878.

ALSO FOR SALE SEPARATE—

HOLDEN (LUTHER), F.R.C.S.,

Surgeon to St. Bartholomew's and the Foundling Hospitals.

LANDMARKS, MEDICAL AND SURGICAL. Second American

PRACTICAL ANATOMY: A Manual of Dissections. From th

Second revised and improved London edition. Edited, with additions, by W. W. KEEN M. D., Lecturer on Pathological Anatomy in the Jefferson Medical College, Philadelphia In one handsome royal 12mo. volume of 578 pages, with 247 illustrations Cloth, $3 50 leather, $4 00.

ALLEN (HARRISON), M.D.
Professor of Physiology in the Univ. of Pa.

A SYSTEM OF HUMAN ANATOMY: INCLUDING ITS MEDICAL and Surgical Relations. For the Use of Practitioners and Students of Medicine. With an Introductory Chapter on Histology. By E. O. SHAKESPEARE, M D, Ophthalmologist to the Phila. Hosp. In one large and handsome quarto volume, with several hundred original illustrations on lithographic plates, and numerous wood-cuts in the text. (*Shortly.*)

In this elaborate work, which has been in active preparation for several years, the author has sought to give, not only the details of descriptive anatomy in a clear and condensed form, but also the practical applications of the science to medicine and surgery. The work thus has claims upon the attention of the general practitioner, as well as of the student, enabling him not only to refresh his recollections of the dissecting room, but also to recognize the significance of all variations from normal conditions. The marked utility of the object thus sought by the author is self-evident, and his long experience and assiduous devotion to its thorough development are a sufficient guarantee of the manner in which his aims have been carried out. No pains have been spared with the illustrations. Those of normal anatomy are from original dissections, drawn on stone by Mr. Hermann Faber, with the name of every part clearly engraved upon the figure, after the manner of "Holden" and "Gray," and in every typographical detail it will be the effort of the publishers to render the volume worthy of the very distinguished position which is anticipated for it.

ELLIS (GEORGE VINER).
Emeritus Professor of Anatomy in University College, London.

DEMONSTRATIONS OF ANATOMY; Being a Guide to the Knowledge of the Human Body by Dissection. By GEORGE VINER ELLIS, Emeritus Professor of Anatomy in University College, London. From the Eighth and Revised London Edition. In one very handsome octavo volume of over 700 pages, with 256 illustrations. Cloth, $4.25; leather, $5.25 (*Now Ready.*)

This work has long been known in England as the leading authority on practical anatomy, and the favorite guide in the dissecting-room, as is attested by the numerous editions through which it has passed. In the last revision, which has just appeared in London, the accomplished author has sought to bring it on a level with the most recent advances of science by making the necessary changes in his account of the microscopic structure of the different organs, as developed by the latest researches in textural anatomy.

Ellis's Demonstrations is the favorite text-book of the English student of anatomy. In passing through eight editions it has been so revised and adapted to the needs of the student that it would seem that it had almost reached perfection in this special line. The descriptions are clear, and the methods of pursuing anatomical investigations are given with such detail that the book is honestly entitled to its name.—*St. Louis Clinical Record*, June, 1879.

The success of this old manual seems to be as well deserved in the present as in the past volumes. The book seems destined to maintain yet for years its leadership over the English manuals upon dissecting.—*Phila. Med. Times*, May 24, 1879.

As a dissector, or a work to have in hand and studied while one is engaged in dissecting, we regard it as the very best work extant, which is certainly saying a very great deal. As a text-book to be studied in the dissecting-room, it is superior to any of the works upon anatomy.—*Cincinnati Med. News*, May 24, 1879.

We most unreservedly recommend it to every practitioner of medicine who can possibly get it.—*Va. Med. Monthly*, June, 1879.

WILSON (ERASMUS), F.R.S.

A SYSTEM OF HUMAN ANATOMY, General and Special. Edited by W. H. GOBRECHT, M.D, Professor of General and Surgical Anatomy in the Medical College of Ohio. Illustrated with three hundred and ninety-seven engravings on wood. In one large and handsome octavo volume, of over 600 pages; cloth, $4; leather, $5.

SMITH (HENRY H.), M.D., and HORNER (WILLIAM E.), M.D.,
Prof. of Surgery in the Univ. of Penna., &c. *Late Prof. of Anatomy in the Univ. of Penna.*

AN ANATOMICAL ATLAS; Illustrative of the Structure of the Human Body. In one volume, large imperial octavo, cloth, with about six hundred and fifty beautiful figures. $4 50.

SCHÄFER (EDWARD ALBERT), M.D.,
Assistant Professor of Physiology in University College, London.

A COURSE OF PRACTICAL HISTOLOGY: Being an Introduction to the Use of the Microscope. In one handsome royal 12mo. volume of 304 pages, with numerous illustrations: cloth, $2 00. (*Just Issued.*)

HORNER'S SPECIAL ANATOMY AND HISTOLOGY. Eighth edition, extensively revised and modified In 2 vols. 8vo., of over 1000 pages, with 320 wood cuts: cloth, $6 00.

SHARPEY AND QUAIN'S HUMAN ANATOMY. Revised, by JOSEPH LEIDY, M.D., Prof of Anat. in Univ. of Penn. In two octavo vols. of about 1300 pages, with 511 illustrations Cloth, $6 00.

BELLAMY'S STUDENT'S GUIDE TO SURGICAL ANATOMY: A Text-book for Students preparing for their Pass Examination. With engravings on wood In one handsome royal 12mo. volume. Cloth, $2 25.

CLELAND'S DIRECTORY FOR THE DISSECTION OF THE HUMAN BODY. In one small volume, royal 12mo. of 182 pages: cloth $1 25.

HARTSHORNE'S HANDBOOK OF ANATOMY AND PHYSIOLOGY. Second edition, revised. In one royal 12mo. vol., with 220 wood cuts; cloth $1 75.

DALTON (J. C.), M.D.,

Professor of Physiology in the College of Physicians and Surgeons, New York, &c.

A TREATISE ON HUMAN PHYSIOLOGY. Designed for the use of Students and Practitioners of Medicine. Sixth edition, thoroughly revised and enlarged, with three hundred and sixteen illustrations on wood. In one very beautiful octavo volume, of over 800 pages. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Lately Issued.*)

During the past few years several new works on physiology, and new editions of old works, have appeared, competing for the favor of the medical student, but none will rival this new edition of Dalton. As now enlarged, it will be found also to be, in general, a satisfactory work of reference for the practitioner.—*Chicago Med. Journ. and Examiner*, Jan. 1876.

Prof. Dalton has discussed conflicting theories and conclusions regarding physiological questions with a fairness, a fulness, and a conciseness which lend freshness and vigor to the entire book. But his discussions have been so guarded by a refusal of admission to those speculative and theoretical explanations, which at best exist in the minds of observers themselves as only probabilities, that none of his readers need be led into grave errors while making them a study.—*The Medical Record*, Feb. 19, 1876.

The revision of this great work has brought it forward with the physiological advances of the day, and renders it, as it has ever been, the finest work for students extant.—*Nashville Journ. of Med. and Surg.*, Jan. 1876.

For clearness and perspicuity, Dalton's Physiology commended itself to the student years ago, and was a pleasant relief from the verbose productions which it supplanted. Physiology has, however, made many advances since then—and while the style has been preserved intact, the work in the present edition has been brought up fully abreast of the times. The new chemical notation and nomenclature have also been introduced into the present edition. Notwithstanding the multiplicity of text-books on physiology, this will lose none of its old time popularity. The mechanical execution of the work is all that could be desired.—*Peninsular Journal of Medicine*, Dec. 1875.

This popular text-book on physiology comes to us in its sixth edition with the addition of about fifty per cent of new matter, chiefly in the departments of pathological chemistry and the nervous system, where the principal advances have been realized. With so thorough revision and additions, that keep the work well up to the times, its continued popularity may be confidently predicted, notwithstanding the competition it may encounter. The publisher's work is admirably done.—*St. Louis Med. and Surg. Journ.*, Dec. 1875.

We heartily welcome this, the sixth edition of this admirable text-book, than which there are none of equal brevity more valuable. It is cordially recommended by the Professor of Physiology in the University of Louisiana, as by all competent teachers in the United States and wherever the English language is read, this book has been appreciated. The present edition, with its 316 admirably executed illustrations, has been carefully revised and very much enlarged, although its bulk does not seem perceptibly increased.—*New Orleans Medical and Surgical Journal*, March, 1876.

CARPENTER (WILLIAM B.), M. D., F. R. S., F.G.S., F.L.S.,

Registrar to University of London, etc.

PRINCIPLES OF HUMAN PHYSIOLOGY; Edited by HENRY POWER, M.B. Lond., F.R.C.S., Examiner in Natural Sciences, University of Oxford. A new American from the Eighth Revised and Enlarged English Edition, with Notes and Additions, by FRANCIS G. SMITH, M.D., Professor of the Institutes of Medicine in the University of Pennsylvania, etc. In one very large and handsome octavo volume, of 1083 pages, with two plates and 373 engravings on wood. Cloth, $5 50; leather, $6 50; half Russia $7. (*Just Issued.*)

We have been agreeably surprised to find the volume so complete in regard to the structure and functions of the nervous system in all its relations, a subject that, in many respects, is one of the most difficult of all, in the whole range of physiology, upon which to produce a full and satisfactory treatise of the class to which the one before us belongs. The additions by the American editor give to the work as it is a considerable value beyond that of the last English edition. In conclusion, we can give our cordial recommendation to the work as it now appears. The editors have, with their additions to the only work on physiology in our language that, in the fullest sense of the word, is the production of a philosopher as well as a physiologist, brought it up as fully as could be expected, if not desired, to the standard of our knowledge of its subject at the present day. It will deservedly maintain the place it has always had in the favor of the medical profession.—*Journ. of Nervous and Mental Disease*, April, 1877.

Such enormous advances have recently been made in our physiological knowledge, that what was perfectly new a year or two ago, looks now as if it had been received and established fact for years. In this encyclopædic way it is unrivalled. Here, as it seems to us, is the great value of the book; one is safe in sending a student to it for information on almost any given subject, perfectly certain of the fulness of information it will convey, and well satisfied of the accuracy with which it will there be found stated.—*London Med. Times and Gazette*, Feb. 17, 1877.

The merits of "Carpenter's Physiology" are so widely known and appreciated that we need only allude briefly to the fact that in the latest edition will be found a comprehensive embodiment of the results of recent physiological investigation. Care has been taken to preserve the practical character of the original work. In fact the entire work has been brought up to date, and bears evidence of the amount of labor that has been bestowed upon it by its distinguished editor, Mr. Henry Power. The American editor has made the latest additions, in order fully to cover the time that has elapsed since the last English edition.—*N. Y. Med. Journal*, Jan. 1877.

FOSTER (MICHAEL), M.D., F.R.S.,

Prof. of Physiology in Cambridge Univ., England.

TEXT-BOOK OF PHYSIOLOGY. Latest edition. In one handsome 12mo. vol. of over 800 pages, with 72 illustrations. Cloth, $3 00. (*Just Ready.*)

Dr. Foster has combined in this work the conflicting desiderata in all text-books—comprehensiveness, brevity, and clearness. After a careful perusal of the whole work we can confidently recommend it, both to the student and the practitioner, as being one of the best text-books on physiology extant.—*The London Lancet.*

LEHMANN'S MANUAL OF CHEMICAL PHYSIOLOGY. Translated from the German, with Notes and Additions, by J. CHESTON MORRIS, M.D. With illustrations on wood. In one octavo volume of 336 pages. Cloth, $2 25.

LEHMANN'S PHYSIOLOGICAL CHEMISTRY. Complete in two large octavo volumes of 1200 pages, with 200 illustrations; cloth, $6.

ATTFIELD (JOHN), Ph.D.,

Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, &c.

CHEMISTRY, GENERAL, MEDICAL, AND PHARMACEUTICAL;

Including the Chemistry of the U. S. Pharmacopœia. A Manual of the General Principles of the Science, and their Application to Medicine and Pharmacy. Eighth edition, revised by the author. In one handsome royal 12mo. volume of 700 pages, with illustrations. Cloth, $2 50; leather, $3 00. (*Now Ready.*)

We have repeatedly expressed our favorable opinion of this work, and on the appearance of a new edition of it, little remains for us to say, except that we expect this eighth edition to be as indispensable to us as the seventh and previous editions have been. While the general plan and arrangement have been adhered to, new matter has been added covering the observations made since the former edition. The present differs from the preceding one chiefly in these alterations and in about ten pages of useful tables added in the appendix.—*Am. Jour. of Pharmacy*, May, 1879.

A standard work like Attfield's Chemistry need only be mentioned by its name, without further comments. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. The author has bestowed arduous labor on the revision, and the extent of the information thus introduced may be estimated from the fact that the index contains three hundred new references relating to additional material.—*Druggists' Circular and Chemical Gazette*, May, 1879.

This very popular and meritorious work has now reached its eighth edition, which fact speaks in the highest terms in commendation of its excellence. It has now become the principal text-book of chemistry in all the medical colleges in the United States. The present edition contains such alterations and additions as seemed necessary for the demonstration of the latest developments of chemical principles, and the latest applications of chemistry to pharmacy. It is scarcely necessary for us to say that it exhibits chemistry in its present advanced state.—*Cincinnati Medical News*, April, 1879.

The popularity which this work has enjoyed is owing to the original and clear disposition of the facts of the science, the accuracy of the details, and the omission of much which freights many treatises heavily without bringing corresponding instruction to the reader. Dr. Attfield writes for students, and primarily for medical students; he always has an eye to the pharmacopœia and its official preparations; and he is continually putting the matter in the text so that it responds to the questions with which each section is provided. Thus the student learns easily, and can always refresh and test his knowledge.—*Med and Surg. Reporter*, April 19, '79.

We noticed only about two years and a half ago the publication of the preceding edition, and remarked upon the exceptionally valuable character of the work. The work now includes the whole of the chemistry of the pharmacopœia of the United States, Great Britain, and India.—*New Remedies*, May, 1879.

GREENE (WILLIAM H.), M.D.,

Demonstrator of Chemistry in Med. Dept., Univ. of Penna.

A MANUAL OF MEDICAL CHEMISTRY. For the Use of Students.

Based upon Bowman's Medical Chemistry. In one royal 12mo. volume of 312 pages. With illustrations. Cloth, $1 75. (*Now Ready.*)

It is well written, and gives the latest views on vital chemistry, a subject with which most physicians are not sufficiently familiar. To those who may wish to improve their knowledge in that direction, we can heartily recommend this work as being worthy of a careful perusal.—*Phila. Med. and Surg. Reporter*, April 24, 1880.

The little work before us is one which we think will be studied with pleasure and profit. The descriptions, though brief, are clear, and in most cases sufficient for the purpose. This book will, in nearly all cases, meet general approval.—*Am. Journ. of Pharmacy*, April, 1880.

CLASSEN (ALEXANDER),

Professor in the Royal Polytechnic School, Aix-la-Chapelle.

ELEMENTARY QUANTITATIVE ANALYSIS. Translated with

notes and additions by EDGAR F. SMITH, Ph.D., Assistant Prof. of Chemistry in the Towne Scientific School, Univ. of Penna. In one handsome royal 12mo. volume, of 324 pages, with illustrations; cloth, $2 00. (*Just Ready.*)

It is probably the best manual of an elementary nature extant, insomuch as its methods are the best. It teaches by examples, commencing with single determinations, followed by separations, and then advancing to the analysis of minerals and such products as are met with in applied chemistry. It is an indispensable book for students in chemistry.—*Boston Journ. of Chemistry*, Oct. 1878.

GALLOWAY (ROBERT), F.C.S.,

Prof. of Applied Chemistry in the Royal College of Science for Ireland, etc.

A MANUAL OF QUALITATIVE ANALYSIS. From the Fifth London Edition.

In one neat royal 12mo. volume, with illustrations; cloth, $2 75. (*Lately Issued.*)

REMSEN (IRA), M.D., Ph.D.,

Professor of Chemistry in the Johns Hopkins University, Baltimore.

PRINCIPLES OF THEORETICAL CHEMISTRY, with special reference

to the Constitution of Chemical Compounds. In one handsome royal 12mo. vol. of over 232 pages: cloth, $1 50. (*Just Issued.*)

BOWMAN'S INTRODUCTION TO PRACTICAL CHEMISTRY, INCLUDING ANALYSIS. Sixth American, from the sixth and revised London edition. With numerous illustrations. In one neat vol., royal 12mo., cloth, $2 25.

WÖHLER AND FITTIG'S OUTLINES OF ORGANIC CHEMISTRY. Translated with additions from the Eighth German Edition. By IRA REMSEN, M D., Ph D., Prof. of Chemistry and Physics in Williams College, Mass. In one volume, royal 12mo. of 550 pp., cloth, $3.

FOWNES (GEORGE), Ph.D.

A MANUAL OF ELEMENTARY CHEMISTRY; Theoretical and Practical.

Revised and corrected by HENRY WATTS, B.A., F.R.S., author of "A Dictionary of Chemistry," etc. With a colored plate, and one hundred and seventy-seven illustrations. A new American, from the twelfth and enlarged London edition. Edited by ROBERT BRIDGES, M.D. In one large royal 12mo. volume, of over 1000 pages; cloth, $2 75; leather, $3 25. (*Just Issued.*)

This work, inorganic and organic, is complete in one convenient volume. In its earliest editions it was fully up to the latest advancements and theories of that time. In its present form, it presents, in a remarkably convenient and satisfactory manner, the principles and leading facts of the chemistry of *to-day*. Concerning the manner in which the various subjects are treated, much deserves to be said, and mostly, too, in praise of the book. A review of such a work as *Fownes's Chemistry* within the limits of a book-notice for a medical weekly is simply out of the question.—*Cincinnati Lancet and Clinic*, Dec. 14, 1878.

When we state that, in our opinion, the present edition sustains in every respect the high reputation which its predecessors have acquired and enjoyed, we express therewith our full belief in its intrinsic value as a text-book and work of reference.—*Am. Journ. of Pharm.*, Aug. 1878.

The conscientious care which has been bestowed upon it by the American and English editors renders it still, perhaps, the best book for the student and the practitioner who would keep alive the acquisitions of his student days. It has, indeed, reached a somewhat formidable magnitude with its more than a thousand pages, but with less than this no fair representation of chemistry as it now is can be given. The type is small but very clear, and the sections are very lucidly arranged to facilitate study and reference.—*Med. and Surg. Reporter*, Aug 3, 1878.

The work is too well known to American students to need any extended notice; suffice it to say that the revision by the English editor has been faithfully done, and that Professor Bridges has added some fresh and valuable matter, especially in the inorganic chemistry. The book has always been a favorite in this country, and in its new shape bids fair to retain all its former *prestige*.—*Boston Jour. of Chemistry*, Aug. 1878.

It will be entirely unnecessary for us to make any remarks relating to the general character of Fownes' Manual. For over twenty years it has held *the* foremost place as a text-book, and the elaborate and thorough revisions which have been made from time to time leave little chance for any wide awake rival to step before it.—*Canadian Pharm. Jour.*, Aug 1878.

As a manual of chemistry it is without a superior in the language.—*Md. Med. Jour.*, Aug. 1878.

BLOXAM (C. L.),

Professor of Chemistry in King's College, London.

CHEMISTRY, INORGANIC AND ORGANIC.

From the Second London Edition. In one very handsome octavo volume, of 700 pages, with about 300 illustrations. Cloth, $4 00; leather, $5 00. (*Lately Issued.*)

We have in this work a complete and most excellent text-book for the use of schools, and can heartily recommend it as such.—*Boston Med. and Surg. Journ.*, May 28, 1874.

The above is the title of a work which we can most conscientiously recommend to students of chemistry. It is as easy as a work on chemistry could be made, at the same time that it presents a full account of that science as it now stands. We have spoken of the work as admirably adapted to the wants of students; it is quite as well suited to the requirements of practitioners who wish to review their chemistry, or have occasion to refresh their memories on any point relating to it. In a word, it is a book to be read by all who wish to know what is the chemistry of the present day.—*American Practitioner*, Nov. 1873.

It would be difficult for a practical chemist and teacher to find any material fault with this most admirable treatise. The author has given us almost a cyclopædia within the limits of a convenient volume, and has done so without penning the *useless* paragraphs too commonly making up a great part of the bulk of many cumbrous works. The progressive scientist is not disappointed when he looks for the record of new and valuable processes and discoveries, while the cautious conservative does not find its pages monopolized by uncertain theories and speculations. A peculiar point of excellence is the crystallized form of expression in which great truths are expressed in very short paragraphs. One is surprised at the brief space allotted to an important topic, and yet, after reading it, he feels that little, if any more should have been said. Altogether, it is seldom you see a text-book so nearly faultless.—*Cincinnati Lancet*, Nov. 1873.

CLOWES (FRANK), D.Sc., London.

Senior Science-Master at the High School, Newcastle-under-Lyme, etc.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS.

Specially adapted for Use in the Laboratories of Schools and Colleges and by Beginners. Second American from the Third and Revised English Edition. In one very handsome royal 12mo. volume of 372 pages, with 47 illustrations. Cloth, $2 50. (*Just Ready.*)

This is a valuable work for those about to commence chemistry, the more so as by its use they are simultaneously acquainted with the manipulation of chemical analysis, a method which is the most valuable to impart a thorough knowledge of chemistry. It is a very good little book, and will make for itself many warm friends and supporters. It treats the subject well and the tables are very clear and valuable.—*St Louis Med. and Surg. Journ.*, Mar. 1881.

This work is not only well adapted for use as a text-book in medical colleges, but is also one of the best that a practitioner can have for convenient reference and instruction in his library. As a rule, such volumes are too technical and abstruse for study without some didactic aid, but the volume presented is easy of comprehension, and will be of great value to college students and busy practitioners.—*N. Y. Am. Med. Bi-Weekly*, April 9, 1881.

The tables particularly demand praise, for they are admirably formed, both for convenience of reference and fulness of information. In short, we do not remember to have met with a book which could better serve the student as a guide to the systematic study of inorganic chemistry.—*Louisville Med. News*, March 12, 1881.

KNAPP'S TECHNOLOGY; or Chemistry Applied to the Arts and to Manufactures. With American additions by Prof. WALTER R. JOHNSON. In two very handsome octavo volumes, with 500 wood engravings, cloth, $6 00.

PARRISH (EDWARD),

Late Professor of Materia Medica in the Philadelphia College of Pharmacy.

A TREATISE ON PHARMACY. Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmaceutist. With many Formulæ and Prescriptions. Fourth Edition, thoroughly revised, by THOMAS S. WIEGAND. In one handsome octavo volume of 977 pages, with 280 illustrations; cloth, $5 50; leather, $6 50; half Russia, $7. (*Lately Issued.*)

Of Dr Parrish's great work on pharmacy it only remains to be said that the editor has accomplished his work so well as to maintain, in this fourth edition, the high standard of excellence which it had attained in previous editions, under the editorship of its accomplished author. This has not been accomplished without much labor, and many additions and improvements, involving changes in the arrangement of the several parts of the work, and the addition of much new matter. With the modifications thus effected it constitutes, as now presented, a compendium of the science and art indispensable to the pharmacist, and of the utmost value to every practitioner of medicine desirous of familiarizing himself with the pharmaceutical preparation of the articles which he prescribes for his patients.—*Chicago Med. Journ.*, July, 1874.

The work is eminently practical, and has the rare merit of being readable and interesting, while it preserves a strictly scientific character. The whole work reflects the greatest credit on author, editor and publisher. It will convey some idea of the liberality which has been bestowed upon its production when we mention that there are no less than 280 carefully executed illustrations. In conclusion, we heartily recommend the work, not only to pharmacists, but also to the multitude of medical practitioners who are obliged to compound their own medicines. It will ever hold an honored place on our own bookshelves.—*Dublin Med. Press and Circular*, Aug. 12, 1874.

We expressed our opinion of a former edition in terms of unqualified praise, and we are in no mood to detract from that opinion in reference to the present edition, the preparation of which has fallen into competent hands. It is a book with which no pharmacist can dispense, and from which no physician can fail to derive much information of value to him in practice.—*Pacific Med. and Surg. Journ.*, June, '74.

Perhaps one, if not the most important book upon pharmacy which has appeared in the English language has emanated from the transatlantic press. "Parrish's Pharmacy" is a well-known work on this side of the water, and the fact shows us that a really useful work never becomes merely local in its fame. Thanks to the judicious editing of Mr. Wiegand, the posthumous edition of "Parrish" has been saved to the public with all the mature experience of its author, and perhaps none the worse for a dash of new blood.—*Lond. Pharm. Journal*, Oct. 17, 1874.

GRIFFITH (ROBERT E.), M.D.

A UNIVERSAL FORMULARY, Containing the Methods of Preparing and Administering Officinal and other Medicines. The whole adapted to Physicians and Pharmaceutists. Third edition, thoroughly revised, with numerous additions, by JOHN M. MAISCH, Professor of Materia Medica in the Philadelphia College of Pharmacy. In one large and handsome octavo volume of about 800 pp., cl., $4 50; leather, $5 50. (*Lately Issued.*)

To the druggist a good formulary is simply indispensable, and perhaps no formulary has been more extensively used than the well-known work before us. Many physicians have to officiate, also, as druggists. This is true especially of the country physician, and a work which shall teach him the means by which to administer or combine his remedies in the most efficacious and pleasant manner, will always hold its place upon his shelf. A formulary of this kind is of benefit also to the city physician in largest practice.—*Cincinnati Clinic*, Feb. 21, 1874.

A more complete formulary than it is in its present form the pharmacist or physician could hardly desire. To the first some such work is indispensable, and it is hardly less essential to the practitioner who compounds his own medicines. Much of what is contained in the introduction ought to be committed to memory by every student of medicine. As a help to physicians it will be found invaluable, and doubtless will make its way into libraries not already supplied with a standard work of the kind.—*The American Practitioner*, Louisville, July, '74.

FARQUHARSON (ROBERT), M.D.,

Lecturer on Materia Medica at St. Mary's Hospital Medical School.

A GUIDE TO THERAPEUTICS AND MATERIA MEDICA. Second American edition, revised by the Author. Enlarged and adapted to the U. S. Pharmacopœia. By FRANK WOODBURY, M.D. In one neat royal 12mo. volume of 498 pages: cloth, $2 25. (*Just Ready.*)

The appearance of a new edition of this convenient and handy book in less than two years may certainly be taken as an indication of its usefulness. Its convenient arrangement, and its terseness, and, at the same time, completeness of the information given, make it a handy book of reference.—*Am. Journ of Pharmacy*, June, 1879.

This work contains in moderate compass such well-digested facts concerning the physiological and therapeutical action of remedies as are reasonably established up to the present time. By a convenient arrangement the corresponding effects of each article in health and disease are presented in parallel columns, not only rendering reference easier, but also impressing the facts more strongly upon the mind of the reader. The book has been adapted to the wants of the American student, and copious notes have been introduced, embodying the latest revision of the Pharmacopœia, together with the antidotes to the more prominent poisons, and such of the newer remedial agents as seemed necessary to the completeness of the work. Tables of weights and measures, and a good alphabetical index end the volume.—*Druggists' Circular and Chemical Gazette*, June, 1879.

It is a pleasure to think that the rapidity with which a second edition is demanded may be taken as an indication that the sense of appreciation of the value of reliable information regarding the use of remedies is not entirely overwhelmed in the cultivation of pathological studies, characteristic of the present day. This work certainly merits the success it has so quickly achieved.—*New Remedies*, July, '79.

CHRISTISON'S DISPENSATORY. With copious additions, and 213 large wood engravings. By R. EGLESFIELD GRIFFITH, M.D. One vol. 8vo., pp. 1000, cloth, $4 00.

CARPENTER'S PRIZE ESSAY ON THE USE OF ALCOHOLIC LIQUORS IN HEALTH AND DISEASE. New edition, with a Preface by D. F. CONDIE, M.D., and explanations of scientific words. In one neat 12mo. volume, pp. 178, cloth, 60 cents.

STILLE (*ALFRED*), *M.D., LL.D., and* MAISCH (*JOHN M.*), *Ph.D.*,
Prof. of Theory and Practice of Medicine and of Clinical Med. in Univ. of Pa.
Prof. of Mat. Med. and Bot. in Phila. Coll. Pharmacy, Secy. to the American Pharmaceutical Association.

THE NATIONAL DISPENSATORY: Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex. Second edition, thoroughly revised, with numerous additions. In one very handsome octavo volume of 1692 pages, with 239 illustrations. Extra cloth, $6 75; leather, raised bands, $7 50; half Russia, raised bands and open back, $8 25. (*Now Ready.*)

PREFACE TO THE SECOND EDITION.

The demand which has exhausted in a few months an unusually large edition of the National Dispensatory is doubly gratifying to the authors, as showing that they were correct in thinking that the want of such a work was felt by the medical and pharmaceutical professions, and that their efforts to supply that want have been acceptable. This appreciation of their labors has stimulated them in the revision to render the volume more worthy of the very marked favor with which it has been received. The first edition of a work of such magnitude must necessarily be more or less imperfect; and though but little that is new and important has been brought to light in the short interval since its publication, yet the length of time during which it was passing through the press rendered the earlier portions more in arrears than the later. The opportunity for a revision has enabled the authors to scrutinize the work as a whole, and to introduce alterations and additions wherever there has seemed to be occasion for improvement or greater completeness. The principal changes to be noted are the introduction of several drugs under separate headings, and of a large number of drugs, chemicals, and pharmaceutical preparations classified as allied drugs and preparations under the heading of more important or better known articles: these additions comprise in part nearly the entire German Pharmacopœia and numerous articles from the French Codex. All new investigations which came to the authors' notice up to the time of publication have received due consideration.

The series of illustrations has undergone a corresponding thorough revision. A number have been added, and still more have been substituted for such as were deemed less satisfactory.

The new matter embraced in the text is equal to nearly one hundred pages of the first edition. Considerable as are these changes as a whole, they have been accommodated by an enlargement of the page without increasing unduly the size of the volume.

While numerous additions have been made to the sections which relate to the physiological action of medicines and their use in the treatment of disease, great care has been taken to make them as concise as was possible without rendering them incomplete or obscure. The doses have been expressed in the terms both of troy weight and of the metrical system, for the purpose of making those who employ the Dispensatory familiar with the latter, and paving the way for its introduction into general use.

The Therapeutical Index has been extended by about 2250 new references, making the total number in the present edition about 6000.

The articles there enumerated as remedies for particular diseases are not only those which, in the authors' opinion, are curative, or even beneficial, but those also which have at any time been employed on the ground of popular belief or professional authority. It is often of as much consequence to be acquainted with the worthlessness of certain medicines or with the narrow limits of their power, as to know the well attested virtues of others and the conditions under which they are displayed. An additional value possessed by such an Index is, that it contains the elements of a natural classification of medicines, founded upon an analysis of the results of experience, which is the only safe guide in the treatment of disease.

This evidence of success, seldom paralleled, shows clearly how well the authors have met the existing needs of the pharmaceutical and medical professions. Gratifying as it must be to them, they have embraced the opportunity offered for a thorough revision of the whole work, striving to embrace within it all that might have been omitted in the former edition, and all that has newly appeared of sufficient importance during the time of its collaboration, and the short interval elapsed since the previous publication. After having gone carefully through the volume we must admit that the authors have labored faithfully, and with success, in maintaining the high character of their work as a compendium meeting the requirements of the day, to which one can safely turn in quest of the latest information concerning everything worthy of notice in connection with Pharmacy, Materia Medica, and Therapeutics.—*Am. Jour. of Pharmacy*, Nov. 1879.

It is with great pleasure that we announce to our readers the appearance of a *second* edition of the National Dispensatory. The total exhaustion of the first edition in the short space of six months, is a sufficient testimony to the value placed upon the work by the profession. It appears that the rapid sale of the first edition must have induced both the editors and the publisher to make preparations for a new edition immediately after the first had been issued, for we find a large amount of new matter added and a good deal of the previous text altered and improved, which proves that the authors do not intend to let the grass grow under their feet, but to keep the work up to the time.—*New Remedies*, Nov. 1879.

This is a great work by two of the ablest writers on materia medica in America. The authors have produced a work which, for accuracy and comprehensiveness, is unsurpassed by any work on the subject. There is no book in the English language which contains so much valuable information on the various articles of the materia medica. The work has cost the authors years of laborious study, but they have succeeded in producing a dispensatory which is not only *national*, but will be a lasting memorial of the learning and ability of the authors who produced it.—*Edinburgh Medical Journal*, Nov. 1879.

It is by far more international or universal than any other book of the kind in our language, and more comprehensive in every sense.—*Pacific Med. and Surg. Journ.*, Oct. 1579.

The National Dispensatory is beyond dispute the very best authority. It is throughout complete in all the necessary details, clear and lucid in its explanations, and replete with references to the most recent writings, where further particulars can be obtained, if desired. Its value is greatly enhanced by the extensive indices—a general index of materia medica, etc., and also an index of therapeutics. It would be a work of supererogation to say more about this well-known work. No practising physician can afford to be without the National Dispensatory.—*Canada Med. and Surg. Journ.*, Feb. 1880.

STILLÉ (*ALFRED*), *M. D.*,

Professor of Theory and Practice of Medicine in the University of Penna.

THERAPEUTICS AND MATERIA MEDICA; a Systematic Treatise

on the Action and Uses of Medicinal Agents, including their Description and History. Fourth edition, revised and enlarged. In two large and handsome 8vo. vols. of about 2000 pages. Cloth, $10; leather, $12; half Russia, $13. (*Lately Issued.*)

It is unnecessary to do much more than to announce the appearance of the fourth edition of this well known and excellent work.—*Brit. and For. Med.-Chir. Review*, Oct 1875.

For all who desire a complete work on therapeutics and materia medica for reference, in cases involving medico-legal questions, as well as for information concerning remedial agents, Dr. Stillé's is "*par excellence*" the work. Being out of print, by the exhaustion of former editions, the author has laid the profession under renewed obligations, by the careful revision, important additions, and timely reissuing a work not exactly supplemented by any other in the English language, if in any language. The mechanical execution handsomely sustains the well-known skill and good taste of the publisher.—*St. Louis Med. and Surg. Journal*, Dec. 1874.

From the publication of the first edition "Stillé's Therapeutics" has been one of the classics; its absence from our libraries would create a vacuum which could be filled by no other work in the language, and its presence supplies, in the two volumes of the present edition, a whole cyclopædia of therapeutics.—*Chicago Medical Journal*, Feb. 1875.

The rapid exhaustion of three editions and the universal favor with which the work has been received by the medical profession, are sufficient proof of its excellence as a repertory of practical and useful information for the physician. The edition before us fully sustains this verdict, as the work has been carefully revised and in some portions rewritten, bringing it up to the present time by the admission of chloral and croton-chloral, nitrite of amyl, bichloride of methylene, methylic ether, lithium compounds, gelseminum, and other remedies.—*Am. Journ. of Pharmacy*, Feb. 1875.

We can hardly admit that it has a rival in the multitude of its citations and the fulness of its research into clinical histories, and we must assign it a place in the physician's library; not, indeed, as fully representing the present state of knowledge in pharmacodynamics, but as by far the most complete treatise upon the clinical and practical side of the question.—*Boston Med. and Surg. Journal*, Nov. 5, 1874.

CORNIL (*V.*), *Prof. in the Faculty of Med., Paris.* AND RANVIER (*L.*), *Prof. in the College of France.*

MANUAL OF PATHOLOGICAL HISTOLOGY. Translated, with

Notes and Additions, by E. O. SHAKESPEARE, M.D., Pathologist and Ophthalmic Surgeon to Philada. Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in Univ. of Penna., and by HENRY C. SIMES, M.D., Demonstrator of Pathological Histology in the Univ. of Pa. In one very handsome octavo volume of over 700 pages, with over 350 illustrations. Cloth, $5 50; leather, $6 50; half Russia, $7. (*Just Ready.*)

The work of Cornil and Ranvier is so well known as a lucid and accurate text-book on its important subject, that no apology is needed in presenting a translation of it to the American profession. It is only necessary to say that the labors of Drs. Shakespeare and Simes have been by no means confined to the task of rendering the work into English. As it appeared in France, in successive portions, between 1868 and 1876, a part of it, at least, was somewhat in arrears of the present state of science, while the diffuseness of other portions rendered condensation desirable. The translators have, therefore, sought to bring the work up to the day, and, at the same time, to reduce it in size, as far as practicable, without impairing its completeness. These changes will be found throughout the volume, the most extensive being in the sections devoted to Sarcoma, Carcinoma, Tuberculosis, the Bloodvessels, the Mammæ, and the classification of tumors. Corresponding modifications have been made in the very extensive and beautiful series of illustrations, and every care has been taken in the typographical execution to render it one of the most attractive volumes which have issued from the American press.

We have no hesitation in cordially recommending the English translation of Cornil & Ranvier's "Pathological Histology" as the best work of the kind in any language, and as giving to its readers a trustworthy guide in obtaining a broad and solid basis for the appreciation of the practical bearings of pathological anatomy.—*Am. Journ. of Med. Sciences*, April, 1880.

This important work, in its American dress, is a welcome offering to all students of the subjects which it treats. The great mass of material is arranged naturally and comprehensively. The classification of tumors is clear and full, so far as the subject admits of definition, and this one chapter is worth the price of the book. The illustrations are copious and well chosen. Without the slightest hesitation, the translators deserve honest thanks for placing this indispensable work in the hands of American students.—*Phila. Med. Times*, April 24, 1880

This volume we cordially commend to the profession. It will prove a valuable, almost necessary, addition to the libraries of students who are to be physicians, and to the libraries of students who are physicians.—*American Practitioner*, June, 1880.

Their book is not a collection of the work of others, but has been written in the laboratory beside the microscope. It bears the marks of personal knowledge and investigation upon every page, controlled by and controlling the work of others. . . . In short, its translation has made it the best work in pathology attainable in our language, one that every student certainly ought to have.—*Archives of Medicine*, April, 1880.

This work, in the original, has for years past occupied a prominent place in the library of French pathologists, as we should naturally be led to believe from the reputation of the distinguished authors. Now that it has been presented to the English student for the first time, it will be perused with unusual interest. The illustrations are by no means the least valuable part of the work. Indispensable as they are to any work of this nature, in the work before us the artist has succeeded in producing cuts which will prove unusually valuable to the reader. The translation is well done, and gives evidence throughout the volume that it was made by a person thoroughly conversant with the subject.—*N. Y. Med. Gazette*, Feb. 28, 1880.

GLUGE'S ATLAS OF PATHOLOGICAL HISTOLOGY. Translated, with Notes and Additions, by JOSEPH LEIDY, M. D. In one volume, very large imperial quarto, with 320 copper-plate figures, plain and colored, cloth. $4 00.

PAVY'S TREATISE ON THE FUNCTION OF DIGESTION: its Disorders and their Treatment. From the second London edition. In one handsome volume, small octavo, cloth, $2 00.

FENWICK (SAMUEL), M.D.,
Assistant Physician to the London Hospital.

THE STUDENT'S GUIDE TO MEDICAL DIAGNOSIS.

From the Third Revised and Enlarged English Edition With eighty-four illustrations on wood. In one very handsome volume, royal 12mo., cloth, $2 25. (*Just Issued.*)

GREEN (T. HENRY), M.D.,
Lecturer on Pathology and Morbid Anatomy at Charing-Cross Hospital Medical School, etc.

PATHOLOGY AND MORBID ANATOMY.

Fourth American, from the Fifth Enlarged and Revised English Edition. In one very handsome octavo volume of about 350 pages, with 139 fine engravings; cloth, $2 25. (*Just Ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

In preparing the fifth edition of my Text-book on Pathology and Morbid Anatomy, I have again added much new matter, with the object of making the work a more complete guide for the student. All the chapters have been carefully revised, some alterations have been made in the arrangement of the work, and an addition has been made to the number of wood-cuts. The new wood cuts, as in previous editions, have been drawn by Mr. Collings from my own microscopical preparations.

BRISTOWE (JOHN SYER), M.D., F.R.C.P.,
Physician and Joint Lecturer on Medicine, St. Thomas's Hospital.

A TREATISE ON THE PRACTICE OF MEDICINE.

Second American edition, revised by the Author. Edited, with Additions, by JAMES H. HUTCHINSON, M.D., Physician to the Penna. Hospital. In one handsome octavo volume of nearly 1200 pages. With illustrations. Cloth, $5 00; leather, $6 00; half Russia, $6 50. (*Now Ready.*)

The second edition of this excellent work, like the first, has received the benefit of Dr. Hutchinson's annotations, by which the phases of disease which are peculiar to this country are indicated, and thus a treatise which was intended for British practitioners and students is made more practically useful on this side of the water. We see no reason to modify the high opinion previously expressed with regard to Dr. Bristowe's work, except by adding our appreciation of the careful labors of the author in following the lateral growth of medical science. The chapter on diseases of the skin and of the nervous system, with a new one on insanity compiled from the best sources outside of the author's own long experience, and the valuable portion relating to general pathology, aid greatly in completing an exceptionally good book for purposes of reference and instruction.—*Boston Medical and Surgical Journal*, February, 1880.

What we said of the first edition, we can, with increased emphasis, repeat concerning this: "Every page is characterized by the utterances of a thoughtful man. What has been said, has been well said, and the book is a fair reflex of all that is *certainly known* on the subjects considered."—*Ohio Med. Recorder*, Jan. 7, 1880.

The views of the author are expressed with precision and sufficient promptness to impress the student with the weight of his authority; and should the medical professor differ on any subject from his doctrine, he will need to find strong arguments to carry his class to the opposite conclusion.—*N. O. Med. and Surg. Journ.*, Feb. 1880.

The reader will find every conceivable subject connected with the practice of medicine ably presented, in a style at once clear, interesting, and concise. The additions made by Dr. Hutchinson are appropriate and practical, and greatly add to its usefulness to American readers.—*Buffalo Med. and Surg. Journ.*, March, 1880.

We regard it as an excellent work for students and for practitioners. It is clearly written, the author's style is attractive, and it is especially to be commended for its excellent exposition of the pathological and clinical phenomena of disease.—*St. Louis Clin. Record*, Feb. 1880.

HABERSHON (S. O.) M.D.
Senior Physician to and late Lecturer on the Principles and Practice of Medicine at Guy's Hospital, etc.

ON THE DISEASES OF THE ABDOMEN, COMPRISING THOSE

of the Stomach, and other parts of the Alimentary Canal, Œsophagus, Cæcum, Intestines, and Peritoneum. Second American, from the third enlarged and revised English edition. With illustrations. In one handsome octavo volume of over 500 pages. Cloth, $3 50. (*Now Ready.*)

This valuable treatise on diseases of the stomach and abdomen has been out of print for several years, and is therefore not so well known to the profession as it deserves to be. It will be found a cyclopædia of information, systematically arranged, on all diseases of the alimentary tract, from the mouth to the rectum. A fair proportion of each chapter is devoted to symptoms, pathology, and therapeutics. The present edition is fuller than former ones in many particulars, and has been thoroughly revised and amended by the author. Several new chapters have been added, bringing the work fully up to the times, and making it a volume of interest to the practitioner in every field of medicine and surgery. Perverted nutrition is in some form associated with all diseases we have to combat, and we need all the light that can be obtained on a subject so broad and general. Dr Habershon's work is one that every practitioner should read and study for himself.—*N. Y. Med. Journ.*, April, 1879.

LA ROCHE ON YELLOW FEVER, considered in its Historical, Pathological, Etiological, and Therapeutical Relations. In two large and handsome octavo volumes of nearly 1500 pp., cloth. $7 00

STOKES' LECTURES ON FEVER. Edited by JOHN WILLIAM MOORE, M.D., Assistant Physician to the Cork Street Fever Hospital. In one neat 8vo volume, cloth, $2 00.

HOLLAND'S MEDICAL NOTES AND REFLECTIONS. 1 vol. 8vo., pp. 500, cloth. $3 50.

BARLOW'S MANUAL OF THE PRACTICE OF MEDICINE. With Additions by D. F. CONDIE, M.D. 1 vol 8vo., pp. 600, cloth. $2 50.

TODD'S CLINICAL LECTURES ON CERTAIN ACUTE DISEASES. In one neat octavo volume, of 330 pp. cloth. $2 50.

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Med College, N Y.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; designed for the use of Students and Practitioners of Medicine. Fifth edition, entirely rewritten and much improved. In one large and closely printed octavo volume of 1153 pp. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7. (*Just Ready.*)

Practically, this edition is a new work; for so many additions and changes have been made that one well acquainted with previous editions would hardly recognize this as an old friend. The size of the volume is somewhat increased. An entire new section and several new chapters have been added. It is universally conceded that no text book upon this subject was ever published in this country that can at all compare with it. It has long been at the very head of American text-book literature, and there can be no doubt but that it will be many years before it yields the place to others.—*Nashville Journ. of Med. and Surg*, Feb. 1881.

"Flint's Practice" is recognized to be a standard treatise of high rank upon the principles and the practice of medicine wherever the English language is read. The opinions everywhere reveal the man of extensive experience, diligent study, calm judgment, and unbiased criticism. The work should be in the hands of every practitioner.—*New York Med. Record*, Feb. 26, 1881.

This edition differs so much from all previous editions, on account of the revisions eliminations, amplifications, and additions, so conspicuously manifest, that no one can be said to possess the actual views of the author on the practice of medicine, unless he becomes the possessor of this volume It is certainly the only American work on this subject which can be unreservedly recommended, and the only one which does justice to American authors, observers, and practitioners.—*Gaillard's Medical Journal*, Feb. 1881.

The style and character of this work are too well known to the profession to require an introduction. For a number of years this volume has occupied a leading position as a text-book in the majority of medical schools, and the high position accorded to it in the past is a guarantee of a hearty welcome in this new edition. The book may be said to represent the present state of the science of medicine as now understood and taught. It is a safe guide to students and practitioners of medicine.—*Maryland Medical Journal*, March 1, 1881.

A marked feature of value in the new edition of Flint is the condensed section on morbid anatomy prefacing each subject discussed, and the very good prefix on general pathology, chapters all of them written, as the author states in his preface, by Dr. Wm. H. Welch, lecturer on pathological histology in Bellevue Hospital Medical College. Dr. Welch has done his part of the work to all acceptation.—*Cincinnati Lancet and Clinic*, March 12, 1881.

The author has, in this edition, revised and rewritten a great part and made it accord with the more advanced ideas which have been developed within the past few years. He is the more fitted to do so, as he is actively engaged in his profession, and can make deductions, not from the work of others, but from his own labors. It is a treatise which every American physician should have upon his table, and which he should consult on occasions when his leisure permits him to do so.—*St. Louis Med. and Surg. Journal*, March, 1881.

BY THE SAME AUTHOR.

CLINICAL MEDICINE; a Systematic Treatise on the Diagnosis and Treatment of Diseases. Designed for Students and Practitioners of Medicine. In one large and handsome octavo volume of 795 pages; cloth, $4 50; leather, $5 50; half Russia, $6. (*Now Ready.*)

The eminent teacher who has written the volume under consideration has recognized the needs of the American profession, and the result is all that we could wish. The style in which it is written is peculiarly the author's; it is clear and forcible, and marked by those characteristics which have rendered him one of the best writers and teachers this country has ever produced. We have not space for so full a consideration of this remarkable work as we would desire.—*S. Louis Clin. Record*, Oct. 1879.

It is here that the skill and learning of the great clinician are displayed He has given us a storehouse of medical knowledge, excellent for the student, convenient for the practitioner, the result of a long life of the most faithful clinical work, collected by an energy as vigilant and systematic as untiring, and weighed by a judgment no less clear than his observation is close.—*Archives of Medicine*, Dec. 1879

To give an adequate and useful conspectus of the extensive field of modern clinical medicine is a task of no ordinary difficulty; but to accomplish this consistently, with brevity and clearness, the different subjects and their several parts receiving the attention which, relatively to their importance, medical opinion claims for them, is still more difficult. This task we feel bound to say has been executed with more than partial success by Dr Flint, whose name is already familiar to students of advanced medicine in this country as that of the author of two works of great merit on special subjects, and of numerous papers, exhibiting much originality and extensive research.—*The Dublin Journal*, Dec. 1879.

There is every reason to believe that this book will be well received. The active practitioner is frequently in need of some work that will enable him to obtain information in the diagnosis and treatment of cases with comparatively little labor. Dr. Flint has the faculty of expressing himself clearly, and at the same time so concisely as to enable the searcher to traverse the entire ground of his search, and at the same time obtain all that is essential, without plodding through interminable space.—*N. Y. Med. Jour.*, Nov.

The great object is to place before the reader the latest observations and experience in diagnosis and treatment. Such a work is especially valuable to students. It is complete in its special design, and yet so condensed, that he can by its aid, keep up with the lectures on practice without neglecting other branches. It will not escape the notice of the practitioner that such a work is most valuable in culling points in diagnosis and treatment in the intervals between the daily rounds of visits since he can in a few minutes refresh his memory, or learn the latest advance in the treatment of diseases which demand his instant attention.—*Cincinnati Lancet and Clinic*, Oct. 25, 1879.

BY THE SAME AUTHOR.

ESSAYS ON CONSERVATIVE MEDICINE AND KINDRED TOPICS. In one very handsome royal 12mo. volume. Cloth, $1 38. (*Just Issued.*)

DAVIS'S CLINICAL LECTURES ON VARIOUS IMPORTANT DISEASES; being a collection of the Clinical Lectures delivered in the Medical Wards of Mercy Hospital, Chicago. Edited by FRANK H DAVIS, M.D. Second edition, enlarged. In one handsome royal 12mo. volume. Cloth, $1 75.

THE CYCLOPÆDIA OF PRACTICAL MEDICINE: comprising Treatises on the Nature and Treatment of Diseases, Materia Medica and Therapeutics, Diseases of Women and Children, Medical Jurisprudence, etc. etc. By DUNGLISON, FORBES, TWEEDIE, and CONOLLY. In four large super-royal octavo volumes, of 3254 double-columned pages, strongly and handsomely bound in leather, $15; cloth, $11

STURGES'S INTRODUCTION TO THE STUDY OF CLINICAL MEDICINE. Being a Guide to the Investigation of Disease. In one handsome 12mo volume, cloth, $1 25. (*Lately Issued.*)

RICHARDSON (BENJ. W.), M.D., F.R.S., M.A., LL.D., F.S.A.,
Fellow of the Royal College of Physicians, London.

PREVENTIVE MEDICINE. In one octavo volume of about 500 pages.
(*In Press.*)

The immense strides taken by medical science during the last quarter of a century have had no more conspicuous field of progress than the causation of disease. Not only has this led to marked advance in therapeutics, but it has given rise to a virtually new department of medicine—the prevention of disease—more important, perhaps, in its ultimate results than even the investigation of curative processes. Yet thus far there has been no attempt to gather into a systematic and intelligible shape the accumulation of knowledge thus far acquired on this most interesting subject. Fortunately, the task has been at last undertaken by a writer who of all others is, perhaps, best qualified for its performance, and the result of his labors can hardly fail to mark an epoch in the history of medical science. The plan adopted for the execution of this novel design can best be explained in his own words:—

"With the object here expressed I write this volume. I have nothing to say in it that has any relation to the cure of disease, but I base it nevertheless on the curative side of medical learning. In other words, I trace the diseases from their actual representation as they exist before us, in their natural progress after their birth, as far as I am able, back to their origins, and try to seek the conditions out of which they spring. Thereupon I endeavor further to analyze those conditions, to see how far they are removable and how far they are avoidable."

WOODBURY (FRANK), M.D.,
Physician to the German Hospital, Philadelphia, late Chief Assist. to Med. Clinic, Jeff. College Hospital, etc.

A HANDBOOK OF THE PRINCIPLES AND PRACTICE OF MEDICINE; for the use of Students and Practitioners. Based upon Husband's Handbook of Practice. In one neat volume, royal 12mo. (*Preparing.*)

FOTHERGILL (J. MILNER), M.D. Edin., M.R.C.P. Lond.,
Asst. Phys. to the West Lond. Hosp.; Asst. Phys. to the City of Lond. Hosp., etc.

THE PRACTITIONER'S HANDBOOK OF TREATMENT; Or, the Principles of Therapeutics. Second edition, revised and enlarged. In one very neat octavo volume of about 650 pages. Cloth, $4 00; very handsome half Russia, $5 50. (*Just Ready.*)

The junior members of the profession will find in it a work that should not only be read, but carefully studied. It will assist them in the proper selection and combination of therapeutical agents best adapted to each case and condition, and enable them to prescribe intelligently and successfully. To do full justice to a work of this scope and character will be impossible in a review of this kind. The book itself must be read to be fully appreciated. —*St. Louis Courier of Medicine*, Nov. 1880.

The author merits the thanks of every well-educated physician for his efforts toward rationalizing the treatment of diseases upon the scientific basis of physiology. Every chapter, every line, has the impress of a master hand, and while the work is thoroughly scientific in every particular, it presents to the thoughtful reader all the charms and beauties of a well-written novel. No physician can well afford to be without this valuable work, for its originality makes it fill a niche in medical literature hitherto vacant.—*Nashville Journ. of Med. and Surg.*, Oct. 1880.

Throughout the work, while room is left for difference of opinion in matters of detail, the main courses of treatment are so carefully founded on well-established principles, that no essential difference is felt to be possible. The closing chapter contains much concentrated worldly wisdom; and, if carefully read, digested, and assimilated, will, in many an emergency, stand the young medical man in good stead.—*Lond. Med. Record*, Oct. 12, 1880.

FINLAYSON (JAMES), M.D.,
Physician and Lecturer on Clinical Medicine in the Glasgow Western Infirmary, etc.

CLINICAL DIAGNOSIS; A Handbook for Students and Practitioners of Medicine. In one handsome 12mo. volume, of 546 pages, with 85 illustrations. Cloth, $2 63. (*Just Issued.*)

The book is an excellent one, clear, concise, convenient, practical. It is replete with the very knowledge the student needs when he quits the lecture-room and the laboratory for the ward and sick-room, and does not lack in information that will meet the wants of experienced and older men.—*Phila. Med. Times*, Jan. 4, 1879.

This is one of the really useful books. It is attractive from preface to the final page, and ought to be given a place on every office table, because it contains in a condensed form all that is valuable in semeiology and diagnostics to be found in bulkier volumes, and because in its arrangement and complete index, it is unusually convenient for quick reference in any emergency that may come upon the busy practitioner. —*N. C. Med. Journ.*, Jan. 1879.

WATSON (THOMAS), M.D., &c.

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC. Delivered at King's College, London. A new American, from the Fifth revised and enlarged English edition. Edited, with additions, and several hundred illustrations, by HENRY HARTSHORNE, M.D., Professor of Hygiene in the University of Pennsylvania. In two large and handsome 8vo. vols. Cloth, $9 00; leather, $11 00. (*Lately Published.*)

HARTSHORNE (HENRY), M.D.,
Professor of Hygiene in the University of Pennsylvania

ESSENTIALS OF THE PRINCIPLES AND PRACTICE OF MEDICINE. A handy-book for Students and Practitioners. Fourth edition, revised and improved. With about one hundred illustrations. In one handsome royal 12mo. volume, of about 550 pages, cloth, $2 63; half bound, $2 88. (*Lately Issued.*)

REYNOLDS (J. RUSSELL), M.D.,

Prof. of the Principles and Practice of Medicine in Univ. College, London.

A SYSTEM OF MEDICINE. WITH NOTES AND ADDITIONS BY HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Penna. In three large and handsome octavo volumes, containing 3052 closely printed double-columned pages, with numerous illustrations. *Sold only by subscription.* Price per vol., in cloth, $5.00; in sheep, $6.00: half Russia, raised bands, $6.50. Per set in cloth, $15; sheep, $18; half Russia, $19.50

VOLUME I. (*just ready*) contains GENERAL DISEASES and DISEASES OF THE NERVOUS SYSTEM.
VOLUME II. (*just ready*) contains DISEASES OF RESPIRATORY and CIRCULATORY SYSTEMS.
VOLUME III. (*just ready*) contains DISEASES OF THE DIGESTIVE and BLOOD GLANDULAR SYSTEMS, OF THE URINARY ORGANS, OF THE FEMALE REPRODUCTIVE SYSTEM, and OF THE CUTANEOUS SYSTEM.

Reynolds's SYSTEM OF MEDICINE, recently completed, has acquired, since the first appearance of the first volume, the well-deserved reputation of being the work in which modern British medicine is presented in its fullest and most practical form. This could scarce be otherwise in view of the fact that it is the result of the collaboration of the leading minds of the profession, each subject being treated by some gentleman who is regarded as its highest authority—as for instance, Diseases of the Bladder by Sir HENRY THOMPSON, Malpositions of the Uterus by GRAILY HEWITT, Insanity by HENRY MAUDSLEY, Consumption by J. HUGHES BENNET, Diseases of the Spine by CHARLES BLAND RADCLIFFE, Pericarditis by FRANCIS SIBSON, Alcoholism by FRANCIS E. ANSTIE, Renal Affections by WILLIAM ROBERTS, Asthma by HYDE SALTER, Cerebral Affections by H CHARLTON BASTIAN, Gout and Rheumatism by ALFRED BARING GARROD, Constitutional Syphilis by JONATHAN HUTCHINSON, Diseases of the Stomach by WILSON FOX, Diseases of the Skin by BALMANNO SQUIRE, Affections of the Larynx by MORELL MACKENZIE, Diseases of the Rectum by BLIZARD CURLING, Diabetes by LAUDER BRUNTON, Intestinal Diseases by JOHN SYER BRISTOWE, Catalepsy and Somnambulism by THOMAS KING CHAMBERS, Apoplexy by J. HUGHLINGS JACKSON, Angina Pectoris by Professor GAIRDNER, Emphysema of the Lungs by Sir WILLIAM JENNER, etc. etc. All the leading schools in Great Britain have contributed their best men in generous rivalry, to build up this monument of medical science. St. Bartholomew's, Guy's, St Thomas's, University College, St Mary's in London, while the Edinburgh, Glasgow, and Manchester schools are equally well represented, the Army Medical School at Netley, the military and naval services, and the public health boards. That a work conceived in such a spirit, and carried out under such auspices should prove an indispensable treasury of facts and experience, suited to the daily wants of the practitioner, was inevitable, and the success which it has enjoyed in England, and the reputation which it has acquired on this side of the Atlantic, have sealed it with the approbation of the two pre-eminently practical nations.

Its large size and high price having kept it beyond the reach of many practitioners in this country who desire to possess it, a demand has arisen for an edition at a price which shall render it accessible to all. To meet this demand the present edition has been undertaken. The five volumes and five thousand pages of the original have by the use of a smaller type and double columns, been compressed into three volumes of over three thousand pages, clearly and handsomely printed, and offered at a price which renders it one of the cheapest works ever presented to the American profession.

But not only is the American edition more convenient and lower priced than the English; it is also better and more complete. Some years having elapsed since the appearance of a portion of the work, additions are required to bring up the subjects to the existing condition of science. Some diseases, also, which are comparatively unimportant in England, require more elaborate treatment to adapt the articles devoted to them to the wants of the American physician; and there are points on which the received practice in this country differs from that adopted abroad. The supplying of these deficiencies has been undertaken by HENRY HARTSHORNE, M.D., late Professor of Hygiene in the University of Pennsylvania, who has endeavored to render the work fully up to the day, and as useful to the American physician as it has proved to be to his English brethren. The number of illustrations has also been largely increased, and no effort spared to render the typographical execution unexceptionable in every respect.

Really too much praise can scarcely be given to this noble book. It is a cyclopædia of medicine written by some of the best men of Europe. It is full of useful information such as one finds frequent need of in one's daily work As a book of reference it is invaluable. It is up with the times. It is clear and concentrated in style, and its form is worthy of its famous publisher.—*Louisville Med. News*, Jan. 31, 1880.

"Reynolds' System of Medicine" is justly considered the most popular work on the principles and practice of medicine in the English language The contributors to this work are gentlemen of well-known reputation on both sides of the Atlantic. Each gentleman has striven to make his part of the work as practical as possible, and the information contained is such as is needed by the busy practitioner.—*St Louis Med. and Surg. Journ.*, Jan. '80.

Dr. Hartshorne has made ample additions and revisions, all of which give increased value to the volume, and render it more useful to the American practitioner There is no volume in English medical lite more valuable, and every purchaser will, on becoming familiar with it, congratulate himself on the possession of this vast storehouse of information, in regard to so many of the subjects with which he should be familiar —*Gaillard's Med. Journ.*, Feb. 1880

There is no medical work which we have in times past more frequently and fully consulted when perplexed by doubts as to treatment, or by having unusual or apparently inexplicable symptoms presented to us than "Reynolds' System of Medicine." Among its contributors are gentlemen who are as well known by reputation upon this side of the Atlantic as in Great Britain, and whose right to speak with authority upon the subjects about which they have written, is recognized the world over. They have evidently striven to make their essays as practical as possible, and while these are sufficiently full to entitle them to the name of monographs, they are not loaded down with such an amount of detail as to render them wearisome to the general reader. In a word, they contain just that kind of information which the busy practitioner frequently finds himself in need of. In order that any deficiencies may be supplied, the publishers have committed the preparation of the book for the press to Dr. Henry Hartshorne, whose judicious notes distributed throughout the volume afford abundant evidence of the thoroughness of the revision to which he has subjected it.—*Am. Jour. Med. Sciences*, Jan. 1880.

BARTHOLOW (ROBERTS), A M., M.D., LL.D.

Prof. of Materia Medica and General Therapeutics in the Jeff. Med. Coll. of Phila., etc.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATION TO MEDICINE.

In one very handsome 8vo. volume of about 300 pages, with numerous illustrations. (*Just ready.*)

The constantly increasing therapeutic use of electricity, and the absence of a concise guide suited to the wants of the general practitioner, have induced the author to prepare the present volume. His object has been to present the most advanced state of existing knowledge in a form divested of unnecessary technicalities, keeping constantly in view the practical needs of the student and physician.

As the volume is founded upon a course of lectures delivered in the Jefferson Medical College during 1880, its adaptation to its purpose is insured. Dr. Bartholow's power of lucid exposition is well known, and is particularly desirable in a subject such as this, treated from the standpoint of the general practitioner and not of the specialist.

MITCHELL (S. WEIR), M.D.,

Phys. to Orthopædic Hospital and the Infirmary for Dis. of the Nervous System, Phila., &c. etc.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, ESPECIALLY IN WOMEN.

In one very handsome 12mo. volume of about 250 pages, with five lithographic plates. Cloth, $1 75 (*Just Ready*)

The life-long devotion of the author to the subjects discussed in this volume has rendered it eminently desirable that the results of his labors should be embodied for the benefit of those who may experience the difficulties connected with the treatment of this class of disease. Many of these lectures are fresh studies of hysterical affections; others treat of the modifications his views have undergone in regard to certain forms of treatment, while, throughout the whole work he has been careful to keep in view the practical lessons of his cases. The scope of the volume may be gathered from the following

CONDENSED SUMMARY OF CONTENTS.

LECTURE I.—The Paralyses of Hysteria. II. Hysterical Motor Ataxia.—Hysterical Paresis. III. Mimicry of Disease. IV. Mimicry of Disease. V. Unusual Forms of Spasmodic Affections in Women. VI. Tremor—Chronic Spasms. VII. Chorea of Childhood. VIII. Habit Chorea. IX. Disorders of Sleep in Nervous or Hysterical Persons. X. Vaso Motor and Respiratory Disorders in the Nervous or Hysterical. XI. Hysterical Aphonia. XII. Gastro Intestinal Disorders of Hysteria. XIII. The Treatment of Nervous Exhaustion and Hysteria by Seclusion, Rest, Massage, Electricity, and Full Feeding.

HAMILTON (ALLAN McLANE), M.D.,

Attending Physician at the Hospital for Epileptics and Paralytics, Blackwell's Island, N.Y., and at the Out-Patients' Department of the New York Hospital.

NERVOUS DISEASES; THEIR DESCRIPTION AND TREATMENT.

In one handsome octavo volume of 512 pages, with 53 illus.; cloth, $3 50. (*Lately Issued.*)

CLINICAL OBSERVATIONS ON FUNCTIONAL NERVOUS DISORDERS By C. HANDFIELD JONES M.D., Physician to St. Mary's Hospital, &c. Second American Edition. In one handsome octavo volume of 348 pages, cloth, $3 25.

MORRIS (MALCOLM), M.D.,

Joint Lecturer on Dermatology, St. Mary's Hospital Med. School.

SKIN DISEASES, Including their Definitions, Symptoms, Diagnosis, Prognosis, Morbid Anatomy, and Treatment.

A Manual for Students and Practitioners. In one 12mo. volume of over 300 pages. With illustrations. Cloth, $1 75. (*Now Ready.*)

To physicians who would like to know something about skin diseases, so that when a patient presents himself for relief they can make a correct diagnosis and prescribe a rational treatment, we unhesitatingly recommend this little book of Dr. Morris. The affections of the skin are described in a terse, lucid manner, and their several characteristics so plainly set forth that diagnosis will be easy. The treatment in each case is such as the experience of the most eminent dermatologists advise.—*Cincinnati Medical News*, April, 1880.

This is emphatically a learner's book; for we can safely say, so far as our judgment goes, that in the whole range of medical literature of a like scope, there is no book which for clearness of expression and methodical arrangement is better adapted to promote a rational conception of dermatology, a branch confessedly difficult and perplexing to the beginner.—*St. Louis Courier of Medicine*, April, 1880.

The author of this manual has evidently a full and intimate acquaintance with the literature of dermatology, and with the most recent developments and appliances of cutaneous medicine. He has produced a plain, practical book, by aid of which, who so chooses may train his eye to the recognition of light but significant differences. The descriptions are neither too vague nor over-refined; the directions for treatment are clear and succinct.—*London Brain*, April, 1880.

The author's task has been well done and has produced one of the best recent works upon the difficult subject of which it treats; there is no work published which gives a better view of the elementary facts and principles of dermatology.—*New Orleans Medical and Surgical Journal*, April, 1880.

FOX (TILBURY), M.D., F.R.C.P., and T. C. FOX, B.A., M.R.C.S.,

Physician to the Department for Skin Diseases, University College Hospital.

EPITOME OF SKIN DISEASES. WITH FORMULÆ.

FOR STUDENTS AND PRACTITIONERS. Second edition, thoroughly revised and greatly enlarged. In one very handsome 12mo. volume of 216 pages. Cloth, $1 38. (*Just Issued.*)

FLINT (AUSTIN), M.D.,

Professor of the Principles and Practice of Medicine in Bellevue Hospital Med. College, N. Y.

A MANUAL OF PERCUSSION AND AUSCULTATION; of the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism. Second edition. In one handsome royal 12mo. volume: cloth, $1 63. (*Just Ready.*)

Prof. Flint is so well known as a medical teacher and writer that it seems superfluous to state that the subject has been treated in a thorough and systematic manner. In revising it for a second edition the author has confined himself to such additions as seem likely to render it more useful, not only to students engaged in the practical study of the subject, but also to practitioners as a handbook for ready reference, and we do not hesitate in saying that it would prove a valuable addition to every physician's library.—*Med. and Surg. Reporter*, March 18, 1880.

The little work before us has already become a standard one, and has become extensively adopted as a text-book. There is certainly none better. It contains the substance of the lessons which the author has for many years given, in connection with practical instruction in auscultation and percussion, to private classes, composed of medical students and practitioners.—*Cincinnati Med. News*, Feb. 1880.

BY THE SAME AUTHOR.

PHTHISIS: ITS MORBID ANATOMY, ETIOLOGY, SYMPTOMATIC EVENTS AND COMPLICATIONS, FATALITY AND PROGNOSIS, TREATMENT AND PHYSICAL DIAGNOSIS; in a series of Clinical Studies. By AUSTIN FLINT, M.D., Prof. of the Principles and Practice of Medicine in Bellevue Hospital Med. College, New York. In one handsome octavo volume: $3 50. (*Lately Issued.*)

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DIAGNOSIS, PATHOLOGY, AND TREATMENT OF DISEASES OF THE HEART Second revised and enlarged edition. In one octavo volume of 550 pages, with a plate, cloth, $4.

Dr. Flint chose a difficult subject for his researches, and has shown remarkable powers of observation and reflection, as well as great industry, in his treatment of it. His book must be considered the fullest and clearest practical treatise on those subjects, and should be in the hands of all practitioners and students. It is a credit to American medical literature.—*Amer. Journ. of the Med. Sciences*, July, 1860.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE PHYSICAL EXPLORATION OF THE CHEST AND THE DIAGNOSIS OF DISEASES AFFECTING THE RESPIRATORY ORGANS. Second and revised edition. In one handsome octavo volume of 595 pages, cloth, $4 50.

BROWN (LENNOX), F.R.C.S. Ed.,

Senior Surgeon to the Central London Throat and Ear Hospital, etc.

THE THROAT AND ITS DISEASES. Second American, from the Second English Edition, thoroughly revised. With one hundred Typical Illustrations in colors, and fifty wood engravings, designed and executed by the author. In one very handsome imperial octavo volume of over 300 pages. (*Preparing.*)

SEILER (CARL), M.D.,

Lecturer on Laryngoscopy at the Univ. of Penna, Chief of the Throat Dispensary at the Univ. Hospital, Phila., etc.

HANDBOOK OF DIAGNOSIS AND TREATMENT OF DISEASES OF THE THROAT AND NASAL CAVITIES. In one handsome royal 12mo. volume, of 156 pages, with 35 illustrations; cloth, $1. (*Just Ready.*)

We most heartily commend this book as showing sound judgment in practice, and perfect familiarity with the literature of the specialty it so ably epitomizes.—*Philada. Med. Times*, July 5, 1879.

A convenient little handbook, clear, concise, and accurate in its method, and admirably fulfilling its purpose of bringing the subject of which it treats within the comprehension of the general practitioner.—*N. C. Med. Jour.*, June, 1879.

WILLIAMS'S PULMONARY CONSUMPTION; its Nature, Varieties, and Treatment. With an Analysis of One Thousand Cases to exemplify its duration. In one neat octavo volume of about 250 pages; cloth, $2 50.

SLADE ON DIPHTHERIA; its Nature and Treatment, with an account of the History of its Prevalence in various Countries. Second and revised edition. In one neat royal 12mo. volume, cloth, $1 25.

WALSHE ON THE DISEASES OF THE HEART AND GREAT VESSELS. Third American Edition. In 1 vol. 8vo., 420 pp., cloth, $3 00.

CHAMBERS'S MANUAL OF DIET AND REGIMEN IN HEALTH AND SICKNESS. In one handsome octavo volume. Cloth, $2 75.

LA ROCHE ON PNEUMONIA. 1 vol. 8vo., cloth, of 500 pages. Price, $3 00.

WILSON'S STUDENT'S BOOK OF CUTANEOUS MEDICINE and DISEASES OF THE SKIN. In one very handsome royal 12mo. volume. $3 50.

FULLER ON DISEASES OF THE LUNGS AND AIR-PASSAGES. Their Pathology, Physical Diagnosis, Symptoms, and Treatment. From the second and revised English edition. In one handsome octavo volume of about 500 pages: cloth, $3 50.

SMITH ON CONSUMPTION; ITS EARLY AND REMEDIABLE STAGES. 1 vol. 8vo., pp. 254. $2 25.

BASHAM ON RENAL DISEASES: a Clinical Guide to their Diagnosis and Treatment. With Illustrations. In one 12mo. vol. of 304 pages, cloth, $2 00.

LECTURES ON THE STUDY OF FEVER. By A. HUDSON, M.D., M.R.I.A., Physician to the Meath Hospital In one vol 8vo., cloth, $2 50.

A TREATISE ON FEVER. By ROBERT D. LYONS, K.C.C. In one octavo volume of 362 pages, cloth $2 25

HILLIER'S HANDBOOK OF SKIN DISEASES, for Students and Practitioners. Second Am. Ed. In one royal 12mo. vol. of 358 pp. With illustrations. Cloth, $2 25.

BUMSTEAD (FREEMAN J.), M.D., LL.D.,

Professor of Venereal Diseases at the Col. of Phys. and Surg., New York, &c.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES.

Including the results of recent investigations upon the subject. Fourth edition, revised and largely rewritten with the co-operation of R. W. Taylor, M.D., of New York, Prof. of Dermatology in the Univ. of Vt. In one large and handsome octavo volume of 835 pages, with 138 illustrations. Cloth, $4 75; leather, $5 75; half Russia, $6 25. (*Now Ready.*)

This work, on its first appearance, immediately took the position of a standard authority on its subject wherever the language is spoken, and the success of an Italian translation shows that it is regarded with equal favor on the Continent of Europe. In repeated editions the author labored sedulously to render it more worthy of its reputation, and in the present revision no pains have been spared to perfect it as far as possible. Several years having elapsed since the publication of the third edition, much material has been accumulated during the interval by the industry of syphilologists, and new views have been enunciated. All this so far as confirmed by observation and experience, has been incorporated; many portions of the volume been rewritten, the series of illustrations has been enlarged and improved, and the whole may be regarded rather as a new work than as a new edition. It is confidently presented as fully on a level with the most advanced condition of syphilology, and as a work to which the practitioner may refer with the certainty of finding clearly and succinctly set forth whatever falls within the scope of such a treatise.

We have to congratulate our countrymen upon the truly valuable addition which they have made to American literature. The careful estimate of the value of the volume, which we have made, justifies us in declaring that this is the best treatise on venereal diseases in the English language, and, we might add, if there is a better in any other tongue we cannot name it; there are certainly no books in which the student or the general practitioner can find such an excellent *résumé* of the literature of any topic, and such practical suggestions regarding the treatment of the various complications of every venereal disease. We take pleasure in repeating that we believe this to be the best treatise on venereal disease in the English language, and we congratulate the authors upon their brilliant addition to American medical literature.—*Chicago Med. Journal and Examiner*, February, 1880.

It is, without exception, the most valuable single work on all branches of the subject of which it treats in any language. The pathology is sound, the work is, at the same time, in the highest degree practical, and the hints that he will get from it for the management of any one case, at all obscure or obstinate, will more than repay him for the outlay.—*Archives of Medicine*, April, 1880.

This now classical work on venereal disease comes to us in its fourth edition rewritten, enlarged, and materially improved in every way. Dr. Taylor, as we had every reason to expect, has performed this part of his work with unusual excellence. We feel that what has been written has done but scanty justice to the merits of this truly great treatise.—*St. Louis Courier of Medicine*, Feb. 1880

We find that we have here practically a new book—that the statement of the title page, as to the fact that it has been largely rewritten, is a sufficiently modest announcement for the important changes in the text. After a thorough examination of the present edition, we can assert confidently that the enormous labor we have described has been here most faithfully and conscientiously performed.—*Amer. Journ. Med. Sci.*, Jan 1880.

It is one of the best general treatises on venereal diseases with which we are acquainted, and is especially to be recommended as a guide to the treatment of syphilis.—*London Practitioner*, March, 1880.

GROSS (SAMUEL W.), A.M., M.D.,

Lecturer on Genito-Urinary and Venereal Diseases in the Jefferson Medical College, Phila.

A PRACTICAL TREATISE ON IMPOTENCE, STERILITY, AND ALLIED DISORDERS OF THE MALE SEXUAL ORGANS.

In one handsome octavo volume, with illustrations. (*Preparing.*)

CULLERIER (A.), *Surgeon to the Hôpital du Midi.* and BUMSTEAD (FREEMAN J.), *Professor of Venereal Diseases in the College of Physicians and Surgeons, N. Y.*

AN ATLAS OF VENEREAL DISEASES.

Translated and Edited by FREEMAN J. BUMSTEAD. In one large imperial 4to. volume of 328 pages, double-columns, with 26 plates, containing about 150 figures, beautifully colored, many of them the size of life; strongly bound in cloth, $17 00; also, in five parts, stout wrappers, at $3 per part.

Anticipating a very large sale for this work, it is offered at the very low price of THREE DOLLARS a Part, thus placing it within the reach of all who are interested in this department of practice. Gentlemen desiring early impressions of the plates would do well to order it without delay. A specimen of the plates and text sent free by mail, on receipt of 25 cents.

LEE'S LECTURES ON SYPHILIS AND SOME FORMS OF LOCAL DISEASE AFFECTING PRINCIPALLY THE ORGANS OF GENERATION. In one handsome octavo volume; cloth, $2 25.

CONDIE'S PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Sixth edition, revised and augmented. In one large octavo volume of nearly 800 closely-printed pages, cloth, $5 25; leather, $6 25.

HILL ON SYPHILIS AND LOCAL CONTAGIOUS DISORDERS. In one handsome octavo volume; cloth $3 25.

SMITH'S PRACTICAL TREATISE ON THE WASTING DISEASES OF INFANCY AND CHILDHOOD. Second American, from the second revised and enlarged English edition. In one handsome octavo volume, cloth, $2 50.

SMITH (J. LEWIS), M.D.,

Clinical Professor of Diseases of Children in the Bellevue Hospital Med. College, N.Y.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. Fifth Edition, thoroughly revised and rewritten. In one handsome octavo volume of about 800 pages, with illustrations. (*Preparing.*)

The very marked favor with which this work has been received wherever the English language is spoken, has stimulated the author, in the preparation of the Fifth Edition, to spare no pains in the endeavor to render it worthy in every respect of a continuance of professional confidence. Many portions of the volume have been rewritten, and much new matter introduced, but by an earnest effort at condensation, the size of the work will not be materially increased.

WEST (CHARLES), M.D.,

Physician to the Hospital for Sick Children, London, &c.

LECTURES ON THE DISEASES OF INFANCY AND CHILDHOOD. Fifth American from the sixth revised and enlarged English edition. In one large and handsome octavo volume of 678 pages. Cloth, $4 50; leather, $5 50. (*Lately Issued.*)

BY THE SAME AUTHOR. (*Lately Issued.*)

ON SOME DISORDERS OF THE NERVOUS SYSTEM IN CHILDHOOD; being the Lumleian Lectures delivered at the Royal College of Physicians of London, in March, 1871. In one volume small 12mo., cloth, $1 00.

BY THE SAME AUTHOR.

LECTURES ON THE DISEASES OF WOMEN. Third American, from the Third London edition. In one neat octavo volume of about 550 pages, cloth, $3 75; leather, $4 75.

SWAYNE (JOSEPH GRIFFITHS), M.D.,

Physician-Accoucheur to the British General Hospital, &c.

OBSTETRIC APHORISMS FOR THE USE OF STUDENTS COMMENCING MIDWIFERY PRACTICE. Second American, from the Fifth and Revised London Edition, with Additions by E. R. HUTCHINS, M.D. With Illustrations. In one neat 12mo. volume. Cloth, $1 25. (*Lately Issued.*)

*** See p. 3 of this Catalogue for the terms on which this work is offered as a premium to subscribers to the AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

CHURCHILL ON THE PUERPERAL FEVER AND OTHER DISEASES PECULIAR TO WOMEN. 1 vol. 8vo., pp. 450, cloth. $2 50.

DEWEES'S TREATISE ON THE DISEASES OF FEMALES. With Illustrations. Eleventh Edition, with the Author's last improvements and corrections. In one octavo volume of 536 pages, with plates, cloth. $3 00.

MEIGS ON THE NATURE, SIGNS, AND TREATMENT OF CHILDBED FEVER. 1 vol. 8vo., pp. 365, cloth. $2 00.

ASHWELL'S PRACTICAL TREATISE ON THE DISEASES PECULIAR TO WOMEN. Third American, from the Third and revised London edition. 1 vol. 8vo., pp. 628, cloth. $3 50.

HODGE (HUGH L.), M.D.,

Emeritus Professor of Obstetrics, &c., in the University of Pennsylvania.

ON DISEASES PECULIAR TO WOMEN; including Displacements of the Uterus. With original illustrations. Second edition, revised and enlarged. In one beautifully printed octavo volume of 531 pages, cloth, $4 50.

CHURCHILL (FLEETWOOD), M.D., M.R.I.A.

ON THE THEORY AND PRACTICE OF MIDWIFERY. A new American from the fourth revised and enlarged London edition. With notes and additions by D. FRANCIS CONDIE, M.D., author of a Practical Treatise on the Diseases of Children, &c. With one hundred and ninety-four illustrations. In one very handsome octavo volume of nearly 700 large pages. Cloth, $4 00; leather, $5 00.

WINCKEL (F.),

Professor and Director of the Gynæcological Clinic in the University of Rostock.

A COMPLETE TREATISE ON THE PATHOLOGY AND TREATMENT OF CHILDBED, for Students and Practitioners. Translated, with the consent of the author, from the Second German Edition, by JAMES READ CHADWICK, M.D. In one octavo volume. Cloth, $4 00. (*Lately Issued.*)

MONTGOMERY'S EXPOSITION OF THE SIGNS AND SYMPTOMS OF PREGNANCY. With two exquisite colored plates, and numerous wood-cuts. In 1 vol. 8vo., of nearly 600 pp., cloth, $3 75.

RIGBY'S SYSTEM OF MIDWIFERY. With notes and Additional Illustrations. Second American edition. One volume octavo, cloth, 422 pages, $2 50.

THOMAS (T. GAILLARD), M.D.,

Professor of Obstetrics, &c., in the College of Physicians and Surgeons, N. Y., &c

A PRACTICAL TREATISE ON THE DISEASES OF WOMEN.

Fifth edition, thoroughly revised and rewritten. In one large and handsome octavo volume of over 800 pages, with 266 illustrations. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50. (*Just Ready.*)

The author has taken advantage of the opportunity afforded by the call for a new edition of this work to render it worthy a continuance of the very remarkable favor with which it has been received. Every portion of the work has been carefully revised, very much of it has been rewritten, and additions and alterations introduced wherever the advance of science and the increased experience of the author have shown them desirable. At the same time special care has been exercised to avoid undue increase in the size of the volume. To accommodate the numerous additions a more condensed but very clear letter has been used, notwithstanding which, the number of pages has been increased by more than fifty. The series of illustrations has been extensively changed; many which seemed to be superfluous have been omitted, and a large number of new and superior drawings have been inserted. In its improved form, therefore, it is hoped that the volume will maintain the character it has acquired of a standard authority on every detail of its important subject.

An examination of the work will satisfy that it is one of great merit. It is not a mere compilation from other works, but is the fruit of the ripe thought, sound judgment, and critical observations of a learned, scientific man. It is a treasury of knowledge of the department of medicine to which it is devoted. In its present revised state it certainly holds a foremost position as a gynæcological work, and will continue to be regarded as a standard authority.—*Cincinnati Med. News*, Dec. 1880.

This work needs no introduction to any of the civilized nations of the world. The edition before us adds to the strength of former volumes. With the wisdom of a master teacher he here gives the results that, in his judgment, are most trustworthy at the present time. In its own place it has no rival, because the author is the best teacher on this subject to the masses of the profession. As hitherto this work will be the text-book on diseases of women. We only wish that in other branches of medicine as capable teachers could be found to write our text-books.—*Detroit Lancet*, Jan. 1881.

Since its first appearance, twelve years ago, until the present day, it has held a position of high regard, and is generally conceded to be one of the most practical and trustworthy volumes yet presented to the physician and student in the department of gynæcology. The work embodies not only its author's large experience, but reflects his careful study among other authorities in this branch, both at home and abroad. Dr. Thomas is an able and conscientious teacher. His writings convey his meaning in the same practical and instructive manner. The last edition of this work is fresh from his pen, with decided changes and improvements over former editions. His book presents generally accepted facts, and as a guide to the student is more useful and reliable than any work in the language on diseases of women. This last edition will add new laurels to those already won.—*Md. Med. Journ.*, Nov. 15, 1880.

It has been enlarged and carefully revised. The author has brought it fully abreast with the times, and as the wave of gynæcological progression has been widespread and rapid during the twelve years that have elapsed since the issue of the first edition, one can conceive of the great improvement this edition must be upon the earlier. It is a condensed encyclopædia of gynæcological medicine. The style of arrangement, the masterly manner in which each subject is treated, and the honest convictions derived from probably the largest clinical experience in that specialty of any in this country, all serve to commend it in the highest terms to the practitioner.—*Nashville Journ. of Med. and Surg.*, Jan. 1881.

BARNES (ROBERT), M.D., F.R.C.P.,

Obstetric Physician to St. Thomas's Hospital, &c.

A CLINICAL EXPOSITION OF THE MEDICAL AND SURGICAL DISEASES OF WOMEN.

Second American, from the Second Enlarged and Revised English Edition. In one handsome octavo volume, of 784 pages, with 181 illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Issued.*)

Dr Barnes stands at the head of his profession in the old country, and it requires but scant scrutiny of his book to show that it has been sketched by a master. It is plain, practical common sense; shows very deep research without being pedantic; is eminently calculated to inspire enthusiasm without inculcating rashness; points out the dangers to be avoided as well as the success to be achieved in the various operations connected with this branch of medicine; and will do much to smooth the rugged path of the young gynæcologist and relieve the perplexity of the man of mature years.—*Canadian Journ. of Med. Science*, Nov. 1878.

We pity the doctor who, having any considerable practice in diseases of women, has no copy of "Barnes" for daily consultation and instruction. It is at once a book of great learning, research, and individual experience, and at the same time eminently practical. That it has been appreciated by the profession, both in Great Britain and in this country, is shown by the second edition following so soon upon the first.—*Am. Practitioner*, Nov. 1878.

Dr. Barnes's work is one of a practical character, largely illustrated from cases in his own experience, but by no means confined to such, as will be learned from the fact that he quotes from no less than 628 medical authors in numerous countries. Coming from such an author, it is not necessary to say that the work is a valuable one, and should be largely consulted by the profession.—*Am. Supp. Obstetrical Journ. Gt. Britain and Ireland*, Oct. 1878.

No other gynæcological work holds a higher position, having become an authority everywhere in diseases of women. The work has been brought fully abreast of present knowledge. Every practitioner of medicine should have it upon the shelves of his library, and the student will find it a superior text-book.—*Cincinnati Med. News*, Oct. 1878.

This second revised edition, of course, deserves all the commendation given to its predecessor, with the additional one that it appears to include all or nearly all the additions to our knowledge of its subject that have been made since the appearance of the first edition. The American references are, for an English work, especially full and appreciative, and we can cordially recommend the volume to American readers.—*Journ. of Nervous and Mental Disease*, Oct. 1878.

This second edition of Dr. Barnes's great work comes to us containing many additions and improvements which bring it up to date in every feature. The excellences of the work are too well known to require enumeration, and we hazard the prophecy that they will for many years maintain its high position as a standard text-book and guide-book for students and practitioners.—*N. O. Med. Journ.*, Oct. 1878.

EMMET (*THOMAS ADDIS*), *M.D.*,

Surgeon to the Woman's Hospital, New York, etc.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY, for the use of Students and Practitioners of Medicine. Second Edition. Thoroughly Revised. In one large and very handsome octavo volume of 875 pages, with 133 illustrations. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready.*)

PREFACE TO THE SECOND EDITION.

The unusually rapid exhaustion of a large edition of this work, while flattering to the author as an evidence that his labors have proved acceptable, has in a great measure heightened his sense of responsibility. He has therefore endeavored to take full advantage of the opportunity afforded to him for its revision. Every page has received his earnest scrutiny; the criticisms of his reviewers have been carefully weighed; and while no marked increase has been made in the size of the volume, several portions have been rewritten, and much new matter has been added. In this minute and thorough revision, the labor involved has been much greater than is perhaps apparent in the results, but it has been cheerfully expended in the hope of rendering the work more worthy of the favor which has been accorded to it by the profession.

In no country of the world has gynæcology received more attention than in America. It is, then, with a feeling of pleasure that we welcome a work on diseases of women from so eminent a gynæcologist as Dr. Emmet, and the work is essentially clinical, and leaves a strong impress of the author's individuality. To criticise, with the care it merits, the book throughout, would demand far more space than is at our command. In parting, we can say that the work teems with original ideas, fresh and valuable methods of practice, and is written in a clear and elegant style, worthy of the literary reputation of the country of Longfellow and Oliver Wendell Holmes.—*Brit. Med. Journ.* Feb. 21, 1880.

No gynæcological treatise has appeared which contains an equal amount of original and useful matter; nor does the medical and surgical history of America include a book more novel and useful. The tabular and statistical information which it contains is marvellous, both in quantity and accuracy, and cannot be otherwise than invaluable to future investigators. It is a work which demands not careless reading but profound study. Its value as a contribution to gynæcology is, perhaps, greater than that of all previous literature on the subject combined.—*Chicago Med. Gaz.*, April 5, 1880

The wide reputation of the author makes its publication an event in the gynæcological world; and a glance through its pages shows that it is a work to be studied with care. . . . It must always be a work to be carefully studied and frequently consulted by those who practise this branch of our profession.—*Lond. Med. Times and Gaz.*, Jan. 10, 1880.

The character of the work is too well known to require extended notice—suffice it to say that no recent work upon any subject has attained such great popularity so rapidly. As a work of general reference upon the subject of Diseases of Women it is invaluable. As a record of the largest clinical experience and observation it has no equal. No physician who pretends to keep up with the advances of this department of medicine can afford to be without it.—*Nashville Journ. of Medicine and Surgery*, May, 1880.

DUNCAN (*J. MATTHEWS*), *M.D., LL.D., F.R.S.E., etc.*

CLINICAL LECTURES ON THE DISEASES OF WOMEN, Delivered in Saint Bartholomew's Hospital. In one very neat octavo volume of 178 pages. Cloth, $1 50. (*Just Ready.*)

They are in every way worthy of their author; indeed, we look upon them as among the most valuable of his contributions. They are all upon matters of great interest to the general practitioner. Some of them deal with subjects that are not, as a rule, adequately handled in the text-books; others of them, while bearing upon topics that are usually treated of at length in such works, yet bear such a stamp of individuality that, if widely read, as they certainly deserve to be, they cannot fail to exert a wholesome restraint upon the undue eagerness with which many young physicians seem bent upon following the wild teachings which so infest the gynæcology of the present day.—*N. Y. Med. Journ.*, March, 1880.

The author is a remarkably clear lecturer, and his discussion of symptoms and treatment is full and suggestive. It will be a work which will not fail to be read with benefit by practitioners as well as by students.—*Phila. Med. and Surg. Reporter*, Feb. 7, 1880.

We have read this book with a great deal of pleasure. It is full of good things. The hints on pathology and treatment scattered through the book are sound, trustworthy, and of great value. A healthy scepticism, a large experience, and a clear judgment are everywhere manifest. Instead of bristling with advice of doubtful value and unsound character, the book is in every respect a safe guide.—*The London Lancet*, Jan. 21, 1880.

RAMSBOTHAM (*FRANCIS H.*), *M.D.*

THE PRINCIPLES AND PRACTICE OF OBSTETRIC MEDICINE AND SURGERY, in reference to the Process of Parturition. A new and enlarged edition, thoroughly revised by the author. With additions by W. V. KEATING, M. D., Professor of Obstetrics, &c., in the Jefferson Medical College, Philadelphia. In one large and handsome imperial octavo volume of 650 pages, strongly bound in leather, with raised bands; with sixty-four beautiful plates, and numerous wood-cuts in the text, containing in all nearly 200 large and beautiful figures. $7 00

PARRY (*JOHN S.*), *M.D.*,

Obstetrician to the Philadelphia Hospital, Vice-Pres't of the Obstet. Society of Philadelphia.

EXTRA-UTERINE PREGNANCY: ITS CLINICAL HISTORY, DIAGNOSIS, PROGNOSIS, AND TREATMENT. In one handsome octavo volume. Cloth, $2 50. (*Lately Issued.*)

TANNER (*THOMAS H.*), *M.D.*

ON THE SIGNS AND DISEASES OF PREGNANCY. First American from the Second and Enlarged English Edition. With four colored plates and illustrations on wood. In one handsome octavo volume of about 500 pages, cloth, $4 25.

LEISHMAN (*WILLIAM*), *M.D.*,

Regius Professor of Midwifery in the University of Glasgow, &c.

A SYSTEM OF MIDWIFERY, INCLUDING THE DISEASES OF PREGNANCY AND THE PUERPERAL STATE.

Third American edition, revised by the Author, with additions by JOHN S. PARRY, M.D., Obstetrician to the Philadelphia Hospital, &c. In one large and very handsome octavo volume, of 733 pages, with over two hundred illustrations. Cloth, $4 50; leather, $5 50; half Russia, $6. (*Just Ready.*)

Few works on this subject have met with as great a demand as this one appears to have. To judge by the frequency with which its author's views are quoted, and its statements referred to in obstetrical literature, one would judge that there are few physicians devoting much attention to obstetrics who are without it. The author is evidently a man of ripe experience and conservative views, and in no branch of medicine are these more valuable than in this.—*New Remedies*, Jan. 1880.

We gladly welcome the new edition of this excellent text-book of midwifery. The former editions have been most favorably received by the profession on both sides of the Atlantic In the preparation of the present edition the author has made such alterations as the progress of obstetrical science seems to require, and we cannot but admire the ability with which the task has been performed. We consider it an admirable text-book for students during their attendance upon lectures, and have great pleasure in recommending it. As an exponent of the midwifery of the present day it has no superior in the English language.—*Canada Lancet*, Jan. 1880.

To the American student the work before us must prove admirably adapted, complete in all its parts, essentially modern in its teachings and with demonstrations noted for clearness and precision, it will gain in favor and be recognized as a work of standard merit. The work cannot fail to be popular, and is cordially recommended.—*N. O. Med. and Surg. Journ.*, March, 1880.

Leishman's is certainly one of the best systematic works on midwifery. It is very complete in all the parts essential for such a treatise To practitioners and students it is to be strongly recommended as a safe and reliable guide to the modern practice of midwifery.—*Canada Med. and Surg. Journal*. March, 1880.

This is a book of well-established reputation, both in England and America. The present edition has been revised with care by the distinguished author, and supplied with such additions and emendations as the rapid advances in obstetrical science demand. *Pacific Med. and Surg. Journ.*, May, 1880.

The book is greatly improved, and as such will be welcomed by those who are trying to keep posted in the rapid advances which are being made in the study of obstetrics.—*Boston Med. and Surg. Journ.*, Nov 27, 1879.

This work is a thoroughly good one, and is well adapted to the requirements of the practical obstetrician. It is something more than a compend designed for the medical student: it is a book to be studied by the practitioner, and it will seldom disappoint him. It is of convenient size, clearly written, and eminently practical. As such, we heartily commend it to our readers —*St. Louis Clin. Record*, Jan. 1880.

We are glad to call the attention of our readers to this new edition of Dr. Leishman's well-known work, which has already established itself in general favor both in this country and in America. In noticing this third edition we need only direct attention to the differences between it and its predecessor. Although carefully revised throughout, with not a few additions in various places, the net enlargement amounts only to a few pages.—*Glasgow Med. Journ.*, Jan. 1880.

Leishman's is certainly one of the best systematic works on midwifery. It is very complete in all the parts essential for such a treatise. To practitioners and students it is to be strongly recommended as a safe and reliable guide to the modern practice of midwifery.—*Canada Med. and Surg. Journal*, March, 1880.

It has been well and carefully written. The view of the author are broad and liberal, and indicate a well balanced judgment and matured mind. We observe no spirit of dogmatism, but the earnest teaching of the thoughtful observer and lover of true science. Take the volume as a whole, and it has few equals.—*Md. Med. Journ.*, Feb. 1880.

Dr Leishman is too well known to the profession, not only that but to the student who is about to enter the profession, to need any introduction. Of his work, we need but say that it is a standard, sound and practical.—*St Louis Courier of Med.*, Jan. 1880.

PARVIN (*THEOPHILUS*), *M.D.*,

Prof. of Obstetrics and of the Med. and Surg. Diseases of Women in the Med. Coll. of Indiana.

A TREATISE ON MIDWIFERY.

In one very handsome octavo volume of about 550 pages, with numerous illustrations. (*Preparing.*)

HODGE (*HUGH L.*), *M.D.*,

Emeritus Professor of Midwifery, &c., in the University of Pennsylvania, &c.

THE PRINCIPLES AND PRACTICE OF OBSTETRICS.

Illustrated with large lithographic plates containing one hundred and fifty-nine figures from original photographs, and with numerous wood-cuts. In one large and beautifully printed quarto volume of 550 double-columned pages, strongly bound in cloth, $14.

The work of Dr. Hodge is something more than a simple presentation of his particular views in the department of Obstetrics; it is something more than an ordinary treatise on midwifery; it is, in fact, a cyclopædia of midwifery. He has aimed to embody in a single volume the whole science and art of Obstetrics. An elaborate text is combined with accurate and varied pictorial illustrations, so that no fact or principle is left unstated or unexplained. —*Am. Med. Times*, Sept. 8, 1864.

*** Specimens of the plates and letter-press will be forwarded to any address, free by mail, on receipt of six cents in postage stamps.

CHADWICK (*JAMES R.*), *A.M.*, *M.D.*

A MANUAL OF THE DISEASES PECULIAR TO WOMEN.

In one neat volume, royal 12mo., with illustrations. (*Preparing.*)

PLAYFAIR (W. S.). M.D., F.R.C.P.,

Professor of Obstetric Medicine in King's College, etc. etc.

A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY.

Third American edition, revised by the author. Edited, with additions, by ROBERT P. HARRIS, M D. In one handsome octavo volume of about 700 pages, with nearly 200 illustrations. Cloth, $4; leather, $5; half Russia, $5 50. (*Just Ready.*)

EXTRACT FROM THE AUTHOR'S PREFACE.

The second American edition of my work on Midwifery being exhausted before the corresponding English edition, I cannot better show my appreciation of the kind reception my book has received in the United States than by acceding to the publisher's request that I should myself undertake the issue of a third edition. As little more than a year has elapsed since the second edition was issued, there are naturally not many changes to make, but I have, nevertheless, subjected the entire work to careful revision, and introduced into it a notice of most of the more important recent additions to obstetric science. To the operation of gastrotrytotomy—formerly described along with the Cæsarean section—I have now devoted a separate chapter. The editor of the Second American edition, Dr. Harris, enriched it with many valuable notes, of which, it will be observed, I have freely availed myself.

The medical profession has now the opportunity of adding to their stock of standard medical works one of the best volumes on midwifery ever published. The subject is taken up with a master hand. The part devoted to labor in all its various presentations, the management and results, is admirably arranged, and the views entertained will be found essentially modern, and the opinions expressed trustworthy. The work abounds with plates, illustrating various obstetrical positions; they are admirably wrought, and afford great assistance to the student.—*N. O. Med. and Surg. Journ.*, March, 1880.

If inquired of by a medical student what work on obstetrics we should recommend for him, as *par excellence*, we would undoubtedly advise him to choose Playfair's. It is of convenient size, but what is of chief importance, its treatment of the various subjects is concise and plain. While the discussions and descriptions are sufficiently elaborate to render a very intelligent idea of them, yet all details not necessary for a full understanding of the subject are omitted.—*Cincinnati Med. News*, Jan. 1880.

The rapidity with which one edition of this work follows another is proof alike of its excellence and of the estimate that the profession has formed of it. It is indeed so well known and so highly valued that nothing need be said of it as a whole. All things considered, we regard this treatise as the very best on Midwifery in the English language.—*N. Y. Medical Journal*, May, 1880

It certainly is an admirable exposition of the Science and Practice of Midwifery. Of course the additions made by the American editor, Dr. R. P. Harris, who never utters an idle word, and whose studious researches in some special departments of obstetrics are so well known to the profession, are of great value.—*The American Practitioner*, April, 1880

BARNES (FANCOURT), M.D.,

Physician to the General Lying-in Hospital, London.

A MANUAL OF MIDWIFERY FOR MIDWIVES AND MEDICAL STUDENTS.

With 50 illustrations. In one neat royal 12mo. volume of 200 pages; cloth, $1 25. (*Now Ready.*)

The book is written in plain, and as far as possible in untechnical language. Any intelligent midwife or medical student can easily comprehend the directions. It will undoubtedly fill a want, and will be popular with those for whom it has been prepared. The examining questions at the back will be found very useful.—*Cincinnati Med. News*, Aug. 1879.

STIMSON (LEWIS A.), A.M., M.D.,

Surgeon to the Presbyterian Hospital.

A MANUAL OF OPERATIVE SURGERY.

In one very handsome royal 12mo. volume of about 500 pages, with 332 illustrations; cloth, $2 50. (*Just Issued.*)

The work before us is a well printed, profusely illustrated manual of over four hundred and seventy pages. The novice, by a perusal of the work, will gain a good idea of the general domain of operative surgery, while the practical surgeon has presented to him within a very concise and intelligible form the latest and most approved selections of operative procedure. The precision and conciseness with which the different operations are described enable the author to compress an immense amount of practical information in a very small compass.—*N. Y. Medical Record*, Aug. 3, 1878.

This volume is devoted entirely to operative surgery, and is intended to familiarize the student with the details of operations and the different modes of performing them. The work is handsomely illustrated, and the descriptions are clear and well drawn. It is a clever and useful volume; every student should possess one. The preparation of this work does away with the necessity of pondering over larger works on surgery for descriptions of operations, as it presents in a nut-shell just what is wanted by the surgeon without an elaborate search to find it.—*Md. Med Journal*, Aug. 1878.

The author's conciseness and the repleteness of the work with valuable illustrations entitle it to be classed with the text-books for students of operative surgery, and as one of reference to the practitioner. —*Cincinnati Lancet and Clinic*, July 27, 1878.

LEY'S OPERATIVE SURGERY. In 1 vol. 8vo. cl., of 650 pages; with about 100 wood-cuts. $3 25.

OPER'S LECTURES ON THE PRINCIPLES AND PRACTICE OF SURGERY. In 1 vol. 8vo. cl'h, 750 p. $2.

SON'S INSTITUTES AND PRACTICE OF SURGERY. Eighth edit'n, improved and altered. With thirty-four plates. In two handsome octavo volumes, about 1000 pp., leather, raised bands. $6 50.

PRINCIPLES AND PRACTICE OF SURGERY. By WILLIAM PIRRIE, F.R.S.E., Professor of Surgery in the University of Aberdeen. Edited by JOHN NEILL, M.D., Professor of Surgery in the Penna. Medical College, Surg'n to the Pennsylvania Hospital, &c. In one very handsome octavo vol. of 780 pages, with 316 illustrations, cloth, $3 75.

MILLER'S PRINCIPLES OF SURGERY. Fourth American, from the Third Edinburgh Edition. In one large 8vo. vol. of 700 pages, with 340 illustrations, cloth, $3 75.

MILLER'S PRACTICE OF SURGERY. Fourth American, from the last Edinburgh Edition Revised by the American editor. In one large 8vo. vol. of nearly 700 pages, with 364 illustrations: cloth, $3 75.

GROSS (*SAMUEL D.*), *M.D.*,

Professor of Surgery in the Jefferson Medical College of Philadelphia.

SYSTEM OF SURGERY: Pathological, Diagnostic, Therapeutic, and Operative.

Illustrated by upwards of Fourteen Hundred Engravings. Fifth edition, carefully revised and improved. In two large and beautifully printed imperial octavo volumes of about 2300 pp., strongly bound in leather, with raised bands, $15; half Russia, raised bands, $16.

The continued favor, shown by the exhaustion of successive large editions of this great work, proves that it has successfully supplied a want felt by American practitioners and students. In the present revision no pains have been spared by the author to bring it in every respect fully up to the day. To effect this a large part of the work has been rewritten, and the whole enlarged by nearly one-fourth, notwithstanding which the price has been kept at its former very moderate rate. By the use of a close, though very legible type, an unusually large amount of matter is condensed in its pages, the two volumes containing as much as four or five ordinary octavos. This, combined with the most careful mechanical execution, and its very durable binding, renders it one of the cheapest works accessible to the profession. Every subject properly belonging to the domain of surgery is treated in detail, so that the student who possesses this work may be said to have in it a surgical library.

We have seldom read a work with the practical value of which we have been more impressed. Every chapter is so concisely put together, that the busy practitioner, when in difficulty, can at once find the information he requires. His work is cosmopolitan, the surgery of the world being fully represented in it. The work, in fact, is so historically unprejudiced, and so eminently practical, that it is almost a false compliment to say that we believe it to be destined to occupy a foremost place as a work of reference, while a system of surgery like the present system of surgery is the practice of surgeons. The printing and binding of the work is unexceptionable; indeed, it contrasts, in the latter respect, remarkably with English medical and surgical cloth-bound publications, which are generally so wretchedly stitched as to require re-binding before they are any time in use.—*Dub. Journ. of Med. Sci.*, March, 1874.

Dr. Gross's Surgery, a great work, has become still greater, both in size and merit, in its most recent form. The difference in actual number of pages is not more than 130, but the size of the page having been increased to what we believe is technically termed "elephant," there has been room for considerable additions, which, together with the alterations, are improvements.—*Lond. Lancet*, Nov. 16, 1872.

It combines, as perfectly as possible, the qualities of a text-book and work of reference. We think this last edition of Gross's "Surgery," will confirm his title of "*Primus inter Pares.*" It is learned, scholar-like, methodical, precise, and exhaustive. We scarcely think any living man could write so complete and faultless a treatise, or comprehend more solid, instructive matter in the given number of pages. The labor must have been immense, and the work gives evidence of great powers of mind, and the highest order of intellectual discipline and methodical disposition and arrangement of acquired knowledge and personal experience.—*N.Y. Med. Journ.*, Feb. 1873.

As a whole, we regard the work as the representative "System of Surgery" in the English language.—*St. Louis Medical and Surg. Journ.*, Oct. 1872.

The two magnificent volumes before us afford a very complete view of the surgical knowledge of the day. Some years ago we had the pleasure of presenting the first edition of Gross's Surgery to the profession as a work of unrivalled excellence; and now we have the result of years of experience, labor, and study, all condensed upon the great work before us. And to students or practitioners desirous of enriching their library with a treasure of reference, we can simply commend the purchase of these two volumes of immense research.—*Cincinnati Lancet and Observer*, Sept. 1872.

A complete system of surgery—not a mere text-book of operations, but a scientific account of surgical theory and practice in all its departments.—*Brit. and For. Med. Chir. Rev.*, Jan. 1873.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON THE DISEASES, INJURIES, and Malformations of the Urinary Bladder, the Prostate Gland, and the Urethra.

Third Edition, thoroughly Revised and Condensed, by SAMUEL W GROSS, M.D., Surgeon to the Philadelphia Hospital. In one handsome octavo volume of 574 pages, with 170 illustrations: cloth, $4 50. (*Just Issued.*)

For reference and general information, the physician or surgeon can find no work that meets their necessities more thoroughly than this, a revised edition of an excellent treatise, and no medical library should be without it. Replete with handsome illustrations and good ideas, it has the unusual advantage of being easily comprehended, by the reasonable and practical manner in which the various subjects are systematized and arranged. We heartily recommend it to the profession as a valuable addition to the important literature of diseases of the urinary organs.—*Atlanta Med. Journ.*, Oct. 1876.

It is with pleasure we now again take up this old work in a decidedly new dress. Indeed, it must be regarded as a new book in very many of its parts. The chapters on "Diseases of the Bladder," "Prostate Body," and "Lithotomy," are splendid specimens of descriptive writing; while the chapter on "Stricture" is one of the most concise and clear that we have ever read.—*New York Med. Journ.*, Nov. 1876.

BY THE SAME AUTHOR.

A PRACTICAL TREATISE ON FOREIGN BODIES IN THE AIR-PASSAGES.

In 1 vol. 8vo., with illustrations, pp. 468, cloth, $2 75.

DRUITT (*ROBERT*), *M.R.C.S., &c.*

THE PRINCIPLES AND PRACTICE OF MODERN SURGERY.

A new and revised American, from the eighth enlarged and improved London edition. Illustrated with four hundred and thirty-two wood engravings. In one very handsome octavo volume, of nearly 700 large and closely printed pages, cloth, $4 00; leather, $5 00.

All that the surgical student or practitioner could desire.—*Dublin Quarterly Journal.*

It is a most admirable book. We do not know when we have examined one with more pleasure.—*Boston Med. and Surg. Journal.*

In Mr. Druitt's book, though containing only some seven hundred pages, both the principles and the practice of surgery are treated, and so clearly and perspicuously, as to elucidate every important topic. We have examined the book most thoroughly, and can say that this success is well merited. His book, moreover, possesses the inestimable advantages of having the subjects perfectly well arranged and classified and of being written in a style at once clear and succinct.—*Am. Journal of Med. Sciences.*

HAMILTON (FRANK H.) M.D., LL.D.,

Surgeon to the Bellevue Hospital, New York.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS

Sixth edition, thoroughly revised, and much improved. In one very handsome octavo volume of over 900 pages, with 352 illustrations. Cloth, $5 50; leather, $6.50; half Russia, raised bands, $7 00.

The demand which has so speedily exhausted five large editions of this work, shows that the author has succeeded in supplying a want, felt by the profession at large, of an exhaustive treatise on a frequent and troublesome class of accidents. The unanimous voice of the profession abroad, as well as at home, has pronounced it the most complete work to which the surgeon can refer for information respecting the details of the subject. In the preparation of this new edition, the author has added a chapter on General Prognosis: that on Fractures of the Patella has been entirely rewritten, in order that the results of a recent exhaustive study of this subject might be given, and, in fact, the entire matter of the book has undergone most thorough revision. A number of illustrations have been omitted to make place for new ones, and a few have been inserted from the German edition, published at Göttingen in 1877.

So many kind expressions of welcome have been showered upon each successive edition of this valuable treatise, that scarcely any thing remains for us to do but to exchange the customary cordial greeting. It is the only complete work on the subject of Fractures in the English language We congratulate the accomplished author on the deserved success of his work, and hope that he may live to have many succeeding editions pass under his skilled supervision.—*Phila. Coll. and Clin. Record*, Nov 15, 1880.

Dr Hamilton has devoted great labor, to the study of these subjects. His large experience, extended research, and patient investigation have made him one of the highest authorities among living writers in this branch of surgery. This work is systematic and practical in its arrangement, and presents its subject matter clearly and forcibly to the reader or student.—*Maryland Medical Journal*, Nov. 15, 1880.

The only complete work on its subject in the English tongue, and, indeed, may now be said to be the only work of its kind in any tongue. It would require an exceedingly critical examination to detect in it any particulars in which it might be improved. The work is a monument to American surgery, and will long serve to keep green the memory of its venerable author.—*Michigan Med. News*, Nov. 10, 188 .

Universal verdict has pronounced it, humanly speaking, a perfect treatise upon this subject. As it is the only complete and illustrated work in any language treating of fractures and dislocations, it is safe to affirm that every wide-awake surgeon and general practitioner will regard it as indispensable to the safe and pleasant conduct of their professional work —*Detroit Lancet*, Nov. 18, 1880.

The book is known to be the only complete treatise in the English language, or in any language, and needs no recommendation. If there should still be a surgeon who does not have the book in his library, we advise him to get it immediately.—*Buffalo Med. and Surg. Journ.*, Dec. 1880

This is the sixth edition of the only work extant devoted exclusively to fractures and dislocations. That no ambitious surgeon has aspired to enter this field as a rival to Prof. Hamilton is ample testimony to the thoroughness and completeness with which he has done his work.—*Ohio Med. Recorder*, Dec 1880.

ASHHURST (JOHN, Jr.), M.D.,

Prof. of Clinical Surgery, Univ of Pa., Surgeon to the Episcopal Hospital, Philadelphia.

THE PRINCIPLES AND PRACTICE OF SURGERY.

Second edition, enlarged and revised. In one very large and handsome octavo volume of over 1000 pages, with 542 illustrations. Cloth, $6; leather, $7; half Russia, $7.50. (*Just Ready.*)

Conscientiousness and thoroughness are two very marked traits of character in the author of this book. Out of these traits largely has grown the success of his mental fruit in the past, and the present offer seems in no wise an exception to what has gone before. The general arrangement of the volume is the same as in the first edition, but every part has been carefully revised, and much new matter added.—*Phila. Med. Times*, Feb. 1, 1879.

We have previously spoken of Dr. Ashhurst's work in terms of praise. We wish to reiterate those terms here, and to add that no more satisfactory representation of modern surgery has yet fallen from the press. In point of judicial fairness, of power of condensation, of accuracy and conciseness of expression and thoroughly good English, Prof. Ashhurst has no superior among the surgical writers in America.—*Am. Practitioner*, Jan. 1879.

The attempt to embrace in a volume of 1000 pages the whole field of surgery, general and special, would be a hopeless task unless through the most tireless industry in collating and arranging, and the wisest judgment in condensing and excluding. These facilities have been abundantly employed by the author, and he has given us a most excellent treatise, brought up by the revision for the second edition to the latest date. Of course this book is not designed for specialists, but as a course of general surgical knowledge and for general practitioners, and as a text-book for students it is not surpassed by any that has yet appeared, whether of home or foreign authorship.—*N. Carolina Med. Journal*, Jan. 1879.

The favorable reception of the first edition is a guarantee of the popularity of this edition, which is fresh from the editor's hands with many enlargements and improvements. The author of this work is deservedly popular as an editor and writer, and his contributions to the literature of surgery have gained for him wide reputation. The volume now offered the profession will add new laurels to those already won by previous contributions. We can only add that the work is well arranged, filled with practical matter, and contains in brief and clear language all that is necessary to be learned by the student of surgery whilst in attendance upon lectures, or the general practitioner in his daily routine practice.—*Md. Med. Journal*, Jan. 1879.

The fact that this work has reached a second edition so very soon after the publication of the first one, speaks more highly of its merits than anything we might say in the way of commendation. It seems to have immediately gained the favor of students and physicians.—*Cincin. Med. News*, Jan. '79.

ALLINGHAM ON THE DISEASES, INJURIES, AND MALFORMATIONS OF THE RECTUM AND ANUS: with remarks on Habitual Constipation. Second American, from the fourth and enlarged London Edition. With illustrations. In one 8vo. vol. of 287 pages, cloth, $3 25.

SARGENT ON BANDAGING AND OTHER OPERATIONS OF MINOR SURGERY. New edition, with an additional chapter on Military Surgery. One 12mo. vol. of 383 pages with 184 wood-cuts Cloth, $1 75.

BRYANT (*THOMAS*), *F.R.C.S.*,

Surgeon to Guy's Hospital.

THE PRACTICE OF SURGERY. Third American, from the Second and Revised English Edition.

Thoroughly revised and much improved, by John B. Roberts, M.D. In one large and very handsome imperial octavo volume of over 1000 pages, with 672 illustrations. Cloth, $6 50; leather, $7 50; very handsome half Russia, raised bands, $8 00. (*Just Ready.*)

Mr. Bryant's work has long been a favorite one with surgeons. As its name indicates, it is of a thoroughly practical character. It is distinctly individual in that it gives the results of the author's large and varied experience as an operator and clinical teacher, and is on that account prized deservedly high as an original work. The style is necessarily condensed, the descriptions of surgical diseases brief and to the point. The illustrations are well chosen, and the typical cases of the author's experience are full of interest, and are of more than ordinary value to the working surgeon.—*N. Y. Medical Record*, March 5, 1881.

It is a work especially adapted to the wants of students and practitioners. While not prolix, it affords instruction in sufficient detail for a full understanding of surgical principles and the treatment of surgical diseases. It embraces in its scope all the diseases that are recognized as belonging to surgery, and all traumatic injuries. In discussing these it has seemed to be the aim of the author rather to present the student with practical information, and that alone, than to burden his memory with the views of different writers, however distinguished they might have been. In this edition the whole work has been carefully revised, much of it has been rewritten, important additions have been made to almost every chapter.—*Cincinnati Med. News*, Jan. 1881.

The English edition, from which this is printed, has been carefully revised and rewritten; almost every chapter has received additions, and nearly one hundred new cuts introduced. The labors of the American editor, Dr. John B. Roberts, have very much increased the value of the book. He has introduced many new illustrations and much new material not found in the English edition. He has written too with great conciseness, which is a rare virtue in an American editor of an English work. If one could procure or wished only one surgery, this volume would certainly be selected. If he desired two, Erichsen's Surgery would be added, and if he wished a third, Gross's Surgery would justly be the work selected. As the great work of Gross is amply sufficient for the wants of any surgeon, the priority given to Erichsen, and above all others, to this work of Bryant, is no labored eulogy of the last volume, but a simple and just statement of its demonstrable and pre-eminent merits.—*Am. Med. Bi-Weekly*, Feb. 26, 1881.

ERICHSEN (*JOHN E.*),

Professor of Surgery in University College, London, etc.

THE SCIENCE AND ART OF SURGERY; being a Treatise on Surgical Injuries, Diseases, and Operations.

Carefully revised by the author from the Seventh and enlarged English Edition. Illustrated by eight hundred and sixty-two engravings on wood. In two large and beautiful octavo volumes of nearly 2000 pages: cloth, $8 50; leather, $10 50; half Russia, $11 50. (*Now Ready.*)

Of the many treatises on Surgery which it has been our task to study, or our pleasure to read, there is none which in all points has satisfied us so well as the classic treatise of Erichsen. His polished, clear style, his freedom from prejudice and hobbies, his unsurpassed grasp of his subject, and vast clinical experience, qualify him admirably to write a model text-book. When we wish, at the least cost of time, to learn the most of a topic in surgery, we turn, by preference, to his work. It is a pleasure, therefore, to see that the appreciation of it is general, and has led to the appearance of another edition.—*Med. and Surg. Reporter*, Feb. 2, 1878.

Notwithstanding the increase in size, we observe that much old matter has been omitted. The entire work has been thoroughly written up, and not merely amended by a few extra chapters. A great improvement has been made in the illustrations. One hundred and fifty new ones have been added, and many of the old ones have been redrawn. The author highly appreciates the favor with which his work has been received by American surgeons, and has endeavored to render his latest edition more than ever worthy of their approval. That he has succeeded admirably, must, we think, be the general opinion. We heartily recommend the book to both student and practitioner.—*N. Y. Med. Journal*, Feb. 1878.

The seventh edition is before the world as the last word of surgical science. There may be monographs which excel it upon certain points, but as a conspectus upon surgical principles and practice it is unrivalled. It will well reward practitioners to read it, for it has been a peculiar province of Mr. Erichsen to demonstrate the absolute interdependence of medical and surgical science. We need scarcely add, in conclusion, that we heartily commend the work to students that they may be grounded in a sound faith, and to practitioners as an invaluable guide at the bedside.—*Am. Practitioner*, April, 1878.

For the past twenty years Erichsen's Surgery has maintained its place as the leading text-book, not only in this country, but in Great Britain. That it is able to hold its ground, is abundantly proven by the thoroughness with which the present edition has been revised, and by the large amount of valuable material that has been added. Aside from this, one hundred and fifty new illustrations have been inserted, including quite a number of microscopical appearances of pathological processes. So marked is this change for the better, that the work almost appears as an entirely new one.—*Med. Record*, Feb. 23, 1878.

HOLMES (*TIMOTHY*), *M.D.*,

Surgeon to St. George's Hospital, London.

SURGERY, ITS PRINCIPLES AND PRACTICE.

In one handsome octavo volume of nearly 1000 pages, with 411 illustrations. Cloth, $6; leather, $7; half Russia, $7 50. (*Just Issued.*)

This is a work which has been looked for on both sides of the Atlantic with much interest. Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and perhaps the most brilliant writer upon surgical subjects in England. It is a book for students—and an admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its proper limits has not impaired its force and distinctness.—*N. Y. Med. Record*, April 14, 1876.

It will be found a most excellent epitome of surgery by the general practitioner who has not the time to give attention to more minute and extended works and to the medical student. In fact, we know of no one we can more cordially recommend. The author has succeeded well in giving a plain and practical account of each surgical injury and disease, and of the treatment which is most commonly advisable. It will no doubt become a popular work in the profession, and especially as a text-book.—*Cincinnati Med. News*, April, 1876.

WELLS (*J. SOELBERG*),

Professor of Ophthalmology in King's College Hospital, &c.

A TREATISE ON DISEASES OF THE EYE. Third American,

from the Third London Edition. Thoroughly revised, with copious additions, by Chas. S. Bull, M D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with about 250 engravings on wood, and six colored plates. Together with selections from the Test-types of Jaeger and Snellen. In one large and very handsome octavo volume of 900 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6.50. (*Just Ready.*)

The long-continued illness of the author, with its fatal termination, has kept this work for some time out of print, and has deprived it of the advantage of the revision which he sought to give it during the last years of his life. This edition has therefore been placed under the editorial supervision of Dr. Bull, who has labored earnestly to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision. To accomplish this, considerable additions have been required, and the work is now presented in the confidence that it will fully deserve a continuance of the very marked favor with which it has hitherto been greeted as a complete, but concise, exposition of the principles and facts of its important department of medical science.

The additions made in the previous American editions by Dr. Hays have been retained, including the very full series of illustrations and the test-types of Jaeger and Snellen.

This new edition of Dr. Wells's great work on the eye will be welcomed by the profession at large as well as by the oculist. It contains much new matter relating to treatment and pathology, and is brought thoroughly up with the present status of ophthalmology. Its chapter on refraction and accommodation—a subject much discussed of late years, and of great importance—is exceedingly complete.—*Louisville Med. News*, Nov. 13, 1880.

The merits of Wells's treatise on diseases of the eye have been so universally acknowledged, and are so familiar to all who profess to have given any attention to ophthalmic surgery, that any discussion of them at this late day will be a work of supererogation. Very little that is practically useful in recent ophthalmic literature has escaped the editor, and the third American edition is well up to the times. As a text-book on ophthalmic surgery for the English speaking practitioner, it is without a rival.—*Am. Journ. of Med. Sci.*, Jan. 1881.

The work has justly held a high place in English ophthalmic literature, and at the time of its first appearance was the best treatise of its kind in the language. In the second edition, the author showed industrious research in adding new material from every quarter, and his spirit was eminently candid. A work thus built up by honest effort should not be suffered to die, and we are pleased to receive this third edition from the hands of Dr. Bull. His labor has been arduous, as the very great number of additions bracketed with his initial testify. Under the editorship which the third edition has enjoyed, the work is sure to sustain its good reputation, and to maintain its usefulness.—*N. Y. Med. Journ.*, Jan. 1881.

There is really no work which approaches it in adaptation to the wants of the general practitioner, while the most advanced specialist cannot rise from a perusal of its ample pages without having added to his knowledge. The American editor, Dr. Bull, won his spurs in ophthalmology some time back. His additions to the work of the lamented Wells are many, judicious, and timely, and in just so much have added to its value.—*Am. Practitioner*, Jan. 1881.

NETTLESHIP (*EDWARD*), *F.R.C.S.*,

Ophthalmic Surg. and Lect. on Ophth. Surg. at St. Thomas' Hospital, London.

MANUAL OF OPHTHALMIC MEDICINE. In one royal 12mo.

volume of over 350 pages, with 89 illustrations. Cloth, $2. (*Just Ready.*)

The author is to be congratulated upon the very successful manner in which he has accomplished his task; he has succeeded in being concise without sacrificing clearness, and, including the whole ground covered by more voluminous text-books, has given an excellent *résumé* of all the practical information they contain. We do not hesitate to pronounce Mr Nettleship's book the best manual on ophthalmic surgery for the use of students and "busy practitioners" with which we are acquainted.—*Am. Jour. Med. Sciences*, April, 1880.

CARTER (*R. BRUDENELL*), *F.R.C.S.*,

Ophthalmic Surgeon to St. George's Hospital, etc.

A PRACTICAL TREATISE ON DISEASES OF THE EYE. Edited,

with test-types and Additions, by JOHN GREEN, M.D. (of St. Louis, Mo.). In one handsome octavo volume of about 500 pages, and 124 illustrations. Cloth, $3 75. (*Just Issued.*)

It is with great pleasure that we can endorse the work as a most valuable contribution to practical ophthalmology. Mr. Carter never deviates from the end he has in view, and presents the subject in a clear and concise manner, easy of comprehension, and hence the more valuable. We would especially commend, however, as worthy of high praise, the manner in which the therapeutics of disease of the eye is elaborated, for here the author is particularly clear and practical, where other writers are unfortunately too often deficient. The final chapter is devoted to a discussion of the uses and selection of spectacles, and is admirably compact, plain, and useful, especially the paragraphs on the treatment of presbyopia and myopia. In conclusion, our thanks are due the author for many useful hints in the great subject of ophthalmic surgery and therapeutics, a field where of late years we glean but a few grains of sound wheat from a mass of chaff.—*New York Medical Record*, Oct. 23, 1875.

BROWNE (*EDGAR A.*),

Surgeon to the Liverpool Eye and Ear Infirmary, and to the Dispensary for Skin Diseases.

HOW TO USE THE OPHTHALMOSCOPE. Being Elementary In-

structions in Ophthalmoscopy, arranged for the Use of Students. With thirty-five illustrations. In one small volume royal 12mo. of 120 pages: cloth, $1. (*Now Ready.*)

LAURENCE'S HANDY-BOOK OF OPHTHALMIC SURGERY, for the use of Practitioners. Second edition, revised and enlarged With numerous illustrations. In one very handsome octavo volume, cloth, $2 75.

LAWSON'S INJURIES TO THE EYE, ORBIT, AND EYELIDS: their Immediate and Remote Effects. With about one hundred illustrations. In one very handsome octavo volume, cloth, $3 50.

BURNETT (CHARLES H.), M.A., M.D.,

Aural Surg. to the Presb. Hosp., Surgeon-in-charge of the Infir. for Dis. of the Ear, Phila.

THE EAR, ITS ANATOMY, PHYSIOLOGY, AND DISEASES.

A Practical Treatise for the Use of Medical Students and Practitioners. In one handsome octavo volume of 615 pages, with eighty-seven illustrations: cloth, $4 50; leather, $5 50; half Russia, $6 00. (*Now Ready.*)

Foremost among the numerous recent contributions to aural literature will be ranked this work of Dr. Burnett. It is impossible to do justice to this volume of over 600 pages in a necessarily brief notice. It must suffice to add that the book is profusely and accurately illustrated, the references are conscientiously acknowledged, while the result has been to produce a treatise which will henceforth rank with the classic writings of Wilde and Von Tröltsch.—*The Lond. Practitioner*, May, 1879.

On account of the great advances which have been made of late years in otology, and of the increased interest manifested in it, the medical profession will welcome this new work, which presents clearly and concisely its present aspect, whilst clearly indicating the direction in which further researches can be most profitably carried on. Dr. Burnett from his own matured experience, and availing himself of the observations and discoveries of others, has produced a work which, as a text-book, stands *facile princeps* in our language. We had marked several passages as well worthy of quotation and the attention of the general practitioner, but their number and the space at our command forbid. Perhaps it is better, as the book ought to be in the hands of every medical student, and its study will well repay the busy practitioner in the pleasure he will derive from the agreeable style in which many otherwise dry and mostly unknown subjects are treated. To the specialist the work is of the highest value, and his sense of gratitude to Dr. Burnett will, we hope, be proportionate to the amount of benefit he can obtain from the careful study of the book, and a constant reference to its trustworthy pages.—*Edinburgh Med. Jour.*, Aug. 1878.

TAYLOR (ALFRED S.), M.D.,

Lecturer on Med. Jurisp. and Chemistry in Guy's Hospital.

A MANUAL OF MEDICAL JURISPRUDENCE. Eighth American edition.

Thoroughly revised and rewritten. Edited by JOHN J. REESE, M.D., Prof. of Med. Jurisp. and Toxicology in the Univ. of Penn. In one large octavo volume of 933 pages. Cloth, $5; leather, $6; half Russia, raised bands, $6 50. (*Just Ready*)

The American editions of this standard manual have for a long time laid claim to the attention of the profession in this country; and that the profession has recognized this claim with favor is proven by the call for frequent new editions of the work. This one, the eighth, comes before us as embodying the latest thoughts and emendations of Dr. Taylor, upon the subject to which he devoted his life, with an assiduity and success which made him *facile princeps* among English writers on medical jurisprudence. Both the author and the book have made a mark too deep to be affected by criticism, whether it be censure or praise. In this case, however, we should only have to seek for laudatory terms.—*Am. Journ. of Med. Sci.*, Jan. 1881.

It is not very often that a medical book reaches its tenth edition, or that the last earthly labor is performed by the author in retouching the work that first came from his hand thirty-five years before. All this, however, has happened in the case of Dr. Taylor and his classical treatise. The pen dropped from the grasp only when the shadows of old age were rapidly deepening into the darkness of death. Under the circumstances, all the journalist has to do is to announce, not criticize the completed task. The value of the gem is too well known to require more than the telling that the master-hand has relrighened its facets and polished its angles before leaving it as his legacy to his brethren in the profession.—*Phila Med. Times*, Dec. 4, 1880.

It will suffice to remark that this new edition shows the signs of judicious revision. A great number of illustrative medico-legal cases which have occurred since the last edition was published are cited in their proper connection, and add much to the interest and value of the work; they comprise the bulk of the additions to the text. As an indication of the freshness of the work, we notice numerous references to medico-legal experience that has transpired during the year just ended; among these is a comment by the American editor upon that midsummer madness, the Tanner fasting exploit of last August. In these features and in others there is ample evidence that this admirable book will maintain its high place as a standard authority concerning the matters of which it treats.—*Boston Med. and Surg. Journal*, Jan. 13, 1881.

BY THE SAME AUTHOR.

THE PRINCIPLES AND PRACTICE OF MEDICAL JURISPRUDENCE.

Second Edition, Revised, with numerous Illustrations. In two large octavo volumes, cloth, $10 00; leather, $12 00

This great work is now recognised in England as the fullest and most authoritative treatise on every department of its important subject. In laying it, in its improved form, before the American profession, the publishers trust that it will assume the same position in this country.

BY THE SAME AUTHOR.

POISONS IN RELATION TO MEDICAL JURISPRUDENCE AND MEDICINE.

Third American, from the Third and Revised English Edition. In one large octavo volume of 850 pages; cloth, $5 50; leather, $6 50. (*Just Issued.*)

The present is based upon the two previous editions; "but the complete revision rendered necessary by time has converted it into a new work." This statement from the preface contains all that it is desired to know in reference to the new edition. The works of this author are already in the library of every physician who is liable to be called upon for medico-legal testimony (and what one is not?), so that all that is required to be known about the present book is that the author has kept it abreast with the times. What makes it now, as always, especially valuable to the practitioner is its conciseness and practical character, only those poisonous substances being described which give rise to legal investigations.—*The Clinic*, Nov. 6, 1875.

Dr. Taylor has brought to bear on the compilation of this volume, stores of learning, experience, and practical acquaintance with his subject, probably far beyond what any other living authority on toxicology could have amassed or utilized. He has fully sustained his reputation by the consummate skill and legal acumen he has displayed in the arrangement of the subject-matter, and the result is a work on Poisons which will be indispensable to every student or practitioner in law and medicine.—*The Dublin Journ. of Med Sci.*, Oct. 1875.

ROBERTS (WILLIAM), M.D.,
Lecturer on Medicine in the Manchester School of Medicine, etc.

A PRACTICAL TREATISE ON URINARY AND RENAL DISEASES, including Urinary Deposits. Illustrated by numerous cases and engravings. Third American, from the Third Revised and Enlarged London Edition. In one large and handsome octavo volume of over 600 pages. Cloth, $4. (*Just Ready.*)

THOMPSON (SIR HENRY),
Surgeon and Professor of Clinical Surgery to University College Hospital.

LECTURES ON DISEASES OF THE URINARY ORGANS. With illustrations on wood. Second American from the Third English Edition. In one neat octavo volume. Cloth, $2 25. (*Just Issued.*)

BY THE SAME AUTHOR.

ON THE PATHOLOGY AND TREATMENT OF STRICTURE OF THE URETHRA AND URINARY FISTULÆ. With plates and wood-cuts. From the third and revised English edition. In one very handsome octavo volume, cloth, $3 50. (*Lately Published.*)

TUKE (DANIEL HACK), M.D.,
Joint author of The Manual of Psychological Medicine, &c.

ILLUSTRATIONS OF THE INFLUENCE OF THE MIND UPON THE BODY IN HEALTH AND DISEASE. Designed to illustrate the Action of the Imagination. In one handsome octavo volume of 416 pages, cloth, $3 25. (*Lately Issued.*)

BLANDFORD (G. FIELDING), M.D., F.R.C.P.,
Lecturer on Psychological Medicine at the School of St. George's Hospital, &c.

INSANITY AND ITS TREATMENT: Lectures on the Treatment, Medical and Legal, of Insane Patients. With a Summary of the Laws in force in the United States on the Confinement of the Insane. By ISAAC RAY, M. D. In one very handsome octavo volume of 471 pages; cloth, $3 25.

It satisfies a want which must have been sorely felt by the busy general practitioners of this country. It takes the form of a manual of clinical description of the various forms of insanity, with a description of the mode of examining persons suspected of insanity. We call particular attention to this feature of the book, as giving it a unique value to the general practitioner. If we pass from theoretical considerations to descriptions of the varieties of insanity as actually seen in practice and the appropriate treatment for them, we find in Dr. Blandford's work a considerable advance over previous writings on the subject. His pictures of the various forms of mental disease are so clear and good that no reader can fail to be struck with their superiority to those given in ordinary manuals in the English language or (so far as our own reading extends) in any other.—*London Practitioner*, Feb. 1871.

LEA (HENRY C.).

SUPERSTITION AND FORCE: ESSAYS ON THE WAGER OF LAW, THE WAGER OF BATTLE, THE ORDEAL, AND TORTURE. Third Revised and Enlarged Edition. In one handsome royal 12mo. volume of 552 pages. Cloth, $2 50. (*Just Ready.*)

This valuable work is in reality a history of civilization as interpreted by the progress of jurisprudence. . . . In "Superstition and Force" we have a philosophic survey of the long period intervening between primitive barbarity and civilized enlightenment. There is not a chapter in the work that should not be most carefully studied, and however well versed the reader may be in the science of jurisprudence, he will find much in Mr. Lea's volume of which he was previously ignorant. The book is a valuable addition to the literature of social science.—*Westminster Review*, Jan. 1880.

The appearance of a new edition of Mr. Henry C. Lea's "Superstition and Force" is a sign that our highest scholarship is not without honor in its native country. Mr. Lea has met every fresh demand for his work with a careful revision of it, and the present edition is not only fuller and, if possible, more accurate than either of the preceding, but, from the thorough elaboration is more like a harmonious concert and less like a batch of studies.—*The Nation*, Aug. 1, 1878.

Many will be tempted to say that this, like the "Decline and Fall," is one of the uncriticizable books. Its facts are innumerable, its deductions simple and inevitable, and its *chevaux-de-frise* of references bristling and dense enough to make the keenest, stoutest, and best equipped assailant think twice before advancing. Nor is there anything controversial in it to provoke assault. The author is no polemic. Though he obviously feels and thinks strongly, he succeeds in attaining impartiality. Whether looked on as a picture or a mirror, a work such as this has a lasting value.—*Lippincott's Magazine*, Oct. 1878.

BY THE SAME AUTHOR.

STUDIES IN CHURCH HISTORY. THE RISE OF THE TEMPORAL POWER—BENEFIT OF CLERGY—EXCOMMUNICATION. In one large royal 12mo. volume of 516 pp.; cloth, $2 75. (*Lately Published.*)

The story was never told more calmly or with greater learning or wiser thought. We doubt, indeed, if any other study of this field can be compared with this for clearness, accuracy, and power.—*Chicago Examiner*, Dec. 1870.

Mr. Lea's latest work, "Studies in Church History," fully sustains the promise of the first. It deals with three subjects—the Temporal Power, Benefit of Clergy, and Excommunication, the record of which has a peculiar importance for the English student, and is a chapter on Ancient Law likely to be regarded as final. We can hardly pass from our mention of such works as these—with which that on "Sacerdotal Celibacy" should be included—without noting the literary phenomenon that the head of one of the first American houses is also the writer of some of its most original books.—*London Athenæum*, Jan. 7, 1871.

HENRY C. LEA'S SON & CO.—Philadelphia.

WELLS ON THE EYE—New Edition—Just Ready.

A TREATISE ON DISEASES OF THE EYE. By J. Soelberg Wells, late Professor of Ophthalmology in King's College Hospital. Third American, from the Third English edition. Thoroughly revised with copious notes and additions. By Charles S. Bull, M.D., Surgeon and Pathologist to the New York Eye and Ear Infirmary. Illustrated with over 250 engravings on wood and six colored plates, together with selections from the test-types of Jaeger and Snellen. In one large and very handsome octavo volume of 900 pages. Cloth, $5; leather, $6; very handsome half Russia, raised bands, $6 50.

It is with great pleasure that we welcome a new edition of this standard work on ophthalmology. The American editor has taken great pains to introduce in it all the advances which observation and experience have acquired for the theory and practice of ophthalmology since the appearance of the last revision in 873. - *Philadelphia Med. and Surg. Reporter*, Oct. 23, 1880.

This new edition of Dr. Wells's great work on the eye will be welcomed by the profession at large as well as by the oculist. It contains much new matter relating to treatment and pathology, and is brought thoroughly up with the present status of ophthalmology. Its chapter on refraction and accommodation—a subject much discussed of late years, and of great importance—is exceedingly complete.—*Louisville Med. News*, Nov. 13, 1880.

We congratulate the editor upon having done his work so well, and the medical public in having so valuable a text-book brought down to date.—*Archives of Medicine*, April, 1881.

We have no hesitation in recommending it to the readers of the *Record* as the best English work on ophthalmology.—*St. Louis Clin. Record*, Dec. 1880.

BUMSTEAD ON VENEREAL DISEASES—New Edition—Now Ready.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES. Including the results of recent investigations upon the subject. By Freeman J. Bumstead, M.D., LL.D., late Professor of Venereal Diseases at the Coll. of Phys. and Surg., New York, etc. Fourth edition, revised and largely rewritten with the co-operation of R. W. Taylor, M.D., of New York, Prof. of Dermatology in the Univ. of Vermont. In one large and handsome 8vo. volume of 835 pages, with 138 illustrations. Cloth, $4 75; leather, $5 75; very handsome half Russia, raised bands, $6 25.

The present edition of Dr. Bumstead's well-known treatise on venereal diseases has been almost entirely rewritten, with the co-operation of Dr. Taylor. It is needless to enter into the numerous features of this work It is, beyond question, the most complete and accurate book on the subject in any language, and one which ought to be in the hands of every one who has much to do with syphilitic diseases.—*Lond. Med. Times and Gaz.*, Dec. 11, 1880.

The treatise has lost nothing by the addition of the advanced views, the active brain, and the industrious pen of the new co-editor, whose aim has been, through "bringing the volume up to date, by including all affections thus far known in the shortest and clearest manner, to present a book worthy of the American medical profession."—*Boston Med. and Surg. Journal*, Jan. 1880.

FOTHERGILL'S HANDBOOK OF TREATMENT—Second Edition—Just Ready.

THE PRACTITIONER'S HANDBOOK OF TREATMENT; or, The Principles of Therapeutics. By J. Milner Fothergill, M.D. Edinb., M.R.C.P Lond., Asst. Physician to the West London Hospital; Asst. Physician to the City of London Hospital, etc. Second Edition, revised and enlarged. In one very neat octavo volume of about 650 pages. Cloth, $4; very handsome half Russia, raised bands, $5.50.

The author merits the thanks of every well-educated physician for his efforts toward rationalizing the treatment of diseases upon the scientific basis of physiology. Every chapter, every line, has the impress of a master hand, and while the work is thoroughly scientific in every particular, it presents to the thoughtful reader all the charms and beauties of a well-written novel No physician can well afford to be without this valuable work, for its originality makes it fill a niche in medical literature hitherto vacant.—*Nashville Journal of Med. and Surg.*, Oct. 1880.

CLOWES' CHEMISTRY—New Edition—Just Ready.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS By Frank Clowes, D.Sc. London, Senior Science Master at the High School, Newcastle-under-Lyme. Specially adapted for use in the Laboratories of Schools and Colleges, and by Beginners. Second American, from the Third and Revised English edition, with about 50 illustrations on wood. In one very handsome royal 12mo. volume of 372 pages. Cloth, $2 50.

This is a valuable work for those about to commence chemistry, the more so as by its use they are simultaneously acquainted with the manipulation of chemical analysis, a method which is the most valuable to impart a thorough knowledge of chemistry. It is a very good little book, and will make for itself many warm friends and supporters. It treats the subject well, and the tables are very clear and valuable.—*St. Louis Med. and Surg. Journal*, March, 1881.

CORNIL & RANVIER'S PATHOLOGICAL HISTOLOGY—Now Ready.

MANUAL OF PATHOLOGICAL HISTOLOGY. By V. Cornil, Prof. in the Faculty of Medicine, Paris, and L. Ranvier, Prof. in the College of France. Translated, with Notes and Additions, by E. O. Shakespeare, M.D., Pathologist and Ophthalmic Surgeon to Philada. Hospital, Lecturer on Refraction and Operative Ophthalmic Surgery in Univ. of Pa., and by J. Henry C. Simes, M.D., Demonstrator of Pathological Histology in the Univ. of Pa. In one very handsome octavo volume of over 700 pages, with over 350 illustrations. Cloth, $5 50; leather, $6 50; very handsome half Russia, raised bands, $7.

This volume we cordially commend to the profession. It will prove a valuable, almost necessary, addition to the libraries of students who are to be physicians, and to the libraries of students who are physicians.—*American Practitioner*, June, 1880.

We have no hesitation in cordially recommending the English translation of Cornil & Ranvier's "Pathological Histology," as the best work of the kind in any language, and as giving to its readers a trustworthy guide in obtaining a broad and solid basis for the appreciation of the practical bearings of pathological anatomy.—*Am. Journ. of Med. Sciences*, April, 1880.

HENRY C. LEA'S SON & CO., Philadelphia.

PROSPECTUS FOR 1881.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES.

In commencing its sixty-first year, the publishers of the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES" have much pleasure in assuring its wide circle of readers that at no period has it had the prospect of a more extended field of usefulness.

For 1881 the "American Journal" has the promise of its usual variety of important contributions from distinguished members of the profession in all parts of the country. Special attention will be bestowed, as heretofore, on its Bibliographical Department and Quarterly Summaries to keep its subscribers informed as to all subjects of professional interest from every quarter.

With its attendant periodical, "THE MEDICAL NEWS AND ABSTRACT," it combines the advantages of the elaborate preparation which can be given to a quarterly, and the prompt conveyance of intelligence by the monthly, while, the whole being under a single editorial supervision, the subscriber is secured against the duplication of matter inevitable under other circumstances. These efforts the publishers seek to second by offering these periodicals at a price unprecedentedly low—a price which places them within the reach of every practitioner, and gives the equivalent of three large octavo volumes for the comparatively trifling cost of FIVE DOLLARS *per annum*.

The "NEWS AND ABSTRACT" consists of sixty-four pages monthly, in a neat cover. It contains a CLINICAL DEPARTMENT in which will be continued the series of ORIGINAL AMERICAN CLINICAL LECTURES, contributed by gentlemen of the highest reputation throughout the United States, together with a choice selection of Foreign Lectures and Hospital Notes and Gleanings. Then follows the "MONTHLY ABSTRACT," systematically arranged and classified, and presenting five or six hundred articles yearly; each number concluding with an EDITORIAL and a NEWS DEPARTMENT, giving current professional intelligence, domestic and foreign, the whole fully indexed at the close of each volume, rendering it of permanent value for reference.

The subscription price to the "NEWS AND ABSTRACT" will be Two Dollars and a Half per annum, invariably in advance, at which rate it will rank as one of the cheapest medical periodicals in the country. But it will also be furnished, free of all charge, in commutation with the "AMERICAN JOURNAL OF THE MEDICAL SCIENCES," to all who remit FIVE DOLLARS in advance, thus giving to the subscriber, for that very moderate sum, a complete record of medical progress throughout the world, in the compass of about two thousand large octavo pages.

These terms may be recapitulated as follows:—

TERMS FOR 1881.

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, published quarterly (1150 pages per annum), and The MEDICAL NEWS AND ABSTRACT, published monthly (768 pages per annum),	Five Dollars per annum, in advance.

SEPARATE SUBSCRIPTIONS TO

The AMERICAN JOURNAL OF THE MEDICAL SCIENCES, when not paid for in advance,	Five Dollars.
The MEDICAL NEWS AND ABSTRACT, invariably in advance,	Two Dollars and a Half.

*** Advance-paying subscribers can obtain, at the close of the year, cloth covers, gilt lettered, for binding the volumes of the JOURNAL (two annually) and the NEWS AND ABSTRACT (one annually), free by mail, on remitting ten cents for each cover.

The safest mode of remittance is by bank check or draft, or postal money order drawn to the order of the undersigned. Where these are not accessible, remittances for the "JOURNAL" and "NEWS AND ABSTRACT" may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

NEW MEDICAL WORKS.

BARTHOLOW ON ELECTRICITY—Just Ready.

A PRACTICAL TREATISE ON ELECTRICITY IN ITS APPLICATIONS TO MEDICIN
By Roberts Bartholow, A.M., M.D., LL.D., Professor of Materia Medica and Gene
Therapeutics in the Jefferson Medical College of Philadelphia. In one very handso
octavo volume of about 300 pages, with 96 illustrations. Cloth, $2 50.

EXTRACT FROM AUTHOR'S PREFACE.

"In my annual course of lectures on Materia Medica and Therapeutics, I have discussed m
or less fully the subject of medical electricity as a therapeutical agent. It happened in this
that my attention was called to the need of a suitable text-book. That there are excell
works on medical electricity is undeniable, but some of them are too voluminous, others
scientific, and not a few wanting in both fulness and accuracy. I have attempted, in the pr
aration of this work, to avoid these errors; to prepare one so simple in statement that a stude
without previous acquaintance with the subject, may readily master the essentials; so compl
as to embrace the whole subject of medical electricity, and so condensed as to be complete
a moderate compass. I have endeavored to keep constantly in view the needs of the two cla
for whom the work is prepared—students and practitioners. I have assumed an entire u
quaintance with the elements of the subject at the point of departure, for I am addressing th
who have either failed to acquire this preliminary knowledge, or having acquired it, find t
after the lapse of years, it has become misty and confused. In the account of electrical p
nomena, I have adhered to the modes of expression with which the medical electrical t
books have made us familiar.

"This book, then, must be regarded as the exposition of electricity as a remedial agent, m
by a medical practitioner for the use of medical practitioners. No claim is made on the gro
of pure science. It is believed, however, that the work makes an adequate presentation of
subject, regarding electricity as a remedial agent—as one of the means employed for the tr
ment and cure of disease."

MITCHELL ON DISEASES OF THE NERVOUS SYSTEM—Just Ready.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, ESPECIALLY IN WOMEN.
S. Weir Mitchell, M.D., Physician to the Orthopædic Hospital and Infirmary for
eases of the Nervous System. In one very handsome 12mo. volume of 238 pages, with
lithographic plates. Extra cloth, $1 75.

GROSS ON STERILITY—In Press.

A PRACTICAL TREATISE ON IMPOTENCE, STERILITY, AND ALLIED DISORDE
OF THE MALE SEXUAL ORGANS. By Samuel W. Gross, A.M., M.D., Lecturer
Genito-Urinary and Venereal Diseases in the Jefferson Medical College, Philada. In
handsome octavo volume, with illustrations.

MAISCH'S MATERIA MEDICA—Preparing.

A MANUAL OF MATERIA MEDICA. Being a Guide to Materia Medica of the Vegeta
and Animal Kingdoms. For the use of Students, Druggists, Pharmacists and Physicia
By John M. Maisch, Phar. D., Professor of Materia Medica and Botany in the Phila
College of Pharmacy. In one handsome 12mo. vol., with numerous illustrations on wo

PARVIN'S MIDWIFERY—Preparing.

A TREATISE ON MIDWIFERY. By Theophilus Parvin, M.D., Prof. of Obstetrics
the Medical and Surgical Diseases of Women in the Medical College of Indiana. In
very handsome octavo volume of about 550 pages, with numerous illustrations.

WOODBURY'S HANDBOOK OF PRACTICE—Preparing.

A HANDBOOK OF THE PRINCIPLES AND PRACTICE OF MEDICINE. For the
of Students and Practitioners of Medicine. By Frank Woodbury, M.D., Physician
the German Hospital, Philada., late Chief Assistant to the Medical Clinic of Jeff. Coll
Hospital, Philada. In one handsome 12mo. volume.

SMITH ON CHILDREN—New Edition—Preparing.

A COMPLETE PRACTICAL TREATISE ON THE DISEASES OF CHILDREN. By
Lewis Smith, M.D., Clinical Professor of Diseases of Children in the Bellevue Hosp
Medical College, New York. Fifth edition, thoroughly revised and rewritten. In
handsome octavo volume of about 800 pages, with illustrations.

CLINICS.

Clinical Lectures.

ON THE TREATMENT OF TYPHOID FEVER.

AN ADDRESS DELIVERED BEFORE THE KENTUCKY STATE MEDICAL SOCIETY, APRIL 8, 1881.

BY L. S. McMURTRY, A.M., M.D.,
OF DANVILLE, KENTUCKY.

MR. PRESIDENT AND GENTLEMEN: In discussing the subject of the treatment of typhoid fever, I can lay no claim to your attention from novelty of views or of practice, but only from the intrinsic importance of the subject. It is a well-known fact that in the rural districts of our State, epidemics of this disease are so rare of late years that one is almost justified in the assertion that epidemic typhoid fever in this locality is extinct. Twenty years ago the disease prevailed in epidemic form throughout the villages and farming districts of this State almost every season with frightful severity. Now we rarely encounter typhoid fever except in isolated cases in which the disease was contracted elsewhere and brought home in the formative stage. It may be assumed upon the highest authority that typhoid fever is never of spontaneous origin, that the disease is produced by a specific poison, and that this poison always comes from one suffering with this specific fever. It is a well-known fact that the most common medium of communication and dissemination of the disease is drinking water. Formerly wells with free sub-soil communication were the sources of drinking water. Now cisterns are the almost universal sources of water supply in Kentucky. The geological formation is admirably adapted to the construction of cisterns, and the cemented cisterns of this State are practically sealed bottles into which water pours through filters. That to this improved supply of drinking water, together with the care given by modern physicians to the disposal and disinfection of the dejections of typhoid patients, is due the immunity in this region from epidemics of typhoid fever, there seems to be no reasonable doubt.

Nevertheless there is scarcely a year that passes that every general practitioner among us is not called upon to treat several cases of typhoid fever. The natural history is of such long duration, and the balance between life and death so evenly poised, that the management of this malady must at all times command most careful and thoughtful attention.

The unsettled state of professional opinion as to the management of the disease is indicated by the diversity of views and practice among those best qualified by clinical experience to judge of the efficacy of the several plans of treatment. And it must be observed that the two methods of treatment most prominently advocated at the present time are in their essentials and details so diametrically opposed to each other, that one is compelled to decide between the two, and adopt a method of practice either somewhat heroic or altogether expectant. The care of several cases of typhoid during the past summer and autumn has directed my attention particularly to the consideration of the methods of treatment now before the profession, and has for the time at least invested the subject with peculiar interest.

The publication in this country of Niemeyer's work on the "Practice of Medicine," and more recently of Ziemssen's "Cyclopædia," has brought authoritatively to the attention of American physicians the method of treatment known among us as the German method. This treatment is based upon the existence of specific remedies for the disease, the remedies to which such power is attributed being calomel and iodine. In the early stage of the disease, when in the majority of cases treatment is instituted, calomel is according to this method to be administered in doses of half a scruple, and the remedy repeated in similar doses four times in twenty-four hours. Iodine is also to be given in the form of Lugol's solution or iodide of potassium, so that from a scruple to a drachm of the latter is given in twenty-four hours. According to this method calomel is administered daily, or on alternate days during the first week; and the iodine is continued over two weeks, or until the beginning of convalescence. Beyond the use of these remedies the main feature of this method of treatment is depressing the temperature by active measures. It is assumed that the greatest danger to the patient lies in the injury done the tissues by the fever heat. It is claimed that the danger is in the parenchymatous degeneration which results from a high and prolonged elevation of temperature. The remedies resorted to for reducing temperature in this disease are hydrotherapy, quinia, and digitalis. The cold bath alone may be applied and repeated until the temperature is reduced, or quinia may be administered in scruple doses every four hours until this result is obtained, or the cold bath, quinia and digitalis, all in conjunction may be resorted to for the desired result. This so-called specific method is advocated in one of the most recent and best of our American books on practical medicine,[1] while the antipyretic measures mentioned are advocated in whole or in part by various authorities in Great Britain and America. The Croonian Lectures for 1880[2] are essentially devoted to the advocacy of treating this disease by the fearless exhibition of the antipyretic method particularly as to cold baths.

There are two methods of estimating the efficacy of various plans of treating a given disease, consisting of the analysis of results from the numerical record of cases; and the testimony of individuals based on pathological study together with clinical experience. In the former, the statistical method, the circumstances of the patient, accuracy in diagnosis, and skill in treatment, are such variable elements as to greatly impair the reliability of the deductions made. A careful investigation of the etiology

[1] The Practice of Medicine, by Roberts Bartholow, M.A., M.D., p. 701.
[2] On Some Points in the Pathology and Treatment of Typhoid Fever, by Wm. Cayley, M.D., F.R.C.P. London, 1880.

and pathology of the disease, aided by clinical observation, must at last be the guide to individual views and practice.

Until the mechanism of fever is accurately determined, and it is demonstrated that elevation of temperature produces effects alike or uniform in character, the antipyretic treatment of fevers is without a secure foundation in theory, and until the results of this method are more eminently superior it will not be generally adopted in practice. At a recent meeting of the Metropolitan Counties Branch of the British Medical Association, the utility of cold baths in treating typhoid fever was quite thoroughly discussed. It was demonstrated that this method of treatment is not in general favour, and that it is by no means an established therapeutic measure in England. In America it has not met with favour, and occupies a very questionable place in practical therapeutics. Indeed, the more conservative methods of treating the disease are gaining in favour and confidence both in this country and Great Britain.

There are certain established facts in the etiology and pathology of typhoid fever which furnish the only trustworthy guides to the management of the disease. The most important of these are that the disease results from the introduction into the system of a specific poison; that when the poison is once lodged in the system all the stages of the disease are inevitable and must be encountered before the patient can be well; that the natural history of the disease extends over a period of twenty-eight or thirty days and cannot be abbreviated; and that there are no known drugs or remedial measures by which the disease can be aborted, cut short, or cured. These facts being firmly established, that treatment is the best which looks to conserving the patient's strength, avoiding special complications and dangers, and keeping the patient alive until convalescence is reached.

At the onset of an attack of typhoid fever the patient must be protected from his own imprudence. He will almost invariably think that he is suffering from a cold or disordered digestion (biliousness), and will endeavour to throw off the headache and malaise by purgative medicines and exercise. As soon as the diagnosis is made, and in this the thermometer will furnish the best aid, the patient should be put to bed and given attention at once. The management of the case from this time may be considered under the following heads: (1) The Surroundings of the Patient; (2) Diet; (3) Medicines; (4) The Use of Stimulants; (5) The Use of Antipyretics. One who has seen much of typhoid fever cannot but feel the importance of minute details in its management. The course over which the patient must run presents so many dangers, and, at best, the balance is so evenly struck between a favourable and fatal issue, that an apparently trivial factor may determine the result. Hence the hygienic surroundings and psychological status of the patient become matters of serious import.

In the management of a case of typhoid fever the arrangement of the sick-room and surroundings of the patient are matters of the greatest importance, and must receive the personal attention of the physician. The room should be well ventilated, the light subdued, visitors excluded, and quietude maintained. During the first week of the disease the febrile action is high, and frontal headache and sleeplessness are the prominent symptoms. All causes of irritation must be obviated, and rest must be encouraged in every possible way. The surface of the body should be frequently sponged, and the bed and body linen changed every day. It is an excellent plan to also change the bed of the patient. During the hot

weather of last August I managed to restoration a case of the disease of more than average severity, in which the patient frequently occupied three beds in the course of twenty-four hours; the bed being rolled to the cool portion of a large hall in the morning, changing to the opposite side in the afternoon, and the patient changed to a fresh cool bed at convenient intervals. The services of a properly qualified nurse are of inestimable importance in the management of this disease.

The diet of typhoid patients requires the closest attention, and demands the utmost care and judgment. The specific lesions of the disease being in the alimentary canal, errors in diet produce injurious results which are immediate. The Peyerian patches and the solitary glands in the lower part of the small intestine are always the seat of important pathological changes in typhoid fever. During the first week of the disease the mucous membrane in the vicinity of the ileo-cæcal valve and surrounding these glands is hyperæmic and swollen. The glands become more elevated, and their surface assumes a dark-reddish colour; when in the second week by active cell development and multiplication the agminated and solitary glands are swollen, and the adjoining mucous membrane infiltrated with cells. By the end of the second week the ulcerative process is well advanced, and the typhoid ulcer is formed. Usually the sloughing and removal of the necrotic tissue take place during the third week of the disease. The loss of substance may extend to the deeper layer of the mucous membrane, or it may involve the muscular coat to a greater or less extent, and may extend to perforation of the intestinal wall. During the fourth week granulation of the ulcerated surfaces begins, and, under favourable circumstances, this process advances to cicatrization. With a knowledge of these lesions before us, it is evident that the food should be easy of digestion and unirritating to the bowel. The enfeeblement of the digestive and assimilative powers resulting from these glandular changes, renders the digestion of solid food impossible, while the arrest of the salivary, and probably the pancreatic, secretion which obtains, likewise excludes starchy materials from the diet. The article of diet most efficient and capable in repairing the rapid waste of tissue which characterizes the disease is milk. We not only have in this article the essential elements of nutrition, but they are in the form and condition to be most readily and easily assimilated. If the stomach is irritable, lime-water may be added to the milk. Chicken broth, beef-tea, eggs, meat essences, and arrowroot are among the articles in common use, but all are inferior to milk. It is a common observation that persons who object to milk in health find it acceptable in this disease. Beef-tea and meat essences are not well tolerated by a healthy stomach, and hence are not suitable articles of diet for typhoid fever patients. Milk is *the article* of diet in typhoid fever, and should be given, according to the circumstances of the case, in small quantities every two, three, or four hours, so that three or four pints are taken in twenty-four hours. With the advent of convalescence comes an appetite which develops into a lust for food. Relapses at this stage of the disease are frequent, and it should be remembered that intestinal irritation, diarrhœa, hemorrhage, and perforation may be induced by imprudence in diet during convalescence. Cream and the white of eggs may be added to the milk at this time, and when convalescence is well advanced bread and milk, and soup may be taken, afterwards allowing meats. The patient should have cold water freely throughout the disease.

I know of no intelligent physician familiar with the pathological char-

acter and clinical history of typhoid fever, who believes that there is any specific remedy for this disease. Indeed it is generally conceded that we have no antidote for the typhoid poison; that there is no remedy which will cut short or abort its course; and all that lies within our power is to treat the symptoms as they arise. In cases of average severity it often happens that no medicines are required for their successful management. During the past summer I managed to recovery a case of typhoid, the patient being a robust young man, in which two small doses of chloral during the first week, and a bottle of white wine during convalescence, formed the sum total of all medicines used. Although we can neither neutralize nor eliminate the typhoid poison, yet we can in most cases control and relieve its most distressing and dangerous symptoms. Of these symptoms, diarrhœa is one of the most frequent, troublesome and dangerous. There are even now physicians eminent in the profession, who believe that the specific poison of the disease is eliminated by the bowels, and hence would encourage the diarrhœa by laxatives, and excite it by appropriate remedies if absent. As already described, the lesions of this disease impinge directly upon the alimentary canal, and the inflammation of the intestinal mucous membrane readily accounts for the intestinal catarrh. During the early period of the disease, the diarrhœa is not accompanied with much danger; but later in the disease, the increased peristalsis is an immediate danger to the diseased intestine. When brought on artificially, or when laxatives are used to relieve the constipation which is sometimes present, it is usually controlled only with great difficulty. For the control of this diarrhœa opium is the great remedy.

It must be borne in mind that our principal purpose in treating this condition, is to control the peristalsis of the bowel, rather than to check an increased discharge. Hence the indications for opium greatly exceed those for astringents.

As is well known, the large intestine may be torpid, and constipation result, while the small intestine is actively discharging its contents through the ileo-cæcal valve. This condition is indicated by constipation, with gurgling and griping over the small intestines. This state of the bowels, which apparently is the opposite one to diarrhœa, is best relieved by opium. It is a very rare combination of symptoms which will justify the use of cathartics in this disease. After the first week, should constipation demand attention, a simple enema will furnish the safest relief.

The use of antipyretic remedies—quinia and digitalis—has already been mentioned in detail. To these antipyretic remedies, the salicylate of soda has recently been added. Dr. Henry Tomkins, of Manchester, has recently set forth the value of this article as an antipyretic agent in typhoid fever; and since it is a powerful germicide, he gives it the first place in the list.[1] He administers the remedy in doses of fifteen or twenty grains every two hours, and usually finds six doses sufficient to bring the temperature within a safe range. Quinia in large and frequently repeated doses occupies a very favoured position as an antipyretic in the estimation of American physicians. The great objection to the use of these remedies is that the doses necessary for the antipyretic effect are so large as to be taken with extreme loathing on the part of the patient, and often materially interfere with nutrition by producing disturbances of the stomach.

Hemorrhage from the ulcerated surfaces of the bowel in typhoid fever

[1] *Vide* Lancet, March 12, 1881, p. 409.

is always an alarming symptom. It is by no means of infrequent occurrence. For the control of this condition opium is the one reliable remedy. The object is to place the bowel at rest, and it is doubtful if ergot, tannic acid, acetate of lead, or perchloride of iron, have the power to even give material aid to the control of this condition. If possible the exhibition of opium should be limited to enemata. Ice-cold drinks may be given freely and an ice-bag applied over the region of the ileum.

There is good authority for the statement that perforation of the bowel is always fatal. This accident is quickly followed by peritonitis, and the indications are to give opium freely and continuously.

Tympanites is often a very troublesome symptom in this disease. In all cases there is some distension by flatus, but frequently the accumulation of gas is so great as to interfere with the play of the diaphragm. This paralyzed condition of the bowel is the result of the intestinal ulceration. For the relief of this condition, turpentine has long been the standard remedy. It is administered internally, and applied to the abdomen in the form of stupes. To my mind the method of its action is not clear, and though familiar with its application for the relief of tympanites, I have never seen convincing evidence of its efficacy. Charcoal administered in small and frequently repeated doses is a more efficient remedy. Wishing, however, to do everything for the relief of a troublesome symptom, and knowing the confidence placed in turpentine for control of this condition by eminent practitioners, I would apply turpentine stupes over the abdomen when the tympanites becomes excessive and troublesome. The use of a cathartic at the beginning of the treatment, and the exhibition of calomel after the German method, beget intestinal commotion, increase the extent of the lesions, favour diarrhœa and intestinal and peritoneal complications. The indications for rest and preservation of the functions of the stomach should never be lost sight of throughout the management of the disease.

Respecting no single point is nicer discrimination required than the exhibition of alcohol in the treatment of this disease. Probably there is no one article capable of such great and good results when used in the proper time and emergency in typhoid fever, which has been so much abused. It must be remembered that the condition of a typhoid fever patient during the third and fourth week is very different from that of the earlier days of the disease. When about the beginning of the third week we find an irregular, rapid, and feeble pulse, accompanied with coolness of the surface and extremities, together with great exhaustion, we recognize this array of symptoms as indicating a failure of the power of the heart. This condition results not only from enfeebled muscular power, but also from altered and disturbed nerve influence. Together with these symptoms are often found a dry brownish tongue, tremor, and varying degrees of mental disturbance. For the relief of this condition alcohol is the remedy. Just at this stage is often the critical point in the disease, and the exhibition of alcohol may safely tide the patient over. When the use of stimulants is instituted the patient must be watched closely and examined every few hours. If the pulse becomes more distinct and regular; if the delirium is less active; the temperature lower; and the patient more in his right mind, we may be assured that the desired effect is being obtained. If, however, these symptoms are aggravated, the stimulants must be at once discontinued. When once instituted, stimulants must be given with regularity at fixed intervals. It must be kept in mind that stimulants may produce much

harm if given at the wrong period and in excessive quantity. It is rare that more than from four to eight ounces of whiskey or brandy are required in twenty-four hours. For the management of the greater number of cases of the disease, alcohol is not essentially required. The following words upon this point by Sir William Jenner, are full of wisdom: "For the last thirty years I have made it the rule of my practice in the treatment of typhoid fever, to abstain from giving alcohol if, in the case before me, I *doubted* the wisdom of giving it; when in doubt I do not give alcohol in typhoid fever, and when there is a question in my mind of a larger or smaller dose, I, as a rule, prescribe the smaller."[1]

Elevation of temperature is an essential part of the natural and uncomplicated history of typhoid fever. But when the temperature reaches 105° or 105.5°, and is disposed to advance or be continuous, we know that unless lowered the death of the patient will surely and speedily follow. Hence the theoretical ground for the antipyretic treatment of this disease has to this extent a foundation. I have already referred in detail to the antipyretics which are in use. There are many and serious obstacles to the general adoption of cold baths in practice. Indeed, in private practice, deprived of the conveniences and discipline of a hospital, together with the prejudice of the laity, it is almost impossible to carry out this treatment in all its details. But there are more serious obstacles to the general adoption of this method. There are strong indications that relapses are more frequent after this treatment, and that serious pulmonary lesions are caused by the baths. In the sulphate of quinia, exhibited in large doses, we have a reliable and efficient remedy for reducing temperature. This remedy, assisted by sponging the body with tepid water and the application of cold to the head and abdomen by means of the rubber tubing cap and ice-bags, will avert the danger of a high temperature when this is possible. Indeed, Liebermeister declares that, if compelled to choose between the use of cold water and quinia to reduce temperature in this disease, he would prefer the latter.[2]

I cannot better conclude the consideration of this important subject than to quote the expressions of two renowned and skilful practitioners. In a masterly address on the treatment of typhoid fever by Sir William Jenner, to which I have already referred, the following statement occurs:—

"While admitting without reserve that heroic measures, fearlessly but judiciously employed, will save life when less potent means are useless, the physician whose experience reaches over many years will, on looking back, discover that year by year he has seen fewer cases requiring heroic remedies, and more cases in which the unaided powers of nature alone suffice for effecting cure; that year by year he has learned to regard with greater diffidence his own powers, and to trust with greater confidence in those of nature."

The following is the language of Dr. John Syer Bristowe, the Senior Physician to St. Thomas's, London:—[3]

"Let me state briefly the treatment to which I should like to be subjected if ever, unfortunately, I should become affected with enteric fever: I should like to be placed in a cool well-ventilated room, and covered lightly with bed-clothes; to have a skilful and attentive nurse to look after me; to be fed solely with cold milk, unless vomiting should demand the addition to the milk of medicines calculated to allay vomiting. If diarrhœa became troublesome, or ever there was

much pain or tenderness in the cæcal region and in the bowels, I should like to be treated, not with laxatives, but with opium, given either by the mouth or by the rectum. If constipation were present, I should, except in the first week, like to have enemata only employed for its relief. In the event of intestinal hemorrhage coming on, I should like to have ice to suck or ice-cold fluids to drink, cold compresses to the belly, and cold injections into the bowel; and though I am sceptical as to their efficacy, I should still choose to have astringents, and more especially lead, given to me at short intervals. If perforation should take place, let me have large and repeated doses of opium. Stimulants I should prefer to be without early in the disease; later, however, and during convalescence, I should like to have them in moderation. As to cold baths, I would rather not have them; but I would, nevertheless, leave it to my physician to exercise his discretion in the matter. I would leave it also to him to decide, according to circumstances, whether alcohol should be administered to me in large quantities; I would prefer not to be treated at a temperance hospital."

ON A PUNCTURED WOUND OF THE SKULL.

A Clinical Lecture.

By J. W. HULKE, M.D.,
Surgeon to, and Lecturer on Surgery at, the Middlesex Hospital.

GENTLEMEN: Trephining in wounds of the skull, formerly so frequent, has now become so infrequent that most of you during the whole three years of your studentship will probably not see it done more than once or twice, and possibly not at all. It happens, however, that there are now in the wards two patients whom I have recently trephined, and to the case of one of these I now ask your attention.

The record by my dresser, Mr. Ed. Davis, is in effect as follows:—

Late in the afternoon of January 7 last a little flaxen-haired girl was taken into Bird ward suffering from the effects of a wound of the head. The child was quite conscious. She was remarkably quick and intelligent for her age, and she answered readily and pertinently questions put to her. Her face, very pale, was distorted by frequent spasms, which chiefly affected the mouth and the eyelids; both sides of the face appeared to be equally convulsed.

In the middle of the right parietal region was a small festering scalp-wound, through which the House-Surgeon had just before detected with a probe that the underlying bone was irregular as if broken, and slightly displaced.

The account given by the child's mother (which we had afterwards reason to think false) was that eleven days previously she had fallen off a low stool and cut her head by striking it against a fender. This stunned her for a little while, but she soon came to, and when the bleeding, which was inconsiderable, had ceased, the mother covered the cut with a piece of sticking-plaster. For two days the hair about the cut was wet with a watery oozing, and as the child seemed less lively than usual, on the third morning she was brought to the hospital surgery, where the junior House-Surgeon saw her. He found the cut had festered, and on taking off the plaster a couple of drops of pus escaped. Thinking it merely a superficial cut, it did not appear to him necessary to have the child admitted. Light Goulard-water dressing was put on, and the mother was told to bring her daily, which she did. Nothing unusual was noticed until the eleventh day after the accident, when at 4 P.M. the child had a fit, in which her left side "worked"

ore than her right; and when the fit was over she appeared to be in a deep eep. In great alarm the mother ran with her to the hospital, and, the gravity the case being apparent, she was instantly admitted. Her state at this time s just been told to you.

Throughout the evening her face was often convulsed, and at 11.30 P. M. a ttle difference of expression was first observed, suggestive of a slight degree of cial palsy. The child was also now noticed to take hold of anything offered to r exclusively with the right hand, and when trying to sit up in bed she sup-rted herself with this arm only, suggesting a slight degree of hemiplegia of the ft arm.

At 1 A. M. on January 8, facial palsy had become unmistakably marked, though t complete, and no doubt could be felt of the palsy of the left arm and hand; ith the right hand she grasped strongly and with precision, whilst the grasp of e left hand was feeble and faltering.

One hour later, at 2 A. M., the scalp was turned back from the bone at the ound, which exposed a small grayish button, apparently a puriformly softening t; and when this was detached, a circular hole in the parietal bone came into ew. It was as sharply cut as if it had been cut with a punch. The pericranium ound the margin of the hole for the breadth of about two inches was detached, ollen, and grayish. The parietal bone (the child being so young—four years d a half) was found to be so thin and elastic that it did not offer enough resist-ce to enable the teeth of the trephine to bite; the hole was therefore enlarged ith a cutting forceps, and whilst this was being done a little pus welled up from neath the bone. The grayish button had a stalk which passed through a sloughy gged hole in the dura mater. Exploring with a probe very cautiously through is hole for any splinters which might have been thrust in through the mem-anes, at the depth of about three-quarters of an inch from the surface some-ing hard was felt, and withdrawn with a slender forceps. It proved to be two eces of detached bone with hairs entangled around them. A little boric lint-arpie was now laid lightly on the wound, and fixed with a gauze capeline.

The temperature before the operation unfortunately was not recorded. During e first six hours afterwards it was subnormal, as these figures show—at 3 A. M., .2°; 4 A. M., 97.6°; 5 A. M., 97.2°; 6 A. M., 96.8°; 7 A. M., 98 4°; A. M., 97.0° Fahr.

At 10 A. M. the temperature was rising, and the pulse 112. The child was iet. The palsy of the face and left arm continued, and slight palsy of the left g was noticed.

At 11.30 A. M. the axillary temperature had risen to 101.6° Fahr. The hair as now clipped short and an ice-cap put on. This seemed to soothe the child. t 4 P. M. the temperature had fallen to 99.6°, and at 9 P. M. a further fall of ° was noted. At midday, after taking some beef-tea, she vomited, and again veral times in the course of the afternoon.

January 9.—Temperature at 1 A. M. 99°, and at 9 A. M. 98°. No vomiting nce yesterday evening. Inclined to sleep. On dressing the wound the charpie as found wet with pus. At 9 P. M., temperature 98.4°, pulse 100. Once sick.

10*th*.—8.30 A. M., temperature 98.4°. Fretful through night, and twice sick. eft pupil perhaps slightly larger than the right. The facial palsy seems not uite so marked. 10.30 P. M., temperature 96°.

11*th*.—4.30 A. M., temperature 96.6°; 11 A. M., temperature 97.6°, pulse 100. rather restless night. Bladder not emptied since yesterday. Several ounces f urine withdrawn with catheter. 6 P. M., drowsy; temperature 97°.

12*th*.—She moves her left arm better. Temperature at 5 A. M., 98°; at 10.30 . M., 96.4°, pulse 78; at 7.30 P. M., temperature 97.4°. Has voided urine.

In the afternoon hungry; asked for and ate with relish a slice of bread-and-butter.

13*th*.—A small hernial button projects through the opening in the bone.

It would be wearisome, and it is not necessary, to continue reading the daily reports from this date. The hernia rose above the level of the scalp, and attained the size of a small nut. It then shrank and disappeared. On the 18th the facial palsy was gone; she was sitting up in bed, playing with toys and prattling merrily at the midday visit. The temperature, however, was still subnormal—it ranged between 98° and 97°, and averaged 97.3°—the normal, 98.5°, not being attained until the 26th. At this date the wound was clean and granulating, and had contracted to about one-half. The left arm was still very feeble; it was colder than the right, and its surface, including the hand, was bluish and mottled; its circulation was manifestly weak.

February 9.—Slight contraction of the fingers of the left hand has occurred; the palsy and feebleness of circulation in the limb continue little changed.

26*th*.—The mottling of surface and coldness of the limb are less marked, the grasp is also stronger, and the palsy of the leg has disappeared.

On March 10 and 27 two small exfoliations came away. After this the wound quickly closed, and on May 10 the scar appeared thoroughly sound; it was, however, thin, and pulsated very perceptibly. She may now be considered convalescent. Every trace of palsy is gone. But, knowing her to have an unhappy home, she is detained still, in order to keep her under observation.

I have given the details of this case at some length because of its importance. The points to which I would particularly ask your attention are, the duty of thoroughly examining every fresh head-injury, the nature of the wound, the date when cerebral symptoms were first noticed, the one-sidedness of the symptoms, the nature of the intracranial disorder denoted by the latter, the value of a true recognition of the association of these symptoms with abscess, the increase of the palsy immediately after the operation, the initial rise of temperature, the fall of temperature on using the ice-cap, the long-continued subnormal temperature, and the hernia cerebri. It will be convenient to take these *seriatim*.

The importance of examining every head-wound when first seen. Had this been done, the fracture—since it was compound, and not a mere crack without irregularity of surface—could not have been overlooked. The omission is very pardonable, for the child was not brought to the surgery till the third morning after the accident, and the absence of symptoms misled. There was not anything in the child's condition to arouse suspicion of a grave injury, and the wound was therefore supposed to involve the scalp only.

The nature of the injury. A punctured wound. Such wounds are, as is well known, often complicated with the impaction of splinters and foreign substances, and are on this account more dangerous than other forms of wounds. (I have mentioned that the mother's account of the way in which the injury was received appeared improbable. An anonymous letter afterwards received, purporting to be written by a neighbour, said that the child's drunken father in a passion threw a small poker at it, and that this stuck in her head.) A wound of this kind ought, therefore, always to be very carefully explored, in order that any splinters, etc., driven through the membranes into the brain may be extracted before the onset of inflammation, since their extraction may avert this.

The late date at which the symptoms of grave encephalic disorder manifested themselves. Eleven days passed between the date of the wound and the fit. Such late appearance of symptoms of grave cerebral disturbance is by no means unusual even in compound fractures of the skull, whilst it is the rule in simple

fractures and in severe bruises with or without external wound, when the encephalic disorder is localized and not diffuse.

Very early in professional life I was taught this by two cases of compound fracture of the vault of the skull by a glancing rifle-bullet, which came under my observation in the Crimean campaign. In one of these cases the parietal bone was shattered and driven in upon the superior longitudinal sinus and brain in which an abscess formed under the fracture. Yet here no grave symptoms were present till after the sloughs had fallen and the wounds had nearly closed. Both men, who had been supposed to have only scalp-wounds, were meanwhile up and about. A woman some years ago admitted into Bird ward furnished an apt example of this late development of symptoms of cerebral disorder. She had been struck in a fray with a brickbat on the right temple, thought little of the cut, drank hard, and went about as usual until a month afterwards, when she fell unconscious, and had convulsions restricted to the left limbs. In the anterior lobe of the right cerebral hemisphere was a large abscess, which was evacuated by trephining.

The kind of symptoms. One-sided spasm and palsy; hemiplegia supervening, not directly, but after an interval, has been thought to be pathognomonic of diffuse inflammation of arachnoid. In the case of our little child, and also in the other cases to which I have just referred, one-sided spasm and palsy, appearing late, were associated with localized and not diffuse inflammation, with cerebral abscess and not diffuse meningitis; and I think this is the rule.

The importance of recognizing the association of intracranial abscess with late cerebral symptoms is evident, since trephining may evacuate an abscess and save the patient's life, whilst in diffuse meningitis trephining is useless.

The increase of the palsy after the operation makes it probable that the hemiplegia was not the direct consequence of pressure (which, in presence of an opening freely communicating with the external surface, could not have been great), but to inhibition of function through nutritional disturbance of brain-tissue around the inflammatory focus, a temporary increase of the local inflammation being provoked by the fresh injury unavoidably inflicted in trephining. The rise of temperature some hours later is favourable to this construction.

The fall of temperature upon the use of the ice-cap. I cannot too strongly impress on you the value of this way of applying cold to the head. I have the strong conviction that I have seen patients with fractures of the skull recover, who but for it would most probably have perished from consecutive intracranial inflammation.

The subnormal temperature observed, lasting during several days, is not unusual in these cases. It occurred also in a case of cerebral abscess successfully trephined in a boy in Percy ward two years ago.

The hernia. Probably this consisted mainly of granulation-tissue and inflammatory products. It was in the main a false hernia cerebri, with little admixture of brain-tissue. No pressure was made on it, and no escharotics were applied to it. It appeared to be maintained by the irritation of the necrosed bone, and to subside on the exfoliation of this.

The child appears to be now quite well, but can we confidently expect she will continue so? May no ulterior consequences ensue? We cannot affirm this. On the contrary, epilepsy not infrequently attacks the subjects of such injuries months afterwards, when they seem to have thoroughly recovered and to be in perfect health.

At the date of publication she continues perfectly well.—*Med. Times and Gaz.*, April 23, 1881.

Hospital Notes.

Atony of the Bladder; Recovery.

J. L., labourer, aged 57, with marked arcus senilis, was admitted into Mr. PEARCE GOULD'S ward at the Westminster Hospital, on August 10, 1880, suffering from retention of urine. He had always enjoyed good health until twelve months before, when he found difficulty in passing his urine. This gradually increased until the night before admission, when after a hard day's work he was unable to pass a drop. The "difficulty" he noticed was a slow, feeble stream, and inability to empty his bladder, with frequency of call to micturate.

On admission the distended bladder formed a prominent tumour in the hypogastrium, reaching almost up to the umbilicus. The prostate felt from the rectum was hard and moderately enlarged. Mr. Gould passed without any difficulty an olive-headed catheter, No. 10, English scale, and drew off rather more than four pints of clear, acid, healthy-looking urine. The urine flowed slowly, falling vertically from the end of the catheter. The influence of respiration on the stream was evident. After the escape of about a pint the flow ceased, and the rest was forced out by the hand above the pubes, and when the pressure was relaxed air was heard to be sucked in through the catheter. The man was kept in bed on full diet, and his bladder was emptied by catheter night and morning. On Aug. 15 a mixture containing five minims of tincture of nux vomica was ordered to be given three times a day. The catheter was always carefully washed in carbolic lotion—5 per cent.—before being used, and lubricated with carbolic oil—10 per cent. This appeared to cause some irritation of the meatus, and vaseline was substituted for the oil, and the irritation quickly passed away. There was no sign of any vesical irritation; the urine remained clear, acid, free from mucus and albumen, and the bladder gradually regained its expulsive power. Thus on Aug. 15, the patient could pass 4 oz. of urine by his own efforts, and on Aug. 17 this had increased to 10 oz., and thus he improved until on his discharge on Sept. 15, there was only half an ounce of "residual urine" to be drawn off.

Remarks.—This case is an example of the extreme degree of atony of the bladder with complete retention of the urine, not unfrequently met with in connection with chronic prostatic enlargement. The daily use of the catheter has long been recognized as the proper mode of treatment for such a condition, but the occurrence of decomposition of the urine with subsequent chronic cystitis have too often prevented the attainment of a perfect result. The case illustrates one application of antiseptic surgery to urinary surgery, and its value in preventing the decomposition of the urine can hardly be overrated. The result of the daily emptying of the bladder in leading to a gradual and almost perfect recovery of the bladder's power, throws considerable light on the way in which this atony of the bladder is originally produced. For it is clear that it is not by obstruction to the outflow of urine with retention and stretching of the muscular coat of the bladder, nor is it from any local action of decomposed urine; but rather, it seems from a small primary "residue" of urine. A few drachms which the bladder cannot evacuate have a paralyzing influence upon the bladder muscle, which leads to the retention of a greater amount of urine; this, again, to further diminution of expulsive power, and so on until the stage of complete retention and atony is reached. The history of such cases before they come under treatment, as well as the results of catheterism, bear out this view. The symptoms often arising from a very small quantity of "residual urine" and the importance of its relief have been laid stress upon by Sir H. Thompson. The patient's condition (March 1) remains as on the date of his discharge; he continues to draw off the few drachms of "residual urine" every night. The quantity has not increased since he left the hospital.—*Lancet*, March 12, 1881.

MONTHLY ABSTRACT.

Anatomy and Physiology.

A Case of Movable Liver.

In the *Wiener Med. Blätt.* is recorded an observation accidentally made on a ysician by Dr. CHVOSTEK. There were no symptoms whatever of anything ong in the abdomen, and there was no history of violence or of any occur- nce that threw light upon the condition. When the man stood up, the upper d posterior border of the liver was felt to come forward from under the margin the thorax, and to be six centimetres and a half below the tip of the xiphoid rtilage in the right parasternal line, and one centimetre below that point in the t parasternal line. The left end of the liver was plainly felt through the dominal wall, and from it the anterior, or rather the lower edge of the liver uld be traced arching down to the right, being in the middle line fifteen centi- tres below the xiphoid process, and in the right nipple and axillary lines spectively seven and one-and-a-half to two centimetres below the edge of the orax. The liver did not markedly descend on taking a deep inspiration. In e horizontal posture it could be replaced under the ribs to a considerable extent. lying on one side the organ fell to some extent towards the dependent side. e lower edge of the suspensory ligament could be felt tightly stretched, but this oduced no pain, and so completely absent were all symptoms that the condition s only discovered accidentally.—*Lancet*, March 12, 1881.

The Source of the Liquor Amnii.

Our knowledge concering the source of the liquor amnii is somewhat uncertain, d two theories are held with regard to it. The first is that it is the product of e secretion or transudation from the maternal vessels in the uterus; the other, at it is the product of the secretions of the fœtus. Accurate knowledge upon s subject is of very great importance, for its elucidation lies at the foundation the pathology of some of the diseases of pregnancy and intra-uterine life, and volves the whole question of the activity of the kidneys in the fœtal state. xperiments have been made upon pregnant animals with a view to solving the oblem, and the most recent are those conducted by WIENER in Breslau, the sults of which are published in a paper in the *Archiv für Gynäkologie*.

Two or three kinds of experiments have been performed. In the first, a lution of sulph-indigotate of soda was introduced into the jugular vein of rabbits an advanced state of pregnancy, and the animals killed at intervals ranging om a quarter of an hour to two hours and a half after the injection was made. was then found that the liquor amnii in all the cases contained the colouring aterial used, its presence being proved by the microscope. In none of the ses was the colouring material found in the organs of the fœtus, with the ception of the stomach and intestines, into which it had obtained admission by e process of swallowing; none appeared to have passed by the fœtal kidneys. he quantity of the material found in the liquor amnii was small, and this peared to be due to its elimination by the maternal kidneys. To obviate this e kidneys were extirpated before the injection was made, and in cases thus eated a large quantity of it passed into the amniotic fluid. When animals in

the early stage of pregnancy were similarly treated, hardly a trace of colourin matter was found in the liquor amnii. To decide what part the fœtus plays i the production of the liquor amnii, the colouring material was introduced int the body of the fœtus. A quantity of the coloured solution was injected into th amniotic sac and the fœtus made to swallow, but it was found that the materi did not in this way enter the blood of the fœtus. It was then injected under th skin of the back of the fœtus. On subsequent examination, the colouring mat rial was found in the kidneys of the fœtus in precisely the same situation as was found in those of the mothers in the first series of experiments. It w traced there as soon as twenty-five minutes after the injection, and in one case drop of coloured urine was discovered in the bladder. In these experiment moreover, the liquor amnii was coloured blue.

From these data Wiener argues that the fœtal kidneys are not only activ during fœtal life, but that they secrete rapidly, and are the chief source of th liquor amnii. He maintains, moreover, that during early life the fluid com exclusively from the embryo until the fœtal membranes come into intimate co tact with the maternal tissues, and the placenta is formed. At first the fluid derived from the cutaneous vessels of the fœtus, afterwards from the Wolffia body, and later from the kidneys. After the membranes have come into intima connection with the uterus, a portion of the fluid comes from the maternal vessel Wiener explains the varying results of chemical analysis of the liquor amni and the occasional absence of urea in it, by the statement that the urea in it co tinuously undergoes decomposition or diffusion into the maternal blood.

Besides the experiments referred to, other evidence bearing upon the questio is brought forward and discussed, especially that furnished by cases in whic occlusion of the urinary passages had occurred during fœtal life. In these cas considerable quantities of urine have been found behind the occlusion, the secr tion of which, according to Fehling, is pathological. This opinion of Fehli is, in our opinion, successfully controverted by Wiener. It cannot be questione after the evidence brought forward, that both the maternal vessels of the uter and the secreting organs of the fœtus contribute to the production of the amnioti fluid, but the proportion the contributions of each bear to one another cannot b regarded as finally settled. The evidence adduced by Wiener in favour of th fœtal kidneys being the chief source, although indirect in its characters, goes fi to prove his view; but until further and more conclusive evidence is adduced w cannot go beyond the statement that the liquor amnii is the joint product of th vessels of the uterus and of the fœtal kidneys.—*Lancet*, March 12, 1881.

Materia Medica and Therapeutics.

Chaulmugra Oil.

Chaulmugra oil is obtained from the seeds of *Gynocardia odorata*, a lar tree, much branched, with ash-gray globular fruit, some three or four inches diameter. It is a native of Pegu, Tenasserim, and other parts of the Malay peninsula, whence it extends into India, being found in Assam, Khasia, and Si kim, but not in the central or western parts. The seeds (*Gynocardiæ semin* are officinal in the *Indian Pharmacopœia*, and are popularly known as chaulm gra, chaulmogra, or chaulmoogra seeds. The oil expressed from these seeds h been known for centuries to the Fakirs of India, by whom it is largely used in t treatment of leprosy, and skin diseases generally. There is evidence to sho

hat it has been employed by the aboriginal tribes in certain parts of India from he remotest times.

At the ordinary temperature, the oil is solid, has a light-brown colour, and a ecidedly disagreeable taste and smell. It may be readily melted by placing the ottle in hot water, or allowing it to stand for a few minutes in front of the re. It has been analyzed, and is found to consist of palmitic, gynocardic, hypoæic, and coccinic acids. The palmitic constitutes sixty-three per cent.; but the ynocardic acid, which is found in a much smaller proportion, is probably the ctive ingredient. The oil is given internally, and is also used as an external pplication. It is most conveniently administered in empty capsules, or in *perles;* ut many patients take it well in milk, cod-liver oil, or almond-oil. The usual ose is from five to fifteen minims. It is best to begin with a small dose, say two three minims, three or four times a day, gradually increasing the quantity as e patient becomes accustomed to it. Dr. Murrell, as the result of a large umber of observations, found that, when administered in milk or cod-liver oil, n minims very frequently upset the stomach, giving rise to nausea and vomiting, nd not unfrequently diarrhœa. The chaulmugra oil *perles* contain four minims ch, and most patients will take from one to four of these at a dose. When it desirable to vary the dose frequently, the empty gelatine-capsules will be found eful. It is almost essential that some such special mode of administration ould be adopted, as few patients like the taste of the oil, or will consent to ke it by itself for any length of time. It must always be given after meals.

Chaulmugra oil has long been used in India in the treatment of leprosy, and s acquired a high reputation as a remedy for that disease. From the comrative rarity of true leprosy in England, much difficulty has been experienced collecting a sufficient number of cases in which to try its effects. This difficulty increased by the fact that, in temperate climates, the disease often exhibits ng periods of comparative rest or subsidence, quite apart from any special treatent. Dr. Robert Liveing has published a record of six cases of elephantiasis ræcorum, in which he was able to give the chaulmugra a long and continuous ial. He found that all six cases were decidedly benefited by the treatment, nd the patients themselves were strongly impressed with the belief that they nd decidedly improved under its internal use as a medicine. Mr. Wyndham ottle has also published two cases in which equally good results were obtained. he oil was here given either as a mixture suspended in gum, or in the form of nulsion. Unusually large quantities were administered, the dose being gradually creased to as much as a drachm three times a day. Moreover, an ointment, nsisting of twenty grains of chaulmugra oil to the ounce of lard, was applied ely to the skin. Quite recently, Dr. David Young of Florence has published more extensive series of cases in which most striking results were obtained. he forms of the disease noted were: macular leprosy, four; anæsthetic leprosy, enty-three; tubercular leprosy, fifteen; and mixed cases, eleven. The paents were all adults, the proportion of males to females being about three to e. The treatment consisted in the internal administration of doses varying om five to twenty drops, three times a day, commencing with the smaller uantity, and gradually increasing it until the latter was reached. Externally, a iiment, composed of an ounce of the oil, mixed with a drachm of rectified irit, was applied to the diseased surface. Dr. Young found that, in the macular nd in the early stage of the anæsthetic forms of leprosy, the chaulmugra was of ecided value. The good results appeared earlier when the powdered seeds ere given in addition to the oil. A liberal milk-diet was found to be a aluable auxiliary. Several of the cases were complicated with bronchial affec-

tions, which were markedly benefited during the treatment, all the patients gaining flesh rapidly.

In many skin diseases, the chaulmugra oil treatment proves beneficial. It has been tried with success in psoriasis, lupus, and obstinate cases of scabies and ringworm.

Chaulmugra oil was originally introduced as "a specific for consumption;" but there is certainly as yet no evidence to show that it deserves this distinctive title. Dr. Burney Yeo has reported nine cases of phthisis in which it was given internally with little or no benefit. He considers that it gives no promise of help in well marked cases where the disease has reached the stage of infiltration and softening of any considerable portion of the lung. Dr. Murrell, as the result of a series of observations extending over two years and a half, arrives at a somewhat different conclusion. In thirty-one of his cases, the chaulmugra oil was given in milk, in doses ranging from three to ten minims, four times a day; and in twenty-four of these, decided benefit was experienced. The chaulmugra seemed to act, first, as an expectorant; then the cough became less troublesome and, finally, a gradual improvement took place in the general symptoms. The best results were obtained when, in addition to the internal administration, from two to four ounces were rubbed into the chest weekly for two or three months. The inunction never upsets the stomach or gives rise to unpleasant symptoms. The smell is not very agreeable, but is readily covered by using a little violet powder. The oil may be employed alone or simply as an adjunct to other treatment.

It is found that children, as a rule, take the chaulmugra without difficulty; and its internal administration, combined with inunction, has been employed with benefit in scrofula and in cases of marasmus.

In chronic rheumatism and in rheumatic gout, it is most useful. A patient recording his own experience, says: "A month since, I was suddenly seized with a severe attack of rheumatism; and so acute was the pain, that, for two days and nights, I could not sleep, and the swelling of my hands made me quite helpless. I could neither dress nor feed myself. Having had a sharp attack of rheumatic fever about twenty years ago, I was very much afraid that I was again to be laid aside from business; and you, I fear, will hardly believe that, within three hours of the application of the oil, the use of my hands was restored to me; and that, from that day to this, I have had no return of the pain." Non-professional testimony is not, as a rule, very trustworthy, but there are occasions when it cannot be ignored. For stiff joints, sprains, and bruises, both in men and horses, the oil is said to be equally efficacious.

For neuralgia and sciatica, the chaulmugra oil is generally mixed with camphor and chloroform, or with an equal weight of a saturated solution of menthol in chloroform, and then rubbed in over the painful part.—*British Med. Journal*, March 26, 1881.

Therapeutic Use of Pilocarpin.

That jaborandi, or, rather, its alkaloids, are likely to come into more general use as powerful therapeutic agents, appears to be indicated by the numerous notices of their employment which have recently appeared in the periodical literature of Europe and America. Within the last year, the use of pilocarpin has been advocated by more than one writer—notably, by Dr. Berkart—and it may therefore, be of some service to our readers to consider certain of the facts in regard to its action which have been recently brought to light.

In August last, HARNACK and MEYER published (*Arch. für Exper. Path.*

e., vol. xii. p. 366) the results of observations which they had made in Pro-
ssor Schmiedeberg's laboratory in Strassburg on jaborandi and its alkaloids.
hey found that the jaborandi leaves contained not only the alkaloid pilocarpin,
ıt also another similar body, which they named jaborin, which was, to a great
xtent, antagonistic to pilocarpin in its action. This second alkaloid they found
be present in all ordinary specimens of pilocarpin; and to the presence of this
dulteration they ascribed the somewhat contradictory results obtained by former
servers. The pure pilocarpin causes, in warm-blooded animals, at first irrita-
on of the terminations of the vagus in the heart, and, indirectly, of the vaso-
otor centres; and, later, and in larger doses, paralysis of these terminations
d centres. In spite of the paralysis of the vagus, the pulse becomes slower
d slower. In regard to its action on the heart and bloodvessels, it closely
sembles nicotin. Pre-eminently may pilocarpin be characterized as a drug
hich causes increased glandular secretion. It acts most energetically upon the
livary, sweat, mucous, and lachrymal glands; and that this increased secretion
not caused by the vaso-motor paralysis, of which we have spoken, is shown by
e fact that that paralysis comes much later than the outpouring of the secre-
on, which is the first symptom of the action of pilocarpin. This result is prob-
ly due to an irritation of the nervous apparatus governing the gland. To the
her actions of pilocarpin—on the pupil, the intestine, the uterus, etc.—we need
t here refer.

The greatest value of pilocarpin appears to consist in its power of causing rapid
mination of effete material in cases of scarlatinal nephritis. It has been fre-
ently administered in such cases, and with much benefit; and it appears likely
at, if it be given with proper precaution, and with a due appreciation of certain
ngers which surround its use, it may frequently be the means of saving life.
hat these dangers are has been lately very carefully pointed out by Dr. See-
nn of Berlin (*Zeitsch. für Klin. Med.*, 1881, vol. ii. p. 552), and they de-
nd the consideration of every intelligent physician. That œdema and urœmic
enomena, in cases of scarlatinal nephritis, are neither proportionate to one
other nor to the quantity of urine passed, can readily be observed. In some
stances, urœmia occurs when a normal quantity of urine is excreted, while in
hers no urœmic symptoms follow several days of anuria. In the former cases,
e urine contains little urea, and in the latter the urea passes from the blood
to the œdemic fluid, and hence becomes harmless for the time. When, how-
er, at the beginning of convalescence, the excrementitious materials pass back
to the blood, urœmia may come on; and obviously, the more rapidly they pass
ck the more danger is there. In virtue of its power of producing prompt and
ergetic increase of the sweat, salivary, and other glandular secretions, pilo-
rpin causes a very rapid reabsorption of the transudation, and, therefore, its
ministration may give rise to urœmic phenomena, which, though transient,
ay be highly dangerous. Seemann instances one case, in which this untoward
sult followed the administration of pilocarpin. Ohms (*Petersburg Med.
Voch.*, 1878, No. 6), as well as Seemann, has observed that pilocarpin may
use, not merely dilatation of the small arteries, but even rupture of these ves-
ls, and consequent hemorrhage; and if we recollect that the child affected with
arlatinal nephritis lies on his back, too weak to cough up the rapidly augment-
g mucus which the pilocarpin calls forth, it will be seen that the circumstances
the case may predispose to catarrhal pneumonia to a dangerous degree. See-
ann gives the following indications for the use of pilocarpin in such cases of
ephritis:—

"1. Muriate of pilocarpin is useful in cases of scarlatinal nephritis, and may
ften save life when other remedies fail; but it must not be resorted to except

in very serious cases. 2. When, after its successful administration, the œdema begins to lessen, cure should be left to nature and to other remedies, because renewed doses of pilocarpin may cause too rapid absorption of the transudation, and may thus lead to uræmia. 3. After each dose of pilocarpin, the state of the respiratory organs must be carefully watched; if the bronchial mucus be not satisfactorily expectorated, or if the slightest indication of pneumonia show itself, further doses of the drug must not be given."

We believe that, if such indications be borne in mind, pilocarpin may be used safely and with great success in cases of scarlatinal nephritis which are otherwise hopeless; but the preparation used must be obtained from a thoroughly trustworthy source, and must be free from the jaborin which most specimens are said to contain, and which materially modifies the action of the drug.—*London Med. Record*, March 15, 1881.

Medicine.

Pathology of Atheroma.

The theory of the origin of atheroma, to which Virchow has given currency, regards it as of inflammatory origin, and has been conveyed into modern pathology by the help of the name "endarteritis deformans." This designation, although not unassailable, has been widely accepted on account of the apt expression which it gives to the conspicuous characters of the morbid change. The same theory of initial inflammation has been, in effect, adopted by Lancereaux, while Cornil and Ranvier do not admit any other element in the morbid process than simple degeneration.

The latter view is regarded as the more probable by the writer of a recent memoir in the Paris *Revue de Médicine*, M. HIPPOLYTE MARTIN, who has endeavoured to ascertain the pathological origin of the degeneration, and believes that he has found it in a lesion of the nutritive arteries of the walls of the vessels, to which the visible degeneration is simply secondary. In the early stage of the affection the cells of the connective tissue of the vessels may be found notably increased in number, and the middle and internal coats are increased in thickness; these changes cannot be regarded as the result of any irritation by the globules of fat which may be found sparsely scattered through the wall. If the minute vessels which ramify in the external coat before penetrating the middle layer are examined, they are found to be healthy, with the exception of those which correspond to the spot of atheroma. Here, however, the nutritive artery of the degenerated region presents a striking proliferative endarteritis, which, in the case of extreme degeneration of the atheromatous patch, amounts to almost complete obliteration of the minute vessel, so that very little blood can circulate through it. This lesion is never absent, although considerable care may be necessary to find it. The change is only found in the vessel going to the diseased spot; other arteries, although closely adjacent, may be perfectly healthy. But it may be held that in the old, in whom generalized arterial disease is common, the affections of the arteries and of the nutritive vessels may be due to the same cause, and do not stand in any causal relation. In contravention of this objection M. Martin describes the case of a lad, nine years of age, who died of diphtheria. At the autopsy two atheromatous spots were found in the commencement of the aorta, above the sigmoid valves. They were well marked, about a square centimetre in extent. All the other vessels were healthy. Sections at the position of the atheromatous patches showed, in the middle of healthy tissue of the outer

and even of the middle coat, a perfect example of endarteritis of the nutritive vessels, one of which was almost obliterated. Moreover, it was evident from the histological characters of the two that the affection of the nutritive artery was of older date than that of the inner coat of the aorta.

This lesion in the vasa vasorum appears to commence in their inner coat, the nutritive supply to which is always the most difficult, but at a later stage the middle coat is also affected, and its muscular fibres may be observed to undergo a fatty degeneration. This alteration is regarded as inflammatory in nature, the result of some, at present unknown, cause. The facts Martin has ascertained are of much interest and importance, but they only put the origin of the disease farther back, and farther into the region of pathological mystery. It is conceivable that mechanical strain and other causes may determine the occurrence of a degenerative inflammation beginning in the wall of the strained vessel, but the cause of the affection of the vasa vasorum is entirely unknown. The changes in the larger artery may be due to the disease of the minute vessels, but what is to explain the latter lesion? And if we admit it to be a primary endarteritis, may not the disease of the wall of the larger vessel be in many instances of the same nature?—*Lancet*, March 26, 1881.

—

Inoculation with Hydrophobic and other Saliva.

Prof. PASTEUR some time since announced to the Academy of Medicine that, in the blood of some rabbits which he had rapidly killed by inoculating them with some of the virus from a child suffering from hydrophobia, he had found a new *microbe*, which he evidently regarded as the microscopic being to which were due the specific properties of the hydrophobic virus. As in several other of his discoveries, his conclusion seems to have been a somewhat hasty one, for in a subsequent communication to the Academy (*L'Union Méd.*, March 24) he announces that in same experiments performed with the saliva of children dying of broncho-pneumonia he had produced exactly the same results. He therefore had to abandon his supposition that the *microbe* in question was specially connected with rabies; but, far from regarding this result as unfavourable to his doctrine as to the parasitic origin of virulent diseases, he considers that the detection of the *microbe* in the saliva of children dying from ordinary diseases opens up a new horizon to the doctrine of the parasitic origin of diseases, removing it from the restricted circle within which it has hitherto been confined, to the wider field of general pathology.

Prof. VULPIAN has recently addressed a note to the Académie de Médecine (*L'Union Méd.*, March 31), stating that he had injected under the skin of some rabbits saliva collected at the moment from persons in perfectly good health, and that the injection caused the death of the rabbits within forty-eight hours. Their blood was found filled with *microbes*, including the special one found by Prof. Pasteur after inoculating with the saliva taken from a hydrophobic patient. A drop of this blood diluted in ten grammes of distilled water, and injected under the skin of other rabbits, caused likewise the deaths of these animals, their blood also being found filled with *microbes*. These singular results, the interpretation of which is not very easy, are accompanied by another no less singular in not being constant. Other rabbits placed under identical conditions, and inoculated with the same saliva, did not experience the slightest inconvenience. It would certainly seem that experimental microbiology is scarcely yet on the way of becoming a clear or easy science in spite of the *fiat lux* of Prof. Pasteur.—*Med. Times and Gazette*, April 2 and 16, 1881.

Arsenic in Pseudoleukæmia.

Dr. F. W. WARFVINGE relates in *Hygeia* for 1880 (*Nord. Med. Arkiv*, Band xii. Häft 4) four cases of pseudoleukæmia, principally with the object of showing that treatment by arsenic has a decidedly favourable effect. The first patient, a man aged 56, had enlarged lymphatic glands in the neck, groins, and axillæ, varying in size from a walnut to a hazel-nut; splenic dulness was 11 centimetres (4.3 inches) long by 10 centimetres (4 inches) wide. There were 3,220,000 red blood-corpuscles in a cubic millimetre; the white corpuscles were in the proportion of 1 to 140 red. Solution of arsenite of potash was given in two-drop doses twice daily; it was not tolerated at first, but, after a catarrh of the digestive and respiratory organs had disappeared, it was again taken without any inconvenience. Under the use of this medicine, a marked improvement showed itself; the lymphatic glands and the spleen diminished, and, after the arsenic had been taken (always in the dose above mentioned) for five weeks, the spleen had regained its normal size, and only slight traces of the enlargement of the glands remained. After apparent recovery, the disease returned, and the patient died a month afterwards. The second patient was a woman aged 62, with enormous lymphatic swellings in the neck, groins, and axillæ, and splenic dulness 9 centimetres in breadth. There were 3,700,000 red corpuscles in a cubic centimetre, and 1 white to 450 red. Four drops of liquor arsenicalis were given twice daily, and injections of arsenic (first 4, afterwards 9 drops a day) were made into one or other of the axillary glands. After twenty-five injections, the mass of glands was reduced from the size of a fist to a mass one inch in diameter. The patient died in an attack of asphyxia. At the necropsy, many lymphatic glands, varying in size from a hazel-nut to a walnut, were found in the anterior mediastinum. The cervical and retroperitoneal glands were swollen; the spleen was 15 centimetres long and 9 centimetres broad. The ribs and sternum were very brittle; a gray-red mass escaped from the broken surfaces. The marrow of the femora presented the same appearance. In the third case, a woman aged 27 had a mass of enlarged glands, varying in size from a walnut to a hazel-nut, lying on the left side of the neck, and extending from the angle of the lower jaw into the subclavicular and axillary regions. In the groins and axillæ the swellings were somewhat smaller. There was nothing abnormal in the internal organs. The number of red corpuscles in a cubic millimetre was 3,700,000; and there was 1 white corpuscle to 250 red. Under the use of arsenic, reduction in the size of the lymphatic glands proceeded slowly but steadily, so that their size was considerably diminished. The fourth case was that of a boy, aged 8, with considerable enlargement of the cervical, axillary, and inguinal glands. The internal organs were healthy. There were 4,370,000 red blood-corpuscles in a cubic millimetre and 1 white corpuscle to 190 red. Four drops of liquor arsenicalis were given twice daily, from July 18th to December 17th, with two short intervals. The lymphatic swellings diminished gradually, and the patient's appearance became more healthy.—*London Med. Record*, March 15, 1881.

Pathology of Diphtheria.

The pathological relations of diphtheria and the discovery of a micrococcal organism in the false membrane have made it almost certain that the morbific poison which gives rise to the disease is a parasitic organism. The observations to which we lately called attention that bacilli were to be found during life in the urine of patients suffering from the disease, and after death in the kidneys, con

stitute another step in the demonstration. From a communication to the Paris Société Anatomique we learn that a French "interne," M. TALAMON, has succeeded in cultivating the organisms from eight cases. In the condition of complete development they presented a characteristic mycelium and spores. The former are tubes with partitions, at intervals, from two to five thousandths of a millimetre in length. These, under favourable circumstances, elongate and bifurcate, the bifurcations being characteristic in consequence of their incurved branches, like the sides of a lyre. In other conditions the mycelia do not become elongated, although they multiply so as rapidly to cover the surface of the cultivation liquid; they remain short and assume irregular forms, and give rise to numerous straight rods.

The spores are of two kinds, round or oval, which may be termed the spores of germination, and rectangular spores or conidia. The latter characterize the species. They form small rectangles of various sizes, their length being sometimes fifteen thousandths of a millimetre. They may be isolated or united in festoons or zigzag chains. At first homogeneous, they soon become filled with small round granules, highly refracting, and of the size of ordinary micrococci. The round or oval spores are those which, by their elongation, constitute the mycelium. They appear as clear points, from three to five thousandths of a millimetre in diameter, in the middle of a mass of granular material.

M. Talamon has inoculated this organism into the mucous membrane of the mouth or nose, or has given it with the food, in six rabbits, two guinea-pigs, four frogs, a fowl, and four pigeons. The rabbits died at the end of six, eight, ten, and eighteen days. That which died soonest presented an enormous swelling of the neck resembling the œdema of the neck in diphtheria, and due to a serous infiltration of the connective tissue, and the culture of this serosity showed the same organism with the characteristic conidia. The rabbit which died at the end of eighteen days presented a bilateral fibrinous pleurisy, with effusion. The effusion and pleuritic membrane also yielded, on culture, the organism which had been inoculated; and it could be recognized, either by simple microscopical examination or by culture, in most cases in the liquid contained in the pericardial and peritoneal cavities, and often in the kidneys. The organism was never obtained by cultivation of the blood contained in the heart. The liquid either remained clear or presented only ordinary bacteria.

In the four pigeons M. Talamon succeeded in producing characteristic false membranes. He first scratched the mucous membrane of the mouth with a bistoury, and then placed some of the cultivated organism in the interior of the mouth. At the end of twenty-four hours a thick membrane lined both sides of the mouth, the tongue, the false palate, and the back of the pharynx. It was yellowish-white in colour, and was formed, like the diphtheritic membrane in man, by epithelial cells, fat, micrococci, and bacteria. There were very few of the rectangular conidia, but these were abundantly obtained from the membrane by cultivation. Two of the pigeons died at the end of three days. In one the entrance to the larynx was covered by false membranes, and the trachea was full of a thick mucus from which the organism was obtained by cultivation, as also from the pericardial and peritoneal liquids, but not from the blood. The third pigeon remained ill for eight days, and then the false membranes became separated and the animal recovered. At this point, unfortunately, the experiments have been for the present arrested. They were carried on in the laboratory of the Hôtel Dieu, and some of the physicians, fearing lest some of the organisms might contaminate the patients, stopped the observations. We are promised a resumption of the inquiry at an early period. The facts ascertained are of the greatest importance, and seem to open out an entirely new field of investigation

as to the etiology of the disease, since M. Talamon hints that he possesses a clue as to the source from which the organism is derived in the case of human infection.—*Lancet*, April 9, 1881.

—

Treatment of Diphtheria with Muriate of Pilocarpin.

LAX (*Aertz. Intel. Blatt.* 1881, No. 43), following Guttmann, has employed muriate of pilocarpin in a small epidemic of diphtheria, and has obtained results so far beyond his most favourable anticipation, that he thinks himself obliged to recommend it most earnestly for wider use. Between September 24 and November 17, he treated for diphtheria sixteen children of various ages, from one to sixteen years. The first six children were treated by pencilling with a four per cent. solution of nitrate of silver, and a solution of chlorate of potash as a gargle. To two quite young children, a mixture of chlorate of potash was given. Of the six children, four recovered quickly, while two, whose cases were very severe, died. In the last ten cases occurring after October 5, Lax employed exclusively the muriate of pilocarpin. Six of these were very severe, and in two of them death was expected every night. Nevertheless, all these children treated with pilocarpin entirely recovered. An increased secretion of mucus and saliva occurred, and great masses of diphtheritic effusion were expelled from the mouth as well as the nose. The breathing became freer, *râles* ceased to be heard, the fever passed away, and the appetite recovered. The children generally recovered in from three to five days. Labial herpes indicated the favourable processes in all cases. On the third day already all trace of the deposit on the soft palate and tonsils was removed. According to the age, Lax prescribed two to four centigrammes of muriate of pilocarpin, 60 to 80 centigrammes of pepsin, with two to three drops of hydrochloric acid in 70 grammes distilled water, giving every hour from one teaspoonful to one tablespoonful. In addition, Tokay wine was given hourly (a teaspoonful to a tablespoonful), and warm packs were applied to the neck.—*London Med. Record*, March 15, 1881.

—

Diabetes associated with Disease of the Pancreas.

In 1877 M. LANCEREAUX read a note at the Académie, in which he demonstrated the existence of a form of diabetes mellitus, found in conjunction with pancreatic lesions. This, he alleged, constituted a special and distinctive variety of diabetes, characterized by a *début brusque*, considerable emaciation, with polydipsia and polyphagia, by peculiar alvine evacuations, and especially by a very rapid evolution. The study of Lancereaux has been made the basis of further investigations by M. DEPIERRE (*Jour. de Méd. et de Chir. Pratiques*, Dec. 1880), which have led to the discovery of new facts in this connection. Various kinds of pancreatic alterations may be regarded as leading to this kind of diabetes. They may be primary lesions, or they may be the secondary result of the presence of calculi, or else they may be caused by compression of the ducts by neoplasms. In all such cases, there appeared to be a complete abolition of the pancreatic function. This suppression of a digestive function is revealed by special symptoms, thus constituting a variety of diabetes (called by the author "emaciating diabetes") which differs greatly in its clinical aspects from ordinary polyuria. In the latter disease there is said to be, as a rule, an initial stage of obesity, or at least of apparent health, thus rendering the progress of the malady slow and insidious. In pancreatic diabetes, on the other hand, we notice along with the absence of *embonpoint* a quite sudden explosion of symptoms. These ordinarily consist of grave intestinal manifestations, vertigo, vomiting, and jaundice. These symptoms after a while indeed disappear, but they leave the patients in a

condition of profound debility. Soon the essential symptoms of the disease put in their appearance. Sometimes, indeed, they occur from the very beginning, without any previous indications of morbid changes. They are polydipsia, polyphagia, polyuria, and autophagia (the latter probably meaning tissue-waste and emaciation). This combination of symptoms is rapidly established, reaching an acme in a few weeks or months, and it is this very point which appears to afford pathognomonic indication of the existence of this variety of diabetes. The habitual presence of diarrhœa is also noted. Sugar is voided in great abundance with the urine. Pulmonary phthisis is also a frequent complication. Emaciation is rapid. In a few months the patients lose successively their physical, intellectual, and genital powers. Then complete prostration and profound marasmus set in, to which there is superadded hectic fever, with the symptoms of consumption. The average duration of the sickness is about twenty months, though it may end in half a year, or last even three years. Greasy or creamy stools may afford a clue to the establishment of the diagnosis of pancreatic diabetes, but it must be remembered that they occur also in other affections of that organ. Another point which must be considered is the deficient digestion of nitrogenized substances in atrophic conditions of the pancreas. Thus, pieces of undigested muscle found in the stools of patients may awaken a suspicion of this disease. Besides the ordinary treatment of diabetes mellitus, the administration of pancreatine suggests itself as affording a possibility of artificially supplying the lacking aids to digestion.—*London Med. Record*, April 15, 1881.

—

Medical Ophthalmoscopy.

In the *Berliner Klinische Wochenschrift* (Nos. 1 and 2, 1881) Dr. LITTEN gives an account of certain clinically interesting changes in the fundus of the eye.

1. In *General Anæmia.*—The fundus is bright red; the disk pale and sharply defined, becoming ultimately quite white, but without the bluish tint of atrophy. The arteries and veins are small, the central streak indistinct. Less characteristic, though more striking, are hemorrhages and white or grayish-white spots on the retina. Later the symptoms of neuritis or neuro-retinitis occasionally appear —the radial streaked clouding first of the disk, then of the retina, with the development of a white border to the vessels. Examining such retinæ microscopically, Dr. Litten observes a general cell-infiltration of the retina, and an inflammatory exudation of pus corpuscles ensheathing the vessels, these changes not proceeding in anæmia to the alterations in the interstitial tissue characteristic of chronic retinitis. The neuritis is sharply intra-ocular, and consists in cell infiltration and hypertrophic nerve-fibres. The white patches consist sometimes exclusively of white blood-corpuscles, with occasionally hypertrophic nerve-fibres, but never, he finds, exclusively of the latter. The power of vision is very little affected by the hemorrhages or the white patches unless actually in the central part of the retina. No one of these changes, he finds, is characteristic of particular forms of anæmia. Hemorrhages are in no way characteristic of pernicious anæmia, and, except as showing that the anæmia has reached a high grade, in no way justify an unfavourable prognosis. These hemorrhages and white patches he believes are, in general, of much commoner occurrence than is usually supposed. For example, he has met with them very frequently in cases of carcinoma uteri, more especially in fat, flabby females with cardiac symptoms like those produced in anæmia. Neuritis and neuro-retinitis are, in Dr. Litten's experience, more common after great loss of blood than in chronic anæmia, coming on generally in the first or second week after the loss, and leading frequently to atrophy.

2. In *General Venous Congestion.*—The fundus is here dark or even blackish red, the disk also dark red. The vessels are gorged and tortuous, the tortuositie rising occasionally out of the plane of the fundus. With these differences fro anæmia, there occur the same hemorrhages, white patches, and inflammations the retina and optic nerve. The hemorrhages accompany the veins, and are n unfrequently in the periphery, where they may be readily overlooked. Th white patches are rarer than in anæmia; inflammation, with marked swelling the disk, more common. This inflammation he considers must depend on som other cause than simple anæmia or simple congestion, as he has in numerou experiments produced these conditions without being able to cause inflammatio The above changes he has observed most frequently in the general venous con gestion of chronic bronchitis and emphysema, and in two such cases with marke cyanosis he saw in the periphery peculiar coin-like hemorrhages which we do n remember having seen described. They were of various sizes, with sharply de fined edges, mostly in relation with the veins, hanging on them like berries on stalk. In one of these patients a second and fatal attack showed hemorrhage of the same peculiar character, lying chiefly in the outer retinal layers.

3. *Case of Poisoning with a Mixture of Nitro-benzol and Aniline.*—Th patient was admitted in the deepest coma, which lasted forty-eight hours. Th skin and mucous membranes, in place of the usual blue or grayish-blue of pur nitro-benzol poisoning, had a deep violet colour. The fundus was of an intens violet colour, with a few slight hemorrhages, the vessels as if filled with ink There was no affection of sight, either as to sharpness or perception of colou Whether the blue colour in pure nitro-benzol poisoning result from reduction the nitro-benzol to aniline, or, as seems more probable, from deficient absorptio of oxygen, there appears good reason to suppose that the violet colour in this ca resulted from the aniline mixed with the nitro-benzol.

4. *Apoplexy of the Brain and Retina from miliary aneurisms.*—The patie was struck down suddenly with left hemiplegia and the usual partial faci paralysis of the same side. The ophthalmoscope showed numerous and extensiv hemorrhages, completely hiding the fundus. The post-mortem examination di closed numerous subarachnoid and intra-cerebral hemorrhages, with aneurism dilatations of the vertebral and middle cerebral arteries. The retina was su pected to be similarly affected, and on examination was found to be so, but owin to the diseased vessels lying everywhere amid the hemorrhages, no accurat examination of their coats could be made. What could be seen was sudde dilatation of the calibre of the vessels, which had ruptured at the same time those in the brain from some sudden increase of the already high arterial pre sure.—*Med. Times and Gazette*, March 19, 1881.

—

Nerve-stretching in Locomotor Ataxia.

The operation of nerve-stretching as a means of treating locomotor ataxy w introduced, it will be remembered, by Dr. LANGENBUCH, who recorded a star ling improvement in a case so treated, the intense pains and considerable atax having almost entirely disappeared after the operation, and the diminished sens bility having returned to the normal. Symptoms of similar character and marked degree persisted in the upper limbs, and, indeed, appeared to have becom more intense. Hence it was decided, three months later, to stretch also th nerves of the arms. While the patient was under the influence of chloroform a epileptic fit occurred and he died. The spinal cord from this important case w given for microscopical examination to Professor WESTPHAL, who has just pub lished the results in the *Berlin. Klin. Wochenschrift*. The cord was seriousl

crushed at certain places, probably in the process of removal. Other parts, however, were in good condition for examination, especially the lumbar enlargement, the upper part of the cervical region, and small parts of the dorsal region. These parts showed nowhere the clear tracts which indicate the presence of sclerosis in hardened cords. Microscopical examination in glycerine showed no granule corpuscles nor the translucent appearance which indicates degeneration. After tinting, the posterior columns were found intact throughout, without a trace of sclerosis or of atrophy of the nerve-tubules. The periphery of the posterior columns, in which a slightly paler colour had been noted with the naked eye, tinted more deeply than the rest, and here the regular arrangement of the nerve-fibres was wanting, and the condition showed clearly that this appearance had only arisen from an injury during the removal of the cord. Sections from the dorsal region and the upper cervical region showed also a perfectly normal white substance, nowhere any trace of sclerosis or of atrophy. No abnormal changes were found in the gray substance, and the nerve-fibres of the anterior and posterior roots exhibited also no trace of atrophy.

It is certain from these facts that the case was not one of posterior sclerosis. Can we (Westphal asks) from these facts draw the inference that in a certain stage of tabes the disease may exist as a neurosis without structural changes, and that the degeneration of the posterior columns represents a later and consecutive change which has nothing to do with the special symptoms, in accordance with the older view held by Trousseau? This conclusion seems incompatible with the fact that in all cases examined hitherto, without a single exception, structural changes in the posterior columns have been found. Moreover, the case of Dr. Langenbuch does not, he urges, point to such a conclusion. The clinical history has only been very briefly recorded, but the facts as stated are altogether peculiar. The affection had been of very rapid development; although the symptoms were advanced, they had only existed for a few months, and the arms were considerably affected a few months later. The case thus resembles those of so-called "acute ataxy," such as occur spontaneously or after acute febrile diseases, and which have a course altogether different from that of ordinary tabes, often ending in complete recovery. The nature of these cases is unknown.

Langenbuch was inclined to regard his case as one of a primary affection of the peripheral nerves, but, unfortunately, the large nerve trunks could not be removed at the post-mortem examination. It is, however, noteworthy that at the operation the left sciatic was seen to be "reddish and somewhat swollen."

In publishing these facts, Westphal does not desire to discountenance the operation in other cases in which the existence of a spinal lesion is undoubted, since, as he rightly points out, experience rather than theory must be our guide; but he strongly urges, and with reason, the great importance of a thorough and skilled examination of the nerve symptoms in all cases before the operation, that we may know whether the cases so treated are to be regarded as examples of true posterior sclerosis or not.—*Lancet*, March 26, 1881.

—

On the Disappearance and the Localization of the Knee Reflex.

The value of this reflex, as a means of diagnosis in diseases of the spinal cord, was first established by Professor Westphal, of Berlin, who designated it the "knee phenomenon." The term commonly employed—"patellar tendon reflex"—is objectionable, as involving the idea that it is a simple reflex process connected solely with the patellar tendon. A much better name is that given to it by Dr. Hughlings-Jackson—the "knee-jerk." It consists, as is well known, in the contraction of the quadriceps extensor cruris following, in health, a blow on the

patellar tendon. Westphal believes that it is no simple reflex action, but a complex phenomenon, depending primarily on the muscular tone of the quadriceps extensor, and secondarily on a reflex. In typically developed cases of gray degeneration of the posterior columns of the spinal cord (tabes dorsalis or locomotor ataxy) this reflex is absent, its disappearance is one of the earliest symptoms of this degeneration, frequently preceding the disturbances of sensation and motion that mark the full development of the disease. Its disappearance implies disease of the reflex track, or, excluding the nerves and their roots, it implies disease in the lumbar enlargement of the spinal cord. Professor WESTPHAL, in an address to the Medical Society of Berlin, has sought to answer the further questions—(1) In those cases where the disappearance of the knee reflex forms the first symptom of tabes, is there already anatomical change in the lumbar posterior columns? and (2) If so, where; that is, in the postero-external column (root-zone of Charcot) or in the postero-median column? An answer to these questions need not be looked for in cases where the fully developed disease has caused death, but Professor Westphal thinks the following case throws some light upon them: In March, 1877, a male patient aged thirty-two, was admitted into Charité suffering from mental aberration. His family history showed a strong tendency to psychical and nervous disease. A year before the above date the patient complained of weakness of sight, but ophthalmoscopic examination gave a negative result. Six months thereafter he became completely blind, and optic atrophy was now found. The mental disease for which he was admitted appeared in a marked form eight days before admission. His blindness was very nearly total on both sides—the pupils insensitive to light, but reacting on accommodation; his articulation was slightly affected; but with these exceptions there was no alteration in the nervous system. Sensation and motion were perfect, and his gait was the normal walk of the blind. The knee reflex on both sides was normal. His mental aberration consisted in moderate intellectual weakness with delusions. In June, 1878, the delusions had all disappeared, the intellectual weakness alone remaining. Next he became hypochondriacal, and his articulation was more affected. Ultimately he spoke nothing, became uncleanly in his habits, and refused nourishment. In 1879 he was again in the condition of simple intellectual weakness. During all this time there was no change in sensation or motion. The knee reflex was proved from time to time, and failed for the first time in October, 1879, in the right leg, that of the left being still weakly present. In December, 1879, diarrhœa with bloody stools appeared; and in January, 1880, the patient died with fever, delirium, and tremor of the limbs. Five days before death the knee reflex failed in the left limb also. The post-mortem examination showed slight membranous exudation on the surface of the dura mater, cloudiness but no adhesion of the pia mater, and atrophy of the optic nerves and tracts. To the naked eye the spinal cord appeared normal, but hardened in bichromate of potash, it showed degeneration of the postero-external columns, and in a less degree of the posterior parts of the lateral columns. The degeneration was most extensive at the lower part of the cord, gradually diminishing upwards, and nowhere affecting the postero-median column. It showed microscopically, numerous "granule corpuscles," considerable disappearance of medullated nerves, and thickening of interstitial tissue; not, however, the complete atrophy of fully developed gray degeneration. The gray substance and posterior roots were normal. Professor Westphal considers himself justified in arguing that the degeneration of the postero-external column produced failure of the knee reflex. The degeneration in the lateral column could not be the cause, for (1) frequently in tabes, when the knee reflex fails entirely, the lateral columns are quite normal, and (2) the lateral columns have been found diseased to the lumbar enlargement,

without the slightest decrease of the knee reflex. The argument, he remarks, is supported by the following facts: (1) the almost constant failure of the knee reflex in tabes dorsalis, combined with the almost constant occurrence of degeneration of the postero-external column as its first change; and (2) the occurrence of complicated cases of spinal disease, where the knee reflex is retained, and where also uniformly the postero-external column is healthy.

Professor Westphal then proceeds to discuss certain fallacies with regard to the knee reflex. He points out that although many authors have given cases of developed tabes with the knee reflex retained, no case has been published where the ordinary symptoms of tabes were present, with the exception of the absence of the knee reflex, and where the post-mortem examination has shown gray degeneration of the posterior columns to the lumbar enlargement. Numerous cases, he says, of disseminated gray degeneration with muscular spasm and even foot clonus have been brought to him as tabes dorsalis. With regard to the 1.56 per cent. of healthy individuals in whom, according to Berger, the knee reflex fails, Professor Westphal says he never met with a case of failure in an undoubtedly healthy person, but he points out that the reflex is difficult to produce (1) in those who have short, thick legs, or (2) short patellar tendons not furnishing length sufficient for the necessary vibration; and (3) the reflex will be absent where the muscular tone of the quadriceps extensor is absent, *e. g.*, in extensive acute disease of the gray matter of the cord, etc. The absence of the knee reflex in a seemingly healthy individual, Professor Westphal would consider a sign of latent tabes, which may remain undeveloped for years, or, since the disease is not necessarily and absolutely progressive, may never be developed. Naturally, the gradual disappearance of the phenomenon if observed has a much higher diagnostic worth than the simple discovery of its absence. The knee reflex, Professor Westphal remarks, ought to be proved in all obscure cases of nervous disease—*e. g.*, in hypochondria. He has met with several cases of hypochondria with no spinal disease, and the knee reflex retained, where tabes dorsalis has developed itself later.

What was the nature of the case discussed above? The lightning pains of tabes and the disturbance of sensation and motion all failed here. The degeneration in the posterior parts of the lateral columns occupied the position of the "crossed pyramidal tracts"—*i. e.*, of the fibres which cross at the anterior pyramids. The disease could not be followed into the pyramids, and this, along with the fact that no centre of disease was found in the cerebrum, shows that it was not a case of secondary descending degeneration, but a primary degeneration of the above-mentioned system of fibres. Whether the degeneration of the postero-external columns is also a "system disease"—*i. e.*, a disease of a column of functionally equivalent nerve-fibres—is a much more difficult question, chiefly because the results of development and pathology are not yet at one in the differentiation of the two parts of the posterior column. The localization of the knee reflex, however, in the postero-external column seems thoroughly justified. Disease of that column appears on reaching a certain intensity to destroy the tone of the quadriceps extensor, and thereby the knee reflex, giving us a means of most accurate (or even, as Professor Westphal says, elegant) diagnosis in diseases of the spinal cord.—*Med. Times and Gaz.*, March 12, 1881.

—

On Spastic Spinal Paralysis.

In an article in the *Hospitals-Tidende*, series 2, Band vii. Dr. A. FRIEDENREICH gives a short sketch of the history and symptomatology of this form of disease, and discusses the question, how far it is in itself a disease, and whether

it has a constant course, and a constant pathological basis. He refers to the cases of spastic spinal paralysis with a more or less acute course described by others, especially Veldens and Hench, and relates a case of similar nature which had come under his own observation.

A man aged 39 presented in as marked a form as possible the muscular rigidity, the spastic gait, and the enormously increased tendon-reflexes, characteristic of spastic spinal paralysis. The disease had probably been caused by the influence of alternations of heat and cold; it began with symptoms which were referred to rheumatic fever, and had apparently reached its culminating point when the patient was admitted into the Communal Hospital at Copenhagen. The duration of the illness was about three months and a half, and ended in almost complete recovery. The author then notices the literature treating of the transitional forms between spastic spinal paralysis and other forms of chronic myelitis, and finally speaks of the pathology of the disease. After noticing the *post-mortem* appearances described by Stofella, Westphal, and Charcot, he describes the following case:—

The patient was a man aged 31, who had been somewhat imbecile from infancy. His illness began about half a year before he came under observation, and he presented in the most distinct form the motor disturbances characteristic of the disease. He died about a year and a half after the commencement of his illness. The spinal cord was everywhere softened, being in some parts almost fluid. On minute examination, numerous portions were found, varying from microscopic smallness to the size of a pea, while the tissue was completely broken down and reduced to detritus, while at the circumference of the completely destroyed portions there were generally found parts of which the structure was still recognizable, while networks of the neuroglia were found, if not destroyed, to be filled with an amorphous more or less granular mass, coloured in various shades by carmine, and having scattered roundish nuclei; in other parts there was a quite amorphous exudation, which was coloured rather strongly by carmine, and contained similar nuclei. There was also found, diffused over nearly the whole mass of the spinal cord, but in very varying degrees in different parts, hypertrophy of the interstitial tissue, while the nerve-fibres were partly thrust asunder, and showed here and there distinct swellings, especially of the axis-cylinders. There was no indication of a systematic diffusion of the interstitial changes. The gray substance, especially in the cervical region, showed very scanty ganglion-cells, there being often only a single one in a section of the whole anterior cornua, while the cells of the posterior cornua were on the whole better preserved. Of the existing cells, some were rather small and highly pigmented, while others were of normal size, but very pale, and having an abnormal tendency to a globular shape. The central canal was obliterated throughout; the pia mater was thickened, and very adherent in some parts.

Dr. Friedenreich believes that he is justified in drawing the following conclusions: 1. Spastic spinal paralysis is not an independent disease, but a congerie of symptoms which may occur in various affections of the spinal cord. 2. The phenomena depend on an increase of the tendon-reflexes, in combination with partial preservation of voluntary motor power. 3. Where the phenomena of spastic spinal paralysis occur, they may indicate sclerosis of the lateral columns, but, in the present state of science, they do not prove it. Still less can they prove the existence of an exclusive or only transient affection of the lateral structures of the pyramid.—*London Medical Record*, March 15, 1881.

Œdema of the Right Arytenoid Cartilage.

Dr. E. MARTET (*Annales des Malad. de l'Oreille, du Larynx, etc.*, Dec. 880) relates the case of a sergeant-major who, with a history of great hoarseness nd dysphagia of three days' duration, presented a round swelling of the right rytenoid eminence, of the dimensions of a medium-sized grape. Its mucous embrane was stretched, shining, and of a grayish colour. The epiglottis was red nd slightly swollen, the remainder of the larynx being normal. The œdematous rt was twice touched with a solution of chromic acid (1 in 4), and in three days covered its normal appearance, the hoarseness and dyspnœa having completely appeared. The etiology of the affection appears to have been the excessive e of the voice whilst commanding, and the effect of damp cold, in a person of inking habits. The author also mentions a case of syphilis of the larnyx, companied by œdema of the glottis threatening asphyxia, in which the latter mptom was successfully relieved by applications of chromic acid.—*Lond. Med. ecord*, April 15, 1881.

—

Uræmic Dyspnœa.

M. G. SÉE (*Le Practicien*) has published notes of the case of a young woman tacked by urgent dyspnœa, with great oppression and cyanosis. There were a int systolic apex-murmur, and a few râles over the lungs posteriorly, but noing sufficient to account for the symptoms. The urine was very albuminous. here was no œdema. She died in a few days. The kidneys were large and d. Mr. Sée lays down the rule that, when a person is attacked with dyspnœa ithout obvious cause in the thoracic organs, the urine should be examined for bumen. He relates two other cases, in which the dyspnœa simulated spasmoic asthma, and was not readily diagnosed on that account.—*Lond. Med. Reord*, April 15, 1881.

—

Treatment of Pleurisy in Children.

Dr. J. LEWIS SMITH, in a paper upon this subject (*Med. Record*, April 9, 881), speaks of the treatment appropriate to each of the three stages:—

1. The stage which precedes the effusion; 2. The stage of effusion; and 3. he stage of absorption and convalescence.

In the beginning of the disease measures should be adopted which are appropriate for reducing inflammation and limiting exudation. The abstraction of lood in idiopathic pleurisy may be beneficial if judiciously employed, but only ne or two or three leeches should be employed in a robust child two, three, or our years old. As a rule, the loss of blood is injurious in all cases of secondary leurisy, such as follows scarlet fever, etc., and also if the quantity of effusion is reat. Emollient and simply irritating poultices are serviceable in the first stage, nd he recommends a mixture of *one* part of mustard to *sixteen* of linseed. It hould be made very wet, spread thin, applied over the chest in front and beind, covered with oil-silk, and changed twice in twenty-four hours. For children under six or seven months of age, rubbing the chest with camphorated oil, nd applying a simple poultice, may be sufficient.

Blistering at this early stage of the disease should not be employed, as it increases the inflammation, and Dr. Smith has seen a case which terminated fatally, n which there was found an increased area of inflammation, corresponding exactly in situation, size, and shape to a blister that had been applied.

The indications for the use of internal remedies in the first stage are to diminish the frequency of the pulse, relieve the pain, and allay the cough.

To a child *three* years old the tincture of aconite may be given in doses of half a drop, and for a child *six* years old in doses of *one* drop, every three hours for

two or three days. In the first stage of primary pleurisy the cardiac sedati may be used; but digitalis is a safer and better remedy in all other cases, and also can be used in the second stage.

To a child *two* years old the tincture of digitalis may be given in doses of *drop every three hours*, and to a child five years old *two* drops with the sa interval. An opiate is ordinarily required: Dover's powder, one to three grai every three hours. Hyoscyamus may be used to relieve the pain and coug digitalis may be combined with an opiate; and morphine and aconite may combined.

In secondary pleurisy digitalis is preferable to aconite.

In the *second* stage, unless the effusion is small, measures designed to remo it are required. The propriety of using blisters in this stage is very doubtful.

A relaxed condition of the bowels favours absorption of serous effusion. D phoretics do not aid much in the removal of the fluid. Pilocarpine produces depressing effect which renders it unsafe.

Diuretics and tonics are beneficial. Digitalis, with the acetate of potash very serviceable.

℞. Infus. digitalis ℥iv; potass. acetat. ʒj.—M. S. Teaspoonful every th hours, to a child four or five years old.

Bitter tonics are especially useful in this stage, and the acetate of potash m be combined with a decoction of cinchona, with good results. A full amount nutriment should be taken, with but little fluid. Of course, the suggestion use a dry diet and diminish the quantity of drink is not applicable to young ch dren. If the appetite and the general health are good, and there are no sym toms due to the presence of the fluid, but little medication is necessary. If th are such symptoms and the fluid does not disappear, the question of surgi interference arises, and the indications for it are the following:—

First.—Oppressed breathing due to the liquid present, whether it be se fibrinous, purulent, or hemorrhagic.

Second.—If there be flat percussion note over the entire affected side, with placement of the heart, even if there be no dyspnœa, for the latter may oc suddenly.

Third.—Moderate effusion, without material decrease in quantity by abso tion after some weeks of treatment. There is danger that catarrhal pneumo terminating in cheesy pneumonia and tuberculosis may occur in portions of compressed lung. Besides, the longer the lung is compressed, the slower wil return to normal expansion after the pressure has been removed.

Fourth.—A moderate quantity of fluid co-existing with disease of the oppos lung, or of the lung of the affected side.

Fifth.—Extension of the inflammation to the pericardium. Pericarditis as extension of the inflammation is not infrequent.

Sixth.—The existence of valvular lesion of the heart.

Seventh.—The presence of pus; empyema.

The operation of thoracentesis should be performed in the eighth interco space, on a line perpendicular with the angle of the scapula. The admission air to the pleural cavity should be carefully avoided. The thickness of the th racic wall is about half an inch; in emaciated children it is less. Introduction the canula to the depth of *one inch* is sufficient to pass beyond the exudation a allow the liquid to flow through the canula. The sharp needle should not used. Washing out the pleural cavity is unnecessary; it is injurious rather th beneficial, except in cases in which the pus is offensive. To empty the pleu cavity and approximate the pleural surfaces is the indication. Dr. Smith thin there will be a reaction against the removal of a portion of the ribs in cases empyema.

Idiopathic Enlargement of the Heart.

Under the term enlargement of the heart are generally included three anatomical conditions: first, where the cardiac cavities are increased and the cardiac alls thickened in direct ratio—simple enlargement; second, where the cavities re increased and the walls thickened, but the cavities in higher degree—excenic or dilated enlargement; and, third, where the cavities are actually diminhed by the thickening of the walls of the heart—concentric enlargement. oubt has been thrown on the existence of this last class of cases; and, in some cent remarks on the subject, Professor FRÄNTZEL, of Berlin (*Berl. Klin. Voch.*, Feb. 1881), protests against the terms excentric and concentric cardiac pertrophy. His distinction of idiopathic enlargement of the heart into dilatan *with* and dilatation *without* hypertrophy is undoubtedly the expression of a fference of first importance clinically. Hypertrophy, speaking broadly, means e; its absence indicates impending death. The conditions of its development e chiefly the vigour of the patient and the gradual development of the resistce producing the enlargement. For the left ventricle, its presence is shown high tension of the radial arteries, abnormally resistant heart's impulse, and rked or ringing second sound in the aorta; while, for the right ventricle, the ly sign is marked or ringing second sound in the pulmonary artery. As to the rcussion of the heart, Dr. Fräntzel emphasizes that it is not simply what we find, t the interpretation thereof, that is important. The actual projection outline the heart, he believes, it is impossible to discover; but should the percussion te over the body of the sternum be duller than over the manubrium, he coners we may diagnose cardiac enlargement to the right, that is, in general, atation of the right ventricle. A dulness extending beyond the usual triangle cardiac dulness indicates, in the absence of disease of the neighbouring organs, affection of the heart, either fluid in the pericardium or dilatation of a cardiac rity, according to the position and shape of the dulness. The obverse of this, wever, is by no means invariably true. A dulness not extending beyond the ove-mentioned triangle is in no way a sure indication of the absence of dilatan. A heart's dulness of normal dimensions in a *wide* thorax, according to Dr. ntzel, indicates dilatation; and again, in the barrel-shaped chest, where no rt's dulness ought to be found, the presence of dulness at all indicates a most nounced dilatation. Such a diagnosis made some time before death may be tradicted, Dr. Fräntzel says, by the necropsy, but this he holds to show sim- that dilatation, like hypertrophy, may regress on the causes ceasing to act.

In enumerating the causes of idiopathic enlargement of the heart, Dr. Fräntzel kes special mention of those cases of a single great bodily exertion which, by te distension of the left ventricle, may cause irreparable cardiac debility, lead- to rapid death. This, we may presume, he has observed mostly in persons ll on in years. A rush to catch a train may cut half a score of years or more a comparatively healthy man's life. In discussing obstructions to the circuon in the lungs and kidneys as causes of cardiac enlargement, he seeks to plain the enlargement of the left ventricle in kidney-disease by the obstruction the renal circulation. He ignores apparently the frequent want of concomicy between the amount of cardiac enlargement and the degree of renal disease, l refuses the more modern explanation which regards both diseases as local nifestations of a common disease, in all probability acting and reacting on one ther. With regard to the large class of cases in which cardiac enlargement ttributed to arterial sclerosis, Dr. Fräntzel agrees with Traube in considering h the arterial sclerosis and the cardiac enlargement to be the results of a comn cause, namely, high systemic tension, produced either by gluttony and

drunkenness, or by hard labour. Both classes, he says, benefit much by purgatives, combined in the former with opium, in the latter with absolute rest.—*London Medical Record*, April 15, 1881.

—

Pulsus Bigeminus.

Dr. FRANZ RIEGEL (*Deutsches Archiv für Klin. Med.*, Feb. 1881) contributes a careful study of two such cases, with numerous graphic tracings. The one case had a systolic, mitral, and tricuspid murmur, with 80 apex-beats per minute, 80 visible undulations of the jugular veins, and 40 radial pulsations. Two apex-beats and jugular undulations were close together, and corresponded to one radial pulsation. The other case had no venous undulation, and had 88 heart-beats, with 44 radial pulsations. These cases, then, were similar to those described by Leyden and others, as instances of independent contraction of one ventricle without the other—the right contracting twice for one systole of the left. But the author shows from sphygmographic evidence that each radial pulsation is followed by a faint wave, imperceptible to touch, and synchronous with the second of the redoubled cardiac impulses. He, therefore, holds that such cases have been erroneously apprehended, and that both ventricles simultaneously contract, although the second is fainter than the first of the double heart-beats, and does not send out a wave strong enough to reach the wrist.—*London Medical Record*, April 15, 1881.

—

Treatment of Vomiting in Phthisical Patients.

M. FERRAND, physician to the Hospital Laennec, sums up as follows, in *L' Union Médicale*, the principal indications presented in the vomitings of consumptive patients. The forms of vomiting are: 1. the mechanical vomiting resulting from the excitation of the respiratory nerves, which is sometimes combined with a certain degree of pharyngeal or gastric irritation; 2. gastric vomiting properly so-called; central and bulbar vomiting. These varieties of vomiting differ, not only in their mechanism, but also in their period of appearance, and in the nature of the vomited matters, etc. The mechanical vomiting of phthisical persons, which may be called direct vomiting, occurs at the outset of the disease. It brings up substances which are in a large measure alimentary. The first indication in this case is to calm the cough. This, however, is more easily said than done. Emollients, alkaline, and soothing gargles should be employed. When the irritation of the pharnyx is deep-seated, modifying astringents (alum, tannin, confection of roses, etc.) should be resorted to, and even such remedies as tincture of iodine, nitrate of silver, or ammonia. What are most often employed are the narcotics, the fumes of belladonna, datura, and then anæsthetics and antispasmodics. In this contingency, M. Woillez recommends touching the pharynx with a solution containing one-sixth of bromide of potassium, Gastric vomiting is the most common of digestive disorders in phthisis. It occurs in three-fifths of patients, according to Andral, and in four-fifths, according to Louis. It is the vomiting of the middle period of the disease. These matters are not purely alimentary; they are substances more or less changed by the digestion and fluid. They include also mucus and bile. There are four varieties of gastric vomiting. 1. Vomiting from apepsia. For this, bitter and tonic digestives are to be employed, or, in case of need, an emetic; in default of the latter, chloral, and chloroform in preference to ether; and diastase, because of its peptic qualities, may render real service in these cases. 2. Vomiting from 'hypercrinia,' observed especially in cachectic patients, is combated by absorbents (magnesia, charcoal) or astringent powders (rhatany, calumba). Powdered opium renders great ser-

vice in these conditions. 3. The vomiting from convulsive gastralgia demands the administration of narcotics (opium, chloral, ether). The application of ether-spray to the epigastric region and the back has given good results. 4. Vomiting by gastric irritation. Here the diet must be regulated, the meals must be given at fixed times, and milk-diet prescribed. Alkaline remedies and iodide of potassium in small doses should be given. Opiate blisters should be applied, and in case of failure, revulsive agents (tincture of iodine and blisters) should be used without fear. Central or bulbar vomiting may occur at the outset of the tuberculosis, but usually at an advanced stage. It may be symptomatic of an encephalic irritation, or the effect of bulbar anæmia. The vomited matters consist mostly of mucus and bile. The therapeutic agents at the disposal of the physician are first chloral; then chloroform, opium, and morphia, as well as bromide of potassium, in doses of 1 to 2 grammes (15 to 30 grains) at meal times.—*Lond. Med. Record*, April 15, 1881.

Treatment of Dysentery with Enemata of Cold Water and finely crushed Ice.

After trying various methods of treatment, MICHAILOW (*Mediz. Obosr.*, vol. iv. Aug. 1880) has ended at last with the method of enemata of cold water and finely crushed ice, which, he says, has not failed him in a single case for four years. It proved especially successful in the cases of his own children. A short description of two cases follows. Quinine, in the form of Botkin's cholera drops, was administered internally in all cases. (Compound tincture of quinine, Hoffmann's anodyne spirit, of each half an ounce; hydro-chlorate of quinine, one scruple; dilute hydrochloric acid, half a drachm; tincture of opium, half a drachm; peppermint-oil, fifteen drops.) The diet consisted of *bouillon*, milk, and eggs; the drink was cold water and red wine. The enemata were made in the following manner: Ice was crushed to paste; from this mass of ice two glasses were taken for grown-up men for every enema; for children, according to age, beginning with half a glassful, and so on. Water was then added while the ice floated. It was then poured into a glass funnel connected with a long tube. This funnel, fixed on a stand, remained near the sick bed; in other words, the apparatus remained in action until the mass of ice melted and flowed slowly into the rectum, which process lasted about one or one and a half hours. The enemata were employed every two hours, then every three and four hours; finally, twice or three times daily. The author succeeded in all cases in curing the disease in eight or ten days.—*London Med. Record*, March 15, 1881.

On the Hygienic Treatment of Biliary Calculi.

Professor BOUCHARDAT, who is the leading authority in France on medical dietetics, recommends (*Bull de Thér.*, Aug. 1880), for the treatment of biliary calculi, that the patient should abstain from bread, cereals, eggs, and nitrogenous food in excess; sorrel, tomatoes, strong liquors, shell fish, and cheese; that he should eat ordinary vegetables, preferring those rich in potash to those which are rich in soda. He should also employ an indirect alkaline treatment in the form of malates and citrates, as they are contained in fruits, and drink light red wine diluted with water. He should keep the bowels free by taking every morning a teaspoonful of tartrate of potash and soda and sulphate of soda in equal parts. He should take moderate exercise. The action of the skin should be stimulated by washing, frequent friction, and shampooing by the hand moistened with a few drops of perfumed oil. Every week from one to three baths should be taken, each bath containing 100 grammes of carbonate of potash, 2

grammes of essence of lavender, and 5 grammes of tincture of benzoin, followed by lengthened friction and shampooing. With the object of the expulsion of the calculi, the patient should take, night and morning, one to three *perles* of essence of turpentine, and one or two *perles* of ether. They may be taken with the meals, but in preference between them. To prevent the formation of calculi, the patient should take for ten days, night and morning, before each repast, a pill containing one decigramme (1½ grain) of tartrate of potash and lithia; for ten subsequent days he should take full doses of acetate of potash, with a light aperient night and morning; for ten subsequent days, every day a pint and a half of water containing tartrate of potash and soda. During the spring, on rising in the morning, he should take, for a month, 120 grammes of the juice of lettuce, chicory, and dandelion, equal parts, with five grammes of acetate of potash. He should spend a season at Pougues, Vals, or Vichy.—*London Medical Record*, March 15, 1881.

—

Treatment of Psoriasis by Baths of Sublimate.

Having to deal with a case of obstinate psoriasis which defied all their efforts for four months, Dr. Voss and Dr. SPERK (*Gaz. Med. Chir. de Pesth*) hit upon the plan of trying baths of sublimate only. The result may be truly designated as wonderful. After a series of fourteen baths, the skin lost its reddish colour, the epidermis desquamated in large lamellæ, the integuments finally, which were thickened and infiltrated, became supple and elastic. However, during the course of treatment, there were fresh eruptions, but the new patches were less injected, and covered with thinner epidermic scales. Scratching did not bring on any sanguineous exudation. Forty-six baths completed the cure. So remarkable and unexpected a result encouraged Dr. Voss to persevere in the same path; four other cases of inveterate psoriasis treated in the same way obtained a good result in a comparatively short time. The first patient took thirty-two baths, the second forty, and the third forty-eight, and at the time when this report was written, a fourth patient had greatly improved, but was not completely cured. As far as possible the baths were given daily; the water was at a temperature of 27–29 deg., and the patient was required to remain in them from thirty to forty minutes. Dr. Voss has never observed the symptoms which are easily caused by mercurial preparations, such as salivation, swelling of the gums, etc. The advantages of this new treatment may be described under the three heads of (1) rapidity; (2) facility of administration, as baths require but a very short time, and the patient is not obliged to interrupt his daily occupations; and (3) cleanliness. The patient is also able to dispense with topical applications of all sorts, which generally exhale a more or less unpleasant odour.—*London Med. Record*, April 15, 1881.

Surgery.

Multiple Cutaneous Gangrene.

In 1878, Professor Simon first called attention to this comparatively rare disease, which for the most part affects children of various ages, and has a malignant character. Dr. EICHHOFF (*Deutsch. Med. Woch.*, Aug. 21, 1880) recently observed a case of this kind at the Breslau clinic for cutaneous and syphilitic diseases. The child, aged 8, was first seen in April, and was then suffering from extensive eczema of the face, breast, and back. Constitutional symptoms were not marked at this time, and the eczema rapidly yielded to appropriate treat-

ment. In May the child was again brought to the clinic, when its general health was found to be much depreciated. The back had been covered with dark-red patches, the largest about the size of a millet-seed. Vesicles soon appeared above these patches, but they rapidly collapsed, leaving ulcers, which soon became gangrenous. The sloughing extended deeply down into the subcutaneous connective tissue. Local and constitutional treatment caused these sloughing ulcers to heal, with cicatrices resembling those of variola. Some time after this a corneal ulcer developed, and, simultaneously with its appearance, the head became affected with gangrenous ulcers. The latter slowly healed, leaving deep cicatrices. A second exacerbation occurred in June, and again a corneal ulcer was one of the complications. The ointment, applied locally, consisted of 15 parts each of camphor and myrrh, with 100 parts of vaseline. The pathogenesis of this affection was said to resemble that of ordinary bed-sores. The appearance of the corneal ulcers was explained by the depreciation of the child's general health and insufficient *vis à tergo*.—*London Medical Record*, March 15, 1881.

—

Tar, Soot, and Tobacco Cancer.

The workman in coal-tar and paraffin manufactories suffer very frequently from acute and chronic inflammations of the skin. Volkmann has already described several cases, in which true epithelial cancer was developed from these chronic inflammations, and TILLMANNS (*Deutsche Zeitschr. für Chir.*, Band xiii. Heft 5 and 6) now adds another, ending fatally after numerous operations. This form of cancer, and also chimney-sweepers' cancer, and epithelial cancer of the lip and tongue in inveterate smokers, the author attributes to irritation by the products of imperfect combustion; not, however, saying that this is the actual cause, but simply that it is the exciting cause in those disposed to the development of cancer.—*London Med. Record*, April 15, 1881.

—

Secondary Suture of Nerves.

Among the advances in nerve pathology and therapeutics of the last few years, not the least interesting and important have been the practice and results of surgical interference. The operation of nerve-stretching has established itself as a recognized proceeding, and recent experience is rapidly extending its sphere of usefulness, although its *rationale* is involved in considerable obscurity. The primary suture of divided nerves has been practised for several years, and many recorded and unrecorded cases testify to its value. Quite lately, however, the secondary suture of nerves has been practised, and although not with uniform success, yet with most encouraging and, we may add, surprising results. The best test cases are those of union of severed motor nerves, for the return of sensation in parts supplied by a divided and then sutured nerve is open to another explanation than that the nerve trunk has again become capable of conducting sensory impressions. For this reason a case of Langenbeck's, of secondary suture of the musculo-spiral nerve, is very valuable. The patient, a labourer, thirty-one years of age, received a severe contusion of the outer side of the right arm below the middle, which was attended with paralysis of the extensor muscles of the forearm and hand. An abscess subsequently formed and was opened. Two-and-a-half months after the injury, as the paralysis continued, Langenbeck cut down upon the divided nerve, freed its ends, which he found lying two centimetres and a half apart, and united them by a catgut suture. Although there was considerable tension, healing took place by first intention, and nineteen days afterwards the extensors reacted to the induced current, and after a month and a half

considerable active extension movements were possible. Mr. Hulke has brought forward at the Clinical Society a case in which he had united the cut ends of the median nerve nearly six weeks after the injury, and another case in which he practised a similar operation on the ulnar nerve fifteen weeks after division, and in each instance there was distinct evidence of restoration of function. Esmarch and Létiévant have each had a case of suture of the musculo-spiral nerve, the former successful. These and other like cases afford great encouragement not only to unite by suture the cut ends of nerves in recent wounds, but, where necessary, after cicatrization is complete.—*Lancet*, March 19, 1881.

—

Suture of Nerves and Tendons.

The case communicated by KRAUSSOLD (*Central. für Chir.*, 1880, No. 47) is of some interest, as showing to what an extent suture of these structures may be employed with benefit. A female patient, melancholic and suicidal, had made a transverse cut on the palmar surface of both forearms, an inch and a half above the left wrist-joint, and two inches and a half above the right. On the left side, the radial and ulnar arteries were divided; the radial and ulnar nerves completely, the median nerve more than three-fourths; also the tendons of the flexor sublimis digitorum entirely, and those of the flexor profundus digitorum partly. On the right side, the radial, ulnar, and interosseous arteries were divided, the radial and median nerves completely, the ulnar nerve two-thirds, also the tendons of the flexor profundus and sublimis, and of the flexor longus pollicis. Both ends of the arteries were ligatured, and the nerves and tendons brought together with sutures. Three weeks after the injury, sensibility was perfectly normal and active, and passive movements were all possible, although still slow and weak. A small defined spot on the ball of the little finger became gangrenous, but otherwise there was no fever or reaction.—*London Med. Record*, April 15, 1881.

—

Unilateral Injury of the Spinal Cord.

The patient in this case, reported by SCHULZ (*Cent. für Nerven.*, 1880, No. 15), a male, aged 29 years, received a stab in the back between the spines of the fifth and sixth dorsal vertebræ, a little to the right of the middle line, and about two inches in depth. Soon afterwards there appeared paresis and hyperæsthesia of the right lower limb, anæsthesia (with intact motive power) of the left lower limb, involuntary passage of feces, and retention of urine. Half a year later, the right lower limb showed paresis, with laboured but not ataxic movement. It was also thinner than the left, but presented no difference in colour or temperature. The left limb showed also no ataxy. The muscular sense of the left limb was normal, that of the right diminished. On the right side the skin was hyperæsthetic as high as the seventh dorsal vertebra; above this, as high as the sixth, it was anæsthetic. The sensations of tickling, touch, and pain were all increased on the right; the sensation of temperature was normal. For electric currents, the skin on the right side, both limb and trunk, was very sensitive; while, on the left side, it was normal, or even diminished The left side showed no actual anæsthesia, but a marked analgesia; and, corresponding to the anæsthetic zone of the right side at the sixth dorsal vertebra, was a zone of hyperæsthesia. The tendon-reflexes were normal on the left side, much increased on right. The electric irritability of the nerves and muscles was alike on both sides. —*London Med. Record*, April 15, 1881.

Syphilitic Disease of the Spine.

In the current number of the *Annales de Dermatologie et de Syphiligraphie*, M. FOURNIER reports at great length a very interesting case of Pott's disease caused by syphilis. The patient, a coachman, aged 56, was admitted into the Hôpital St. Louis in July, 1876. The man had had venereal disease in his youth, but no clear history of syphilis could be obtained. He stated that his health had always been good until a few months before admission, when he gradually lost his appetite, and began to suffer from pain in the loins, which afterwards extended to the legs. M. Fournier could not find anything wrong with the spine, but the patient had well-marked syphilitic disease of the testis, gummata of the skin, etc. The testis and the gummata were much benefited by antisyphilitic treatment, but the general health declined, ascites and pleural effusion appeared, and the man died about three months after admission. At the post-mortem examination, ample evidence of syphilis was found in various parts of the body, as well as the following condition of the spine. Antero-posterior section showed the bodies of the third and fourth lumbar vertebræ, in their posterior half, to be infiltrated by a yellow cheesy material. The posterior three-fourths of the intervertebral substance was also destroyed, a cavity containing purulent fluid being left. The intervertebral substance between the fourth and fifth vertebræ was softened, and infiltrated with pus in its posterior half; and there was a cavity in the body of the third lumbar vertebra. Under the microscope, the third, fourth, and fifth lumbar vertebræ presented the typical appearances of condensing osteitis, with purulent and caseous infiltration, exactly as is seen in gummy osteomata. There was also double psoas abscess. The further examination was carried out by M. Hayem, who found a gumma on the fourth lumbar nerve at the point where it left the foramen. In this situation there was also another gummy growth, which appeared to have originated in the periosteum of the corresponding vertebra. Above the gumma the nerve was affected by interstitial neuritis, and there was partial atrophy of the nerve-tubules. The third and fifth lumbar nerves presented only appearances due to irritation and pressure, without decided alteration of the nerve-elements.—*British Med. Journal*, April 2, 1881.

—

Transparent Cysts of the Eyelids.

From a careful examination of the transparent cysts which are often found on the free edge of the eyelids, Dr. DESFOSSES (*Archives d'Ophthalmologie*, Dec. 1880) believes them to be formed from modified sudoriparous glands. He is led to this opinion by the form and arrangement of their epithelium, the presence of a layer of unstriped muscle, and their deep attachments, which seem incompatible with an origin from sebaceous glands. The author's paper is illustrated with some well-executed woodcuts of microscopical preparations.—*London Medical Record*, April 15, 1881.

—

Fatty Degeneration of the Cornea.

Dr. CUIGNET, of Lille (*Recueil d'Ophthalmologie*, Nov. 1880), describes a form of parenchymatous fatty keratitis, which, he believes, has hitherto escaped the notice of ophthalmologists. He narrates six cases of this affection, which he first noticed in Algiers, but subsequently recognized in Europe. It consists of white calcareous-looking patches on the cornea, which at times, however, may be yellow or gray, and present a smooth lustrous appearance. Their usual seat is the centre of the cornea, over which they gradually extend transversely. They commence by a small granular patch, which becomes gradually larger by the ag-

gregation of neighbouring patches. Their seat is directly under the epithelium in the substance of the cornea propria, within which they slowly increase in size and thickness. The first formed patch is generally the most superficial; those formed later both lie deeper and have a different tint. Vessels, which have their origin in either the external or the internal *cul-de-sac* of the conjunctiva, penetrate these patches, and at times give them a dark red pannus-like appearance. Together with these corneal changes there exist, as a rule, alterations in the ocular, palpebral, and ciliary conjunctiva. The affection is, as a rule, chronic; in one case, however, the author saw it assume decidedly acute symptoms. The most constant and best marked symptom is the impairment of vision, which, if the fatty patch occupy the whole of the pupil, may lead to complete obscuration, the patient having merely perception of light. The seat of the lesions is characteristic, being always near the centre of the cornea, and at a greater or less depth below the epithelium in the cornea proper. It is probable that the disease is incurable, either by treatment or by time, as the author has as yet met with no case in which the deposited matter has been reabsorbed. It remains permanent and innocuous, though in one case iritis was noticed as a complication; and it is probable that other complications, such as a glaucomatous condition, iridochoroiditis, etc., might supervene. Microscopically, the disease consists of a number of minute fatty particles mixed in some cases with crystals of cholestearine, which are gradually and progressively formed in the corneal tissue. Pathologically, it may be compared with the changes which take place within the arteries, and which lead eventually to endarteritis and atheroma. Etiologically, it is probably a manifestation of the strumous diathesis, provoked more immediately by changes in the conjunctiva, which affect the nutrition of the cornea. The differential diagnosis of this affection lies between (1) calcareous or metallic deposits; (2) cretaceous keratitis; (3) and plastic parenchymatous keratitis. The appearance, history, and course, will generally enable it to be recognized. The prognosis is unfavourable, and direct treatment is of little avail. Any causes of irritation in the conjunctiva, lachrymal passages, cilia, etc., should be removed: and if the opacity be over the pupil, iridectomy might be performed, and the opacity itself subsequently tattooed.—*London Med. Record*, April 15, 1881.

—

The Pathology of Glaucoma.

At the present time a point has been reached in the discussion of the question of the pathology of glaucoma at which it is worth while to summarize the facts accumulated, and to estimate the value of the theories which have been based upon them.

Glaucoma, whether primary or secondary, and however caused, is the generic name for a state of increased tension of the eyeball, due to excess of the intraocular fluids.

The older writers of the present generation—Donders, Bowman, and Graefe—contented themselves with the explanation that the condition was due to increased secretion of the intraocular fluids, occurring under certain conditions of vascular turgescence.

In 1876 Max Knies announced the discovery that the angle of the anterior chamber is almost invariably found closed in glaucomatous eyes; a fact which derived its significance from the observations of Leber, that the aqueous humour escapes normally by that channel. Max Knies attributed the closure to primary inflammation in the part.

These observations were mainly confirmed by Adolph Weber, who, however, regarded the cause of the closure to be the swelling of the ciliary processes.

Mr. Priestley Smith made an important contribution to the question by establishing, by careful experiments upon the fresh dead eyes of pigs and human subjects, that a very slight excess of pressure in the posterior chamber suffices to drive the ciliary processes forward against the periphery of the iris, and to close the angle of the anterior chamber; he also showed that the fluid of the posterior chamber passes by osmosis through the suspensory ligament, where it stretches between the lens and the ciliary processes, and escapes with the aqueous by the angle of the anterior chamber. It therefore follows that, in the absence of any local obstruction by new growths, inflammatory exudations, hemorrhage, etc., glaucoma may be mechanically caused by any increase of pressure in the posterior chamber.

Mr. Priestley Smith points out that this increase of pressure in the posterior chamber would be produced by any cause tending to diminish the "circumlental space" through which the fluid from the posterior chamber has to pass; and he suggests that this might be effected either by swelling of the ciliary processes alone, or by an increase in the diameter of the lens, or by a combination of these two factors. He has shown, by careful measurements of a series of lenses at various ages, that the diameter increases with the age; and the diameters of the lenses from three cases of primary glaucoma are given to show that they exceed the largest of the healthy series.

Dr. Brailey has contributed several papers to the pathology of glaucoma. He has drawn particular attention to the atrophy of the ciliary muscle, which in health has probably a regulating action over the blood-supply to the ciliary processes; he has also shown that the bloodvessels in the ciliary region are dilated and thin-walled. He attributes glaucoma to (1) increased inflow, due to "a visibly increased blood-supply, and sometimes to inflammation, especially of the ciliary body and iris;" and (2) to obstructed outflow, due to obstruction "in the region of the ligamentum pectinatum, or in some few to the exits from the perichoroidal space;" and to this not very clear statement he adds, "obstruction at the entrance of Schlemm's canal is ascribed, in most cases, to valvular action of the iris, induced either by its position or by the condition of it and the ciliary body."

After a careful consideration of the evidence, we think the following facts may be taken as proved: 1. The intra-ocular fluid has its sole channel of escape by the angle of the anterior chamber; 2. There is a normal current of fluid from the vitreous to the aqueous chambers through the suspensory ligament; 3. A very slight excess of pressure in the posterior chamber causes obstruction to the outflow of fluid by compressing the ciliary processes against the iris, so as to close the angle of the anterior chamber; 4. The angle of the anterior chamber in glaucoma is almost invariably found closed, or traces of its former closure may be observed; 5. The ciliary muscle is frequently atrophied; 6. The bloodvessels of the ciliary region are frequently dilated.

From these facts, we are warranted in concluding that the efficient cause of glaucoma is obstruction to the angle of the anterior chamber, which may be effected by the pressure of new growths, inflammatory exudations, hemorrhage, etc., or by the mechanical action of excess of pressure in the posterior chamber. Increased pressure in the posterior chamber is caused by increased blood-supply, occurring under conditions favouring vascular turgescence, and promoted by dilation of the vessels and atrophy of the ciliary muscle. Additional observations are wanting to confirm the view that an increase in the diameter of the lens plays an important part in the causation of glaucoma; so far as Mr. Priestley Smith's researches have been carried, there is nothing to contradict the hypothesis; but the number of cases hitherto examined is too small to permit of his conclusions

being accepted at present. Should further investigations confirm the view, the existence of an all-important predisposing factor will have been established.—*British Med. Journal*, March 15, 1881.

—

Tracheotomy for Diphtheria in Children.

In the recently published report of the Bethany Hospital in Berlin (*Langenbeck's Archiv für Klinische Chirurgie*, vol. xxv. page 815, November, 1880) Dr. KÖRTE, the author, gives the result of the tracheotomy operations during the year 1878. The number was unusually large, even for Berlin, and the disease was of a severe and dangerous form, especially during the latter half of the year. Thus, during the first six months there were 56 operations, with 30.3 per cent. of successful cases, while during the second six months there were 33 operations, with only 18.2 per cent. of successes. The disease was at its worst during the months of October, November, and December, during which period 62 operations were performed, of which only 12.9 per cent. recovered. The children, when admitted into hospital, were mostly very ill, presenting the ominous swelling of the submaxillary glands, slowed respiration, livid aspect, and other appearances of a serious diphtheritic intoxication. The disease was in many cases complicated by scarlet fever or measles. In the latter half of the year comparatively often some of the children presented an eruption like measles; but further observation showed that it was not measles, but rather a purplish rash, which quickly disappeared, was not infectious, and exercised no unfavourable influence on the diphtheria.

No marked differences between croup and diphtheria were remarked in the cases; the two were regarded as different stages of the same disease, and ran on into the other in the most varied manner.

Of the 149 cases, 34 (or 22.8 per cent.) recovered. The greatest mortality occurred among the children under three years of age. There were no cases under one year of age; 29 cases during the second year of life, with 3 recoveries; 28 in the third year, also with 3 recoveries. The percentage of recoveries gradually improved with the increasing age of the *opérés*.

The chief indication for the operation was the dyspnœa, and it was carried out without any regard to age; and was only withheld when extensive lung-disease precluded almost necessarily a successful issue. In the generality of the cases the operation had to be performed at once, owing to the very serious condition of the patients when first seen. For the most part, the trachea was opened below the thyroid isthmus. The after-treatment consisted in inhalations every two or three hours. The trachea was swabbed out with solutions of lactic acid, common salt or alum; and during the three months when the mortality was so high many other substances were tried, such as carbolic acid or thymol solution, etc. without any good results. No local treatment of the trachea was undertaken except swabbing, sucking out the membrane, and keeping the canula clean. As regards other local treatment, the author thinks it is unavailing, or of "extremely small value." The experience of former years teaches that the success after tracheotomy depends less on the treatment than on the nature of the epidemic itself. Thus, in 1877, under an exactly similar mode of treatment, in 88 operations there were 40.4 per cent. of successful cases.

Of the 115 deaths, 79 occurred within the first three days after operation; they were mostly due to descending bronchitis, and in a few cases to collapse. The remaining deaths occurred after more than three days, and were then brought about either by broncho-pneumonia or diphtheria of external parts.

The actual percentage of recoveries in relation to age was as follows: Under

two years of age, 10.3 per cent.; under three years, 11.1; under four years, 23.6; under five years, 27.2; under six years, 38.4; under seven years, 30.0; under eight years, 66.6; under nine years, 50.0; under ten years, 33.3 per cent. Twice the operation was performed on adults for this disease; both died of descending diphtheritis.—*Med. Times and Gazette*, April 9, 1881.

—

Inoculation of Syphilis by Razors.

M. Després (*Journal des Connaissances Méd.*, No. 49, 1880) has lately observed two cases of syphilis, in which the initial lesion was on the face, and in which contagion was supposed to have occurred during shaving. Case 1. D., aged 54, of sober habits, having never had any venereal disease, was shaved by a barber on July 11, 1880. On leaving the shop, the man noticed that he had three cuts on his chin. On the 14th he was again shaved, and the sore places bled during the operation. On July 25, the patient (having had nothing to do with women for ten weeks) noticed some swelling about the site of each cut, and applied a poultice. On September 1, he came under the care of M. Després, having been sent to him as a case of cancer. There were at that time three ulcers on the chin, surrounded by some red and rather hard papules. The ulcers were not painful. There was a hard gland beneath the jaw, but no further signs of syphilis about the body. On September 15 a general papular syphilide appeared, and was followed by mucous patches, etc. The second case was that of a man, aged 22, who came to Paris in May, 1880, having had no sexual intercourse for about two months. There was no history of any venereal disease. During his stay in Paris he was shaved by a barber every other day, but did not remember having been cut by the razor. About July 12, a little scab appeared in the furrow between the chin and upper lip. Beneath the scab was a sore with hard borders, and soon afterwards the patient noticed a lump beneath the chin. About August 10 M. Després saw the man, and diagnosed syphilis. On August 19 roseola appeared, and shortly afterwards mucous patches of the throat and anus.—*London Med. Record*, April 15, 1881.

—

Destruction of the Chancre as an Abortive Measure in Syphilis.

M. Henri Leloir, in a long and valuable paper (*Annales de Derm. et de Syphil.*, No. 1, 1880, p. 69) reviews and criticizes very fully the different experiments that have been made on the excision and destruction by other means of the initial lesion of syphilis with the view of preventing further development of the disease. The author also adds a very complete bibliography of the subject. The oft-quoted experiments of Auspitz and Unna, Kölliker, and others, are noticed, and their weak points are well brought out; the result being to show how little evidence there is, up to the present time, that general syphilis can be prevented, or even rendered milder in its course, by the destruction of the initial manifestation. M. Leloir concludes his paper with a brief account of a personal interview which he had with Ricord on the subject. This portion of the paper is particularly interesting, as it gives M. Ricord's matured opinion, and shows how entirely he has abandoned his former conviction, viz., that the destruction of the primary sore, within a short period of its existence, could prevent the sequence of general syphilis. Ricord now says "that he has completely abandoned the practice of cauterizing or of excising infecting chancres; that he considers the destruction of the infecting chancre to be absolutely useless at any period; as soon as it appears, before its appearance even, syphilis exists. If the penis were amputated on the appearance of the infecting chancre, syphilis would none the less be produced."—*London Med. Record*, April 15, 1881.

Treatment of Orchitis.

Dr. SABADINI, of Constantinople, following the plan of treatment advocated by Dr. Bourdeaux (*Gaz. des Hôp.*, 1881, No. 18), applied an ointment composed of one part of iodoform and ten parts of vaseline, with success in a case of gonorrhœal orchitis. The pain rapidly ceased, and the swelling disappeared in eight days.—*London Med. Record*, April 15, 1881.

—

Innominate Aneurism treated by Simultaneous Distal Ligature of the Carotid and Subclavian Arteries, with remarks on the behaviour of a Tendon Ligature.

At a recent meeting of the Royal Medical and Chirurgical Society (*Lancet*, March 26, 1881) a paper was read on a "Case of Innominate Aneurism treated by simultaneous distal ligature of the carotid and subclavian arteries, with remarks on the behaviour of a tendon ligature," by Mr. C. T. DENT. The chief object of this paper is to describe the changes observed in an artery tied with a tendon ligature. The parts were examined ten days after death.

The history of the case was as follows: S. L., an engineer, aged thirty-seven, was admitted with an aneurism of the innominate artery, the first symptoms of which had been noticed about twelve months previously. He improved at first under rest and iodide of potassium, but then as the growth increased the carotid and subclavian arteries were ligatured subcutaneously by Mr. Pollock. For the carotid artery catgut was employed as well as the tendon ligature; the subclavian was secured with a flat tendon ligature only. Both arteries were healthy. The aneurism improved, but the patient had at times very severe attacks of dyspnœa, and died ten days after the operation. A large ulcerated opening was found in the trachea, which did not communicate with the cavity of the aneurism. The carotid artery was dissected out and examined; the following points were observed: A very moderate amount of lymph was effused about the tied artery, though sufficient to bury the knot of the ligature. Well-formed clots were found in the proximal and distal ends of the completely obliterated vessel. No trace of the catgut ligature could be found. Much of the tendon ligature, where not in contact with the artery, was unaltered. The external coat of the artery was not ulcerated. This the author ascribes partly to the fact that tendon, like other animal ligatures, is capable of slight softening and swelling, and partly to the fact that new bloodvessels are early developed in parts lying close to the artery. The inner coats of the artery were ruptured. The tendon ligature, in many of the sections, was in most close connection with the artery, and in these places was infiltrated with small round granulated cells, which in places split up the fibrous material into longitudinal bands. Some of the cells seem to be more elongated than in others. In connection with these cells, and formed by them, were seen new bloodvessels. Here and there it appeared possible in the sections to trace bloodvessels passing across the line of connection, extending into the artery on the one hand, and into the tendon on the other. In conclusion, the author states that though he did not share in the objection urged against catgut ligature, still it seemed that tendon might furnish an animal material which would require less preparation than the carbolic or chromic catgut ligature, and which would probably be more constant in its behaviour.

Mr. BRYANT said the question of the use of flat ligatures involved the important principle whether it were necessary for permanent occlusion that the inner and middle coats should be divided, the point established by Dr. Jones; and he had himself some years ago come to the same conclusion that permanent occlusion

uld only be thus obtained. The flat ligature, which only compressed the ves-
l, would cause simply a temporary occlusion, long enough in some cases to allow
coagulation in an aneurism, but not in the other more difficult cases where
ature had to be resorted to. He compared the action of the flat ligature to
at of acupressure, which had been almost abandoned because (in the case of
vered arteries) it was frequently followed by secondary hemorrhage, the vessel
t being occluded long enough to allow of permanent clotting. Hence those
ses of aneurism which could not be cured by other means of compression were
t suitable for the application of the flat ligature. A similar mode of temporary
struction was devised by Mr. Dix of Hull some years ago, consisting in a wire
op placed round the artery and secured over a piece of cork. He thought much
idence was required before the fact of organization of an animal ligature could
admitted. He had examined six or seven weeks after ligature by carbolized
non-carbolized catgut, and although he had seen new vessels around the mate-
l he could not believe they had been formed at its expense.

Mr. SAVORY thought it strange if dead matter could be converted directly into
ing tissue. Several years ago it had been shown that masses of dead tissue
roduced into the living tissues became infiltrated with leucocytes; but the in-
ence was that the leucocytes had proceeded from the irritated living tissues,
l had absorbed the dead material. In Mr. Dent's case new vessels appear to
ve formed in the dead substances. The same criticism was applicable to the
ject of organization of blood-clot about which so much had been heard lately.
hn Hunter studied it, and some of his specimens were in the College of Sur-
ons' Museum; but in his case he dealt with living and not dead clots. It was
ferent in the case of large masses of blood-clot in wounds, masses which must
inert and act as foreign matter; which could not organize, but which might
replaced by new tissue proceeding from the living parts around. If an animal
ture could organize it would be important to know from what source it was
pared, and whether it was old or recent.

Mr. HOLMES, from his own limited experience, had arrived at a different con-
sion about the efficacy of animal ligatures to that of Mr. Bryant. He fancied
. Barwell had slightly exaggerated the difference in the action of a ligature of
shape as compared with a round one; for he (Mr. Holmes) had been able on
dead subject to divide the internal and middle coats partially or completely
means of the flat ligature when tied sharply. In the two cases in which he
d tried Mr. Barwell's ox-aorta ligature the vessel was permanently occluded,
e was a case where he had tied the iliac for rapidly enlarging iliac aneurism
h good result; the patient was long under observation (requiring two ampu-
ions before his discharge), but the aneurism remained perfectly occluded. In
other case, where the patient died in consequence of a debauch two weeks
er operation the ligature was found firmly attached to the artery, which was
ite closed. In a third case, where two arteries had been tied, they were found
luded by a diaphragm, as in Mr. Treves's case, the ligatures having dis-
peared. The evidence, so far as it goes, is in favour of the permanence of
se ligatures, and that an artery may be safely occluded whether the material
d be oxen aorta or tendon. It had been explained that the ligatures did not
emselves become organized, but that they disappeared, and were replaced by a
g of fibrous tissue. That such a replacement was not peculiar to healing under
tiseptics was shown by this case of Mr. Pollock's and Mr. Dent's, where no
tiseptics were used. It seems that these animal ligatures may be invaded by
ucocytes and caused to disappear, new tissue taking their place; and this is
w allowed by Professor Lister to be what is meant by "organization" of the
atures. So also in the case of blood-clot, the actual organizing elements and

new vessels being supplied from the surrounding tissues, the walls of the arteries, etc., surrounding the clot. It is quite possible that an animal ligature may excite this formative influence, and its results could not be compared with the effect produced by acupressure.
